McWANE PIPE

"I Finally Got Up Enough Nerve—"

TIME after time our customers report experiences that make our claims for McWane pipe sound too conservative.

"I finally got up enough nerve," a City Manager writes us, "to make my first purchase of McWane pipe." He had been listening to the Anvil Chorus.

Then when his 6-inch McWane pipe had been installed, he wrote:

"I believe I am safe in saying that the cost of laying is 50% less than it could have been had we used ..... pipe, as we have heretofore."

He used genuine McWane pipe and McWane Precalked joints. How is your nerve?

Municipal News and Water Works

Design, Construction, Maintenance and Operation of Municipal Works

INDEX

Vol. LXXVI, January-December, 1929

GENERAL INDEX

A

Accident Prevention, Statistics, Use in New York City ... 15
Accounting, Meter ... 161
Accounting Systems, Municipal Water Works ... 43
Acid Mine Water, Purifying ... 140
A Common but Fallacious Doctrine ... 203
Acquiring the Research Habit ... 315
Activated Sludge, Dried, Market for ... 458
Activated Sludge Plant Operation in Great Britain ... 397
Activated Sludge Practice in United States ... 304
Activated Sludge Process, English Notes on ... 468
Activation of Sludge by Mechanical Aeration ... 171
Aeration, Function in Water Purification ... 36
Aeration, Mechanical, for Activation of Sludge ... 171
Aeration, Stream-Flow for Sewage Treatment ... 381
Agitators, Mechanical ... 316
Air Circulation, Electro-Magnetic Theory of ... 355
Air Currents, Magnetism vs. Gravitation as a Cause ... 2
Airplane Surveys as an Aid to Plane-Table Work ... 514
Airport Design and Construction ... 332
Airport Floodlight, New Type ... 42
Air Valves, Pipe Line Inlet ... 57
Albany, New York, Typhoid Damage Suit ... 35
Algae, Identification and Control ... 199
Amarillo, Texas, New Sewage Disposal Plant ... 509
American Soc. C. E., Definitions of Terms Used in Sewerage ... 113
American Water Works Association, 1929 Convention ... 215
Ammonia, Experiences in Use as Preventive of Chloro-Tastes ... 437
Announcement of Articles on the Electron Theory of Weather and Allied Phenomena ... 508
A. R. B. A., City Officials' Division ... 59
Asphalt Joints in Brick Pavements, Pouring with Pressure Distributor ... 135
Asphalt Paving Methods Used in the City of Lancaster, Ohio ... 5
Asphalt Paving Practice, Latest Developments ... 325
Asphaltic Pavement Construction, Pittsburgh, Pa. ... 29
Aurora, Illinois, Sewage Disposal Plant ... 141
Automatic Chlorination, Results in Plant at Concord, N. H. ... 432
Automobile Tourists Camps, Sanitation of ... 324

B

Backfilling, Flushing for ... 234
Bacteria on Leather Washers ... 391
Bases, Flexible, for Brick Pavements ... 148
Beccari Plant, Scarsdale, New York ... 75
Bidders, Prequalification of ... 400
Bidders, Qualifying on Public Works ... 400
Billy, Adjusting and Meter Testing ... 474
Biochemical Oxygen Demand, Experiments in Determining ... 401
Boiler Operation, Water Treatment for ... 394
Bituminous Macadam, How to Secure Better ... 195
Bloomington and Normal Sanitary District, Sewage Treatment Plant ... 32
Boulder Dam Project on Colorado River, Premature? ... 506
Boulder Dam Project, Need of Further Study ... 272
Brick Pavements, Flexible Bases for ... 148
Brick Pavements, Old Relaid ... 185
Brick Pavements, Pouring Asphalt Joints with a Pressure Distributor ... 135
Bridge, Small Reinforced-Concrete, Methods ... 179
Bruckner and the Fritz Weather Cycles, The ... 99
Business Frontage and Relation to Population, Chicago Region ... 96

C

California Water Purification Plants Operating Experiences ... 53
Calumet Sewage Treatment Works, Sludge Disposal at ... 440
Cause of the Severe Winter Weather in 1928-1929 ... 209
Carbonate Hardness, Reduction by Lime Softening ... 289
Carbonation, Double at Water Softening Plant, Marion, Ohio ... 361
Carbon Dioxide Scrubber Water for Removing Sand Incrustation ... 417
Cast Iron Pipe, New Lining for ... 495
Cast Iron Pipe, Testing ... 447
Catskill Aqueduct, Manganese Dioxide Deposits in ... 389
Causes of the Bruckner and the Fritz Weather Cycles ... 99
Channel Crossing, Utilizes Flexible-Joint Pipe ... 229
Charlottesville, Va., Slow Sand Filtration ... 275
Chemical Treatment, Developments in 1929 ... 512
Chemical Treatment, Water Purification, Kansas City ... 31
Chicago, Experimental Filtration Plant ... 89
Chicago, Sanitary Aspect of Lake Michigan Diversion Case ... 469
Chlorination Automatic, Concord, N. H. ... 432
Chlorination of Deep Well Supply ... 153
Chlorination, Field, of New and Old Mains ... 425
Chlorination of Pipe Line Under Construction ... 331
Chlorinated Copper as Coagulant ... 227-246
Chloro-Tastes, Experience with Use of Ammonia as Preventive ... 437
Cincinnati Filters, Re-Sanding ... 456
City-County Consolidation, California ... 131
City Employees, Group Insurance for ... 121
City Governments, Financial Statistics for 1927 ... 112
City Highways, City Aid for ... 77
City Machinery, Centralizing Control of ... 19
City Manager and Municipal Research ... 120
City Officials Division, A.R.B.A., Objects of ... 59
City Pavement Design and Construction, Application Highway Research Results to ... 103
City Planning, Piecemeal ... 290
City Planning in Smaller Cities ... 189
City's Powers Defined ... 279
City Revenues and Expenditures ... 162
City Streets, Traffic on ... 68
City Traffic Congestion, Reduction ... 182
Coagulant, Chlorinated Copperas and Ferric Chloride ... 227
Coagulant, Chlorinated Copperas as ... 246
Coagulant, Flow of Regulated by Venturi Meter ... 296
Coagulation of Chemical in Water Purification, General Theory ... 435
Coagulation of Highly Colored Waters ... 231
Cobble Mountain Dam of Springfield, Mass. ... 280
Clarifiers, Mechanical ... 316
Colloids, Effect on Turbidity and Color of Water ... 393
Concrete Finishing Machine for Spreading Rock Asphalt ... 111
Concrete, Gray, Iron Oxide for ... 229
Concrete Pavement Over Poor Subgrade at Port Newark, New Jersey ... 343
Concrete Pavements, Curing by Sprinkling System ... 224
Concrete Under Water, Placing ... 232
Construction Outlook in Municipal Field for 1929 ... 9
Consumer, Water, Securing Good Will of ... 517
Contamination by Consumers' Water Uses ... 502
Contract for Well Drilling ... 511
Corrosion, Reducing, Staunton, Virginia ... 239
Corrugated Pipe Infiltration Gallery, Prescott, Arizona ... 218
Cost Accounting for Sewage Works ... 447
Cost Accounting System Minneapolis Garbage Collection Department ... 101
Cost Data, Sewage Treatment, Baltimore, Md. ... 423
Cost of Operating Ford Runabouts ... 80
Cost of Pumpage at Dubuque, Iowa ... 468
County Sanitary Districts, Kansas ... 297
Court Decisions ... 182
Court Decisions on Sanitary Matters ... 223-433
Cross-Connections, Final Report, New England Water Works Association ... 24
Cross Connections, New Developments in Safeguarding ... 329
Cross Connections, New York State ... 329
Currents, Action of on Floating Material ... 206
Cyclonic Storms, Parabolic Path of ... 3

D

Dam, Cobble Mountain, Springfield, Mass. ... 280
Dam, Earth, Selecting Materials for ... 387
Dam, Granville, Westfield, Mass., Construction Features ... 125
Dam, San Gabriel, Forbidden by State ... 538
Dam, Westfield, Method of Testing Soil ... 240
Day Labor Construction of Water Mains and Sewers, Methods and Costs ... 491
Death Rates, Relative, Villages With and Without Public Water Supplies ... 100
Deep Well Supply, Chlorination of ... 153
Definitions of Terms Used in Sewerage and Sewage Disposal Practice ... 113
Detroit Water Department, Personnel ... 79
Dewatering, Fine Screenings ... 532
Distributor News ... 45-88-125-171-213-225-271-273-323-359-407-509
Doctrine, Common but Fallacious ... 203
Dunbar Sewage Filter Bed ... 151
Dye, Use in Underground Leakage Surveys ... 86

E

Earth Current Surveys for New Pipe Lines ... 177
Earth Dam, Granville, Westfield, Mass. ... 125
Earth Dam, Selecting Materials for ... 387
Earthquake Cycles and Weather, Five Important ... 429
East Bay Water Company Filtration Plant ... 53
East Side Sewage Treatment Plant, Topeka, Kan. ... 339
"Economics in Engineering Schools" ... 77
Encyclopedia Britannica's Fallacious Argument Against Water Metering ... 459

Vol. LXXVI JANUARY, 1929 No. 1

Logic—A Challenge to Engineering Educators

Logic is taught in very few engineering colleges as a regular part of the courses. This seems to mean either that "the science of thinking" is not regarded by engineering educators as being a necessary part of an engineer's education or that it can be best acquired as a by-product of certain courses of study.

There is no doubt that pure and applied mathematics furnish excellent training in certain kinds of reasoning. But any one who has carefully investigated the subject of logic could scarcely fail to see that mathematics is insufficient as a training in logic. For example, mathematics does not discuss the use of language as a tool of reasoning. All books on logic stress this phase of the art of correct thinking, and whatever their weaknesses, their strength in this particular branch is undeniable. Indeed the syllogistic logic is little else than a sort of glorified grammar for thinkers. Lawyers receive an intensive training in the accurate use of language. Engineers, as a rule, do not receive such a training, and the resulting weakness is often very serious. Although the original object of language was to convey ideas (or, if you agree with that French philosopher, to conceal them), its main use to a thinker is to assist him in thinking correctly. Anyone who has studied algebra can appreciate the confusion and error that would occur if the symbol X were used to denote a velocity in the forepart of a demonstration and were carelessly changed later on to denote space traversed without regard to time. There are countless examples of just that sort of switch in the meaning of words used in discussions. Even worse, and much more common, is the failure to define important words. This is equivalent to assuming that the reader knows what you intend to signify by the letter X without your telling him. Curiously enough, if you are asked to define some important word, you will usually find that you can not do it off hand in such a manner as to stand any rigorous test.

Take, for example, the word conceive, and try to define it. Unless you have previously given a good deal of thought to its meaning you will almost surely fail to define it properly. Yet, it is a word that you probably use frequently. You speak of great distances, such as the distance to a star, as being inconceivable. Yet you do not hestitate to reason about such great distances by comparing them with one another, and with small distances. Do you admit, then, that you can reason about inconceivable things? If so, you can be easily run into a logical cul-de-sac. Then your only escape is by revising your statement of inconceivability, so that it amounts to this: A great number is not picturable at one glance, but may be conceived by successive additions (or multiplications) each of which is picturable. Conception, in other words is not necessarily a mental instantaneous picture but it may be a mental moving picture that involves a long time.

We have used this particular example because there have been many important scientific debates that have really hinged on the meaning of the word conceive, and in most of those debates not one of the debaters has seen that it was necessary to define the word conception.

We learn the meanings of most words by hearing them used in association with things and with other words that we already know. Hence all of us have acquired the sloppy habit of thinking that there is no need of carefully defining commonly used words. We take it for granted that we know their exact significance and that our hearers also know it. It is somewhat of a jolt to our confidence in this respect when we find that we can define relatively few words with exactitude. Just this sort of jolt is what we get when we study logic, and few of us ever get it otherwise.

Unfortunately most of the existing text books on logic devote only a single chapter to the subject of definition, and have little to say about research logic. On research logic or inductive logic as logicians have preferred to call it, Mill's discussion has been copied by other authors, almost slavishly, and it is an altogether unsatisfactory presentation of what should be the most valuable part of logic.

Doubtless it is the obvious defects of text books on logic that have served to turn engineering educators away from the study of it as a desirable part of an engineering course. But this very weakness should encourage professors of engineering to attempt to convert logic into the powerful educational instrument that it seems susceptible of becoming.

"Logic for Engineers," as several professors have remarked in correspondence with the editor, is about as poor a title for a book as "English for Engineers." English is English, and logic is logic. True, but the general treatises on logic have been so unsatisfactory to scientific men that some distinguishing title seems desirable for any new book that is to differ much from the Aristotelian syllogistic logic and Mill's inductive logic. Perhaps a better title may be "Research Logic"; at any rate the editor has in preparation a book that will bear that title.

All productive thinking calls for some amount of research on the part of the thinker, whether it be the thinking involved in designing a culvert or the thinking involved in the discovery of a law of nature. In every case there should come first the gathering of data that seem to bear upon the problem. During the process of data gathering, theories, new or old, should direct the classifying of the data, and the interpretation of their significance. New relationships may then be discovered, or old ones may be seen exemplified. Each problem, however small, becomes one of growing fascination, and takes on an importance that drives the investigator to do his best in solving it. Contrast such an attitude with the more common one of merely seeking some sort of a solution that will "get by." Contrast the method of thorough search for pertinent data with the more common one of presenting the engineering student with all the required data either in the

statement of the problem or in some handy reference book.

Existing text books on logic furnish little more than the barest hints on the gathering of data. Their authors seem to think either that this is not a teachable process or that every student has an instinct that will lead him in such searches. Yet data gathering, the editor finds, is by all odds the most difficult process that confronts the reasoning mind. That it can be taught is almost self-evident. That it is not ordinarily taught is well known. That no instinct leads the average man, or even the educated man, to become a thorough collector of pertinent data before drawing his final inferences, is a matter of such common knowledge that we need not dwell upon it. In fact science came into existence only after a few men, here and there, saw clearly the necessity of gathering and classifying facts relating to the properties of matter. Even yet the percentage of men who see this necessity is pitifully small. The rapidity of our whole future economic progress will depend mainly upon the rate at which this percentage will be increased.

The interpretation of data thus gathered is another branch of research logic, and one whose importance is scarcely less than the gathering of the data. Such interpretation takes the form of scientific theories. It is the editor's belief that there is more than "scientific intuition" involved in originating correct theories, and that methods of originating such theories can be taught. "Scientific intuition" itself may be nothing else than good method coupled with good memory; the former being teachable, the latter susceptible of being improved by training.

Magnetism vs. Gravitation As a Cause of Many Air Currents

Are barometric gradients the main causes of our cyclonic air currents, or are they the effects thereof? We do not recall ever having seen such a question in print before, yet we ask it in all seriousness. It has been taken for granted that all air currents on our globe are caused by the force of gravitation, somewhat modified at times by centrifugal force. The barometer registers differences in air pressure and all winds are supposed to be the result of such differences. While it is undeniable that many winds are merely convection currents, it may be that the major movements of air are electromagnetic phenomena.

Elsewhere in this issue it is shown that certain (perhaps all) cyclonic storms travel in parabolic paths. It will puzzle physicists to explain such a path on the theory of gravitative pressure and centrifugal force. Yet it is readily explainable on an electromagnetic hypothesis.

The cyclonic rotation of storms has been explained by the hypothesis that centrifugal force is stronger in the lower latitudes. But what becomes of this explanation when applied to a small whirlwind a few feet, or even a few inches, in diameter? Is a difference of a foot or so in latitude sufficient to account for one of those very intense though small dust whirls that are so often seen?

If the whirling motion of cyclonic storms finds unsatisfactory explanation in treatises on meteorology, even more unsatisfactory are the reasons given for the eastward trend of such storms. How does it happen that they travel faster than the earth rotates? Is it because they are carried along by upper air currents? Then why do the upper air currents move eastwardly? And why do cyclonic storms advancing in a series have velocities inversely proportional to their distance apart?

Cyclonic storms have centers of low pressure, and they are followed by anticyclones that have centers of high pressure. Why don't the "highs" flow into the "lows"? What conceivable arrangement of high and low pressure areas can cause a continuous eastward movement of both high and low pressure areas? How can the earth's rotation impart a continuous and greater eastward velocity to air than the earth's rotative velocity?

Our search for satisfactory answers to these questions has been fruitless. If you are weak in physics and strong in credence when authorities speak, you may find satisfaction in some of the answers, but if you insist on physical demonstration that carries conviction, you are certain to be disappointed.

Sunspots are cyclonic storms in the sun's atmosphere. They have many features that are strikingly like our cyclonic storms. Since meteorologists explain the latter as being the results of flow of cold polar air equatorward, we wonder how they would explain the former, sunspots. How would they explain the rotation of sunspots? Since sunspots move forward with exceeding slowness, centrifugal force could hardly account for their rotation.

Sunspots are powerful electromagnets, as Hale has shown. It is therefore probable that their rotation is an electromagnetic phenomenon. If so, analogy suggests that their first cousins, our cyclonic storms, are also electromagnetically rotated. We know that all air contains "free" electrons. We know that "free" electrons in motion constitute an electric current. We know that "free" electrons in rotary or orbital motion constitute an electromagnet. So we may infer with certitude that every one of our cyclonic storms is an electromagnet. What we do not yet know is their magnetic strength. But when we see them rotating and progressing in a manner that shows great power, we may infer that our cyclonic storms are whirling masses of ionized air that are powerfully electromagnetic, taken in the aggregate. This of course does not imply that a relatively small volume of such air will show great magnetic force. We should no more expect that than we should expect to find a powerful gravitative pull between two clouds.

If electromagnetic force rotates and propels the air of our cyclonic storms, and if periodic changes in the size and intensity of such storms account not merely for weather changes but for climatic changes, it follows that electromagnetism is fully as important a factor as convection currents. Indeed it seems to us to follow that convection is to be regarded as less important.

Finally, does it not seem probable that if air is rotated electromagnetically, the low pressure within such a rotating mass is a result of rotation? If so, it must follow that many important barometric gradients are the results of air currents, and not their cause.

W. P. Gillette

The Parabolic Path of Cyclonic Storms

By HALBERT P. GILLETTE

AS announced in a previous article, I believe that all cyclonic storms are rotated by the electromagnetic energy of the earth. Many storm phenomena are thus explained. That cyclonic storms are propelled eastward and toward the equator electromagnetically is a corollary of this electromagnetic whirl theory.

Being an electromagnet itself due to the presence of free electrons in the vortex of air, a cyclonic storm would be driven from the more intense parts of the earth's magnetic field to the less intense, or toward the equator. It would also be propelled laterally.

The resistance of the air results in a constant velocity of a storm in its eastward or latitudinal direction, just as a falling raindrop soon attains a constant velocity. But the force that propels the storm meridionally toward the equator has a negative increment, due to the opposite polarity of the two ends of the magnetic field of the earth, the resultant being zero at the magnetic equator.

Hence we have a phenomenon that resembles the movement of a jet of water ejected horizontally under a constant head. The constant horizontal velocity of the jet corresponds with the constant latitudinal velocity of the cyclonic storm. The steadily increasing vertical velocity of the jet corresponds with the steadily decreasing meridional velocity of the storm. Hence, since the path of a water jet is a parabola, that of a cyclonic storm should be a parabola, unless changed by other wind movement. As a matter of fact this is the case.

For example in Clayton's "World Weather," p. 125, there is shown the path of a cyclonic storm from Finland to Vladivostok, north of Korea. This storm center moved about 15 degrees south while travelling about 60 degrees east; and taking various coordinates along its path from Finland, its eastward distance of travel varied as the square of its southerly distance, showing the curve to a parabola.

This law of parabolic paths of cyclonic storms can be used to determine the point of origin of such storms, as well to forecast the path from known coordinates.

Clayton (p. 269) states, as an empirical law, that the velocity of a cyclonic storm center varies inversely as the "length of the solar cycle" of activity that caused the storm. He means (p. 267) that the velocity of a cyclonic storm varies inversely as the period of time between successive storm centers as they move in a periodic series.

Clayton gives no reason for this law, other than an analogy between the velocity of ocean waves and storm waves (p. 112) but the analogy, it seems to me fails to apply, for the velocity of ocean waves increases as the distance apart increases, whereas the converse is true of storm "waves."

Clayton (p. 203) thinks that cyclonic storms are carried eastward in temperate latitudes by the general eastward trend of the air. If so, why do cyclones not travel northeastward, in the northern hemisphere, instead of southeastward? The northeastward trend of the north temperate zone itself calls for explanation, and no satisfactory explanation is to be found in the heat convection theory. We have northeasterly equatorial trades in the same hemisphere that we have southwesterly temperate winds, so that we can not invoke the earth's centrifugal force to explain the one without running into difficulties over the other.

The fact is that the convection theory of cyclonic storms falls down at nearly every turn, and no amount of bolstering with other forces, such as centrifugal force, serves to keep it on its feet. On the other hand, the electromagnetic theory explains every characteristic of such storms; and, as above indicated, it explains some characteristics with mathematical precision.

Let us consider Clayton's law of reduced storm velocity when storm centers are farther apart. Convection yields not the slightest clue to such a law; but electromagnetism does. Since parallel electric currents attract one another, and since free electrons in air moving in mass constitute parallel electric currents, a rotating mass of air should tend to concentrate into a belt or ring of rotating air having a somewhat quiescent center. Moreover, the greater the velocity of rotation, the greater the tendency to such concentration. But the greater the concentration and the greater the velocity, the stronger the electromagnet. The stronger the electromagnet, the more rapidly it is propelled by any other magnet. Hence cyclonic storms of small diameter travel more rapidly because of the greater intensity of their electromagnetism, also because their small diameter reduces the friction of the quiescent air through which they travel.

The magnetic needle shows varying deflections during storms, but this has been regarded as a secondary phenomenon, resulting presumably from the static electricity caused by friction, whereas I regard such magnetic changes as being a primary phenomenon resulting from the motion of free electrons with the air currents.

It is not impossible that the whirling belt of air that constitutes a cyclonic storm may itself be rising but slowly if at all, and that the air that is ascending is the air within the whirling belt, where rarefication is caused by the flow of air toward the rotating belt. But I am inclined to think that electromagnetism plays a very important part in raising the current of ionized air.

Humphrey's "proof" that electricity can have little effect on air motion is based solely on consideration of the attraction of electrostatic charges. Hence it has no bearing whatever on air movements caused by electromagnetism, a phenomenon that he seems to have overlooked.

Cyclonic storms originate in high latitudes and travel eastward and toward the equator, dying out in lower latitudes. This phenomenon bears strong resemblance to sunspots, except that the velocity of sunspot travel is relatively slow. Perhaps this difference in velocity is explainable on the theory that the upper and lower fields of magnetism more nearly balance in their effect upon sunspots than is the case on the earth. Incidentally this theory may explain the periodic reversal of polarity of sunspots, discovered by Hale. It can be seen that sunspots (being electromagnets) must tend either to repel or attract the ionized atmosphere above them (which, through its rotation causes the upper magnetic field). Hence a predominance of sunspots of a given polarity would warp the upper magnetic field. It is easy to picture a consequent alternate up and down warping of the upper field, so as to cause the lower (and less movable field) to predominate in its magnetic effect when the upper field is warped to a higher elevation. This would cause a periodic alternation in the rotation of most of the sunspots in the sun's two hemispheres, exactly as Hale has found to be the case.

Sunspots are so closely analogous to our cyclonic storms that each may be used to explain the other, and thus lead to a much better understanding of both.

Record Fabricating Job.—A record fabricating job was recently executed on the apartment house structure covering the block front on Madison Ave. between 70th and 71st Sts, New York City. This was accomplished by the Hay Foundry & Iron Co. for the Tishman Realty & Construction Co. The building is 11 stories in height. The steel work represented the assemblying of 9,762 pieces of steel and the driving of 36,200 rivets in the field. The plot occupied by the building is 30,000 sq ft. Approximately 2,200 tons of steel were used. The steel work was started Sept. 17 and the erection of steel completed Oct. 11, 1928.

City Officials' Day at Cleveland Convention

Important Reports to Be Presented and Discussed

THE city officials' division of the American Road Builders Association will hold its first annual meeting on Jan. 15, during the 26th annual convention and road show of the association. The division was organized June 8, 1928. Its aim is the standardization of city street and highway construction, maintenance and operation, including traffic regulation. At the meeting on Jan. 15 the various standards committees will present their reports as outlined below—the result of the year's work in each particular field. The city officials present will have the opportunity to discuss the reports, bring out such points as may be involved in their own particular problems and receive the benefit of the personal contact and experience of others.

Program for City Officials' Day.—The program announced for the city officials' day includes the following:

"Trend of City Government," Wm. R. Hopkins, City Manager, Cleveland, Ohio.—A subject presented by the able manager of a progressive city, whose growth and advancement have been phenomenal. This is an opportunity to learn how it was done from a man who will speak authoritatively on this subject.

Report of Committee on Administration, Organization and Finance; Chairman, H. C. Whitehurst, Assistant to Engineer - Commissioner, Washington, D. C.—It is the aim of this Committee to present clearly and logically the methods of administrating and financing city highway work. The report is based on a survey of present practice in more than sixty cities, selected as typical examples. These sixty cities were selected after information had been collected from 326 cities in 46 states and the District of Columbia. The report is informative and will be used as the groundwork for the future activities of this important committee.

Report of Committee on Design and Construction; Chairman, Geo. B. Sowers, Deputy Commissioner, Division, Engineering and Construction, Cleveland, Ohio.—The message of this report will be the need of standardizing and adopting by cities best present construction methods. It will include the principal types—asphalt, bituminous concrete, cement concrete, brick and block pavements. Important discussions of these pavement types will follow the committee report, led by persons who have made national surveys of each. Contrary to general belief, construction methods vary greatly, as does the selection of type for a specific class of traffic. The conclusions of this report, which are based on the summarization of present practice, will be of immense practical value to those who attend this session.

Report of Sub-Committee on Sub-Grades, Foundations and Bases for Pavements; Chairman, C. A. Hogentogler, Senior Highway Engineer, Bureau of Public Roads, United States Department of Agriculture, Washington, D. C.—The basic principles of success and failure in pavement foundations and subgrades will be discussed in this report, which is characterized by simplicity, directness and practical application. Few reliable sources of information have been overlooked by its author, who for many years has studied the perplexing problems of subgrade and foundation. To learn first hand the concise information contained in this report may mean the saving of thousands of dollars to those cities which can profit by the experiences of others.

Report of Committee on Maintenance; Chairman, C. E. Myers, Director of Transit, Philadelphia, Pa.—No subject is more important than maintenance. The report of this Committee, together with the selected discussions by city engineers of national prominence, will be of inestimable value to those who desire more information on the maintenance of city streets. Maintenance is an ever-present problem, which involves a wide variety of methods in modern practice. Some of these methods are good, others are better. A report on this subject, followed by open forum discussion, cannot fail to show those methods which have been found adequate through practical usage.

Report of Committee on Traffic; Chairman, M. O. Eldridge, Assistant Traffic Director, Washington, D. C.—The traffic problem is so serious that the United States Department of Commerce has codified recommended practice. This Committee report will present facts and conclusions which are drawn from the "Hoover Code" and other authentic sources of information. The importance of solving traffic problems is so vital to every city official that this report must be of unusual interest. The Chairman of this Committee, by his intimate contacts with the principal agencies which are attacking traffic problems, is especially qualified to present the situation. The conclusions of this report are not local in character, but embrace the entire United States. They will be of interest and usefulness to officials and manufacturers alike.

The Convention.—The 26th Annual Convention and Road Show of the American Road Builders Association which will be held Jan. 14-18 at Cleveland, O., will bring together the engineers and road builders from all over the United States and Canada, as well as from foreign countries, for the purpose of exchanging ideas on the most recent methods of highway construction, operation and maintenance. The program at the 1929 convention will consist of reports of committees identified with the several divisions, as well as reports and papers on subjects of general interest. These reports will constitute the year's work on the different subjects and will present the latest methods and standards.

The Road Show.—The exposition which is held in conjunction with the convention, is the largest demonstration of road-building machinery, materials and methods in the world. It makes available for personal inspection all the newest and most up-to-date equipment and materials used in the road-construction and maintenance field. Over 500 carloads of the latest developments in road building machinery, equipment and materials, comprising the world's largest road show, will be on exhibition at the Public Auditorium, Cleveland, O. The space available for the road show has been augmented by the addition of a new wing to the Public Auditorium and this building, together with the Central Armory, will make possible the display of a far greater number of exhibits than ever before—in all, there will be more than 200,000 sq. ft. of floor space occupied by exhibits of machinery, materials and equipment, the most complete and comprehensive exposition and demonstration of this type ever held at any time and any place.

The Convention will be officially opened by Colonel R. Keith Compton, President of the American Road Builders' Association. The delegates will be welcomed to Cleveland by the Mayor of that City, Honorable John D. Marshall.

Tuesday, as stated above, will be City Officials' Day; Wednesday will be County Highway Officials' Day and Thursday will be Pan American Day. On these days the various sessions of the convention will be devoted to the presentation of reports of committees, and papers and addresses, by engineers and officials prominent in the highway field. These reports and papers will deal with the construction, maintenance, operation and financing of roads and streets.

In addition to attending the meetings on Tuesday, city officials should not overlook the opportunities afforded at the sessions to be held on Wednesday and Thursday under the auspices of the Contractors, Engineers and Officials, County Highway Officials and Pan American divisions.

Asphalt Paving Methods Used in the City of Lancaster, Ohio

How New Pavement and Resurfacing are Handled

By WALTER W. GRAF
City Engineer, Lancaster, O.

THE slogan of the City Engineering Department of the city of Lancaster, O., is "Better Pavements Without Materially Increasing the Cost." In city paving work we are at a decided disadvantage when compared with state highway work on account of our many widths of streets, types of construction, manhole covers, valve boxes, existing improvements, street railway tracks, street intersections, different curb elevations and grades, etc.

Sub-Grading.—The first thing of importance in securing a good pavement is a uniform subgrade, which will insure us a uniform specified thickness of foundation and wearing surface. This can only be obtained by having the subgrade cut true and parallel to the wearing course. We are securing good results at a very small cost by making a light wooden template, cut to the contour of the street, with steel teeth set 2 ft. on centers across same so that the teeth will score the subgrade at its proper elevation when the template is resting on the curb and pulled along the street. This will cut the contractor's cost of fine grading, as no time is wasted in measuring and the most stupid workmen cannot go wrong. This not only cuts fine grading costs but insures a uniform thickness of foundation which is essential, as a foundation, like a chain, is no stronger than it weakest link.

The Base.—After the subgrade is cut to the proper contour and elevation, the next essential thing is to finish the concrete base parallel thereto. For finishing concrete base, we use a heavy wooden, steel shod, "strike off" template pulled by the mixer and follow this with a light wooden "tamping" template, cut to the contour of the street and operated by a man standing on each curb. This method will finish the base, with a few exceptions, without the use of hand floats. This method of finishing leaves a smooth surface which is roughened by the use of a wooden tamper 2 ft. in diameter with a coil of ⅝ in. cable attached so as to leave a print of the cable in the base. We find this to be a splendid method of preparing concrete base to receive sheet asphalt pavements. We believe that the more nearly perfect the contour of the concrete base the more nearly perfect will be the riding qualities of the finished asphalt surface. A perfect base not only gives the "rakers" a guide, but insures a uniform thickness of asphaltic wearing surface and therefore uniform compaction under the rollers. It has been hard to persuade either foreman or workman that a concrete foundation to be covered with asphalt, has any need to be true to contour. If there is a defect, "why not make it up in the binder," is the question asked. This leaves great variations in density and thickness with the resultant disagreeable waves in the surface. For these reasons, we check car concrete base with string lines at 8 ft. intervals behind the finishing template.

Pavement on First Court; 1 In. Binder, 1½ In. Top on 6 In. Concrete Base

Binder and Surface.—Where concrete base is finished as above specified, we find that more than 1 in. of binder is unnecessary and therefore always lay 1 in. binder on new work. On resurface work we find that it will require approximately an extra 100 lb. of binder to bring the old brick foundation up to the proper contour to receive a 1 in. binder. On resurface work, before any binder is laid we thoroughly clean the old brick street with water from a fire hose operating under a 100

Pavement on South Columbus St.; 1 In. Binder, 1½ In. Top Resurface Over Old Brick

lb. pressure. This not only cleans the foundation, but opens the interstices between the brick which insures perfect bond between the foundation and the binder. The binder course is inspected with a "straight edge" the same as the top and must show the same degree of smoothness. The top surface or wearing course, when laid must not vary from a 10 ft. straight edge more than ¼ in. This requirement, frequently and carefully checked by the inspector close behind the rakers, has the effect of creating a rivalry among these workmen and insures constant attention to one of the all important operations in the laying of a sheet asphalt pavement. With careful longitudinal raking and transverse luting with a 5 ft. wooden lute on a long handle followed by thorough longitudinal and cross rolling, this standard is not hard to attain and costs no more than work half done. Many otherwise well constructed pavements are condemned by the public on account of a rough surface. The citizenship judge a pavement by its surface smoothness and ease of riding.

For the past few years with the use of these simple and inexpensive methods, good washed sand and gravel, tested cement, stone, sand and asphalt, we have been able to sell the citizenship of Lancaster on asphalt streets where only six years ago the first asphalt pavement was laid. We have open specifications and have laid both oil and lake asphalts. For the past two years all asphalt streets in Lancaster have been laid by Brewer & Brewer Sons, Contractors, of Chillicothe, O., using Texaco asphalt.

Ohio Filtration Men Meet

The 8th annual meeting of operators, chemists and others interested in the filtration and water softening plants of Ohio, held at the Argonne Hotel, Lima, Nov. 1-2, drew a larger attendance than any previous conference, with about 100 registered. Practically all of the 58 filter plants and 21 water softening plants in the state were represented. In addition, representatives of several municipalities contemplating water supply improvements were present. After the meetings a visit was made to the Lima filtration plant and many also drove to Piqua to inspect the new water softening plant there.

Officials chosen for the coming year are: Chairman, C. T. Kaiser, Newark; vice-chairman, A. E. Hess, Alliance; secretary-treasurer, James M. Montgomery, Piqua. Other members of the executive committee are Frank S. Taylor of Defiance and J. H. Wenger of Westerville.

The conference favored Columbus for the 1929 session, but decision as to the place of meeting is left to the executive committee.

Short Courses for Sewage Plant Operators

Rutgers University, New Brunswick, N. J., is again offering short courses for sewage plant operators. These courses will be held Jan. 14-26 under the direction of the College of Engineering in co-operation with the New Jersey Sewage Works Association and the New Jersey State Board of Health.

This is the third consecutive year that these courses have been given and the attendance has been steadily increasing. The work of the courses is planned so that there is approximately 35 hours of laboratory work and 12 to 15 hours devoted to lectures and recitations. In addition there will be eight round-table discussions of various phases of plant operation.

Attendance to these courses has been largely from New Jersey although there have been many from outside states as far west as Ohio.

The purpose of the Rutgers Short Courses for Sewage Plant Operators is primarily to offer intensive training in the fundamentals of sewage disposal and sewage plant operation. It is an opportunity through which plant operators may better qualify themselves to solve their individual problems; to increase their general knowledge of sewage disposal and its relation to the public health and thereby enable them to discuss more intelligently, with the officers of their municipality the needs and necessary changes in their plants. Furthermore, it will afford opportunity for those men wishing to become operators, to qualify themselves to meet the requirements of the New Jersey State Board of Health for such positions.

The short courses will extend over a period of two weeks, beginning with registration on Monday, Jan. 14, and ending Friday afternoon, Jan. 25. Classes will be scheduled daily from 9 to 12 in the morning and from 1:30 to 4:30 in the afternoon and ending at noon on Saturday.

The courses are as follows:

Course I — Professor Lendall

Lectures and recitations—16 hours.

The elements of design and construction of different types of treatment plants—details of operation and maintenance.

Laboratory exercises—23 hours.

Prof. van der Meulen

Lectures and demonstrations by the instructor and actual determination and tests by the student. The work will cover the principles of chemistry as applied to sewage treatment, determination of solids, digestion of solids, hydrogen ion concentration, biochemical oxygen demand, sterilization and other phases of operation with which the operator is concerned.

Course II — Professor Lendall

Lectures and recitations—6 hours.

Comparison of the design of existing plants with operation data. This course is planned to show how details of design may be changed to improve operation and efficiency.

Laboratory—40 hours. Dr. Rudolfs

A continuation of Course I with more detailed study; the adjustment of the reaction of a tank by addition of lime, odors and their control, biochemical oxygen demand and Bacteriology. Some time will be given to water purification.

Course III—Sewage Plant Testing

Professor Lendall and Dr. Rudolfs

Lectures—6 hours. Laboratory—35 hours.

Methods for making extended tests on sewage plants. Sampling and preservation of samples. Analysis and interpretation. Measurement of stream flow and stream pollution.

The many problems of plant operation and design will be treated in informal discussions for which definite periods will be scheduled. These discussions will be led by men of experience and who are thoroughly acquainted with plant conditions in New Jersey and nearby states.

There are no educational requirements for admission to any of the courses.

Admission to Courses II and III will be based entirely on training and experience.

A nominal fee of $5 is charged for admission to any course.

Prof. H. N. Lendall is in charge of the courses and applications for enrollment may be obtained by addressing him at Rutgers University, New Brunswick, N. J.

Perils of British Streets

A deputation from the British National Safety First Association recently waited upon the minister of transport to ask for a full inquiry into the causes of street accidents, and to make suggestions with a view to reducing them, according to the London correspondent of The Journal of the American Medical Association.

"In 1922," the correspondent writes, "there were in Great Britain 2,728 fatal and 79,197 non-fatal accidents in the streets owing to vehicular movement. Last year the number rose to 5,329 fatal and 148,575 non-fatal. It is stated, however, that the rate is slackening in proportion to the number of motors and drivers licensed.

"Last year the vehicles most involved in fatal accidents were private cars and taxicabs, the proportion being 1,509, or more than a fourth of the whole. Motor vans and lorries, however, made a good second, with 1,104 fatalities. Motorcycles, which many regard as dangerous, were concerned in 784 fatal accidents. Motorbuses and coaches, which carry much of the heavy passenger traffic, figured in only 613, while horse-drawn vehicles were the cause of only 193.

"In London there were 293 street fatalities during the first three months of the current year, compared with 214 in the corresponding period last year. Excessive speed is declared to be the most fruitful cause of accident, though want of care or hesitation on the part of pedestrians is held to contribute to a great extent."

New York's First Printed Traffic Regulations.—New York's first printed traffic regulations were issued in 1903. Before that time the unwritten law of "keep to the right" was the only rule of the road.

How a Water Company Increases the Number of Its Customers

Mutual Benefit of Cooperation Between Utility and Plumbers

By NORMAN J. RADDER

AS a result of cooperation between the master plumbers of Indianapolis and the Indianapolis Water Co., more than 250 new customers have been added to the company's service list in the last six months.

For years Frank C. Jordan, Secretary of the Indianapolis Water Co., has had the idea that cooperation between the company and the plumbers would bring mutual benefits. He had some difficulty at first in making the plumbers see the point. Finally, however, they agreed to try it out.

Last spring, Mr. Jordan made out a list of the property owners in one section of the city who did not have running water in the home. In many cases they had a hydrant in the yard.

He turned this list over to G. T. Watson, Secretary of the Indianapolis Merchant Plumbers' Association, who worked up the list according to neighborhoods and then told his association members to get on the job.

They did and sold 250 complete bathroom outfits the average value of each being $250. Thus the plumbers made sales of $50,000 and the water company got 250 new customers.

In addition to giving plumbers the names of prospects, the water company has carried on an extensive advertising program in two of the Indianapolis daily papers and has also turned over much of its lobby space to a display of plumbing fixtures. These displays are installed by jobbers in Indianapolis and are changed frequently. Just recently Mr. Jordan called attention to the fact that more of the lobby space should be used for this purpose.

"I have to keep after the dealers all the time to keep leaflets descriptive of the equipment here to be picked up by the 50,000 customers who pass through the lobby each month to pay their water bills," says Mr. Jordan. "The people who came here are the best possible prospects for additional plumbing fixtures. We are glad to give the plumbers the opportunity to put equipment in the lobby, because if it helps them it gradually gets around to help us. We are anxious to sell more equipment to the home owner who has only a kitchen sink."

One corner of the lobby of the office of the Water Company has a most attractive display of a complete bathroom in a delicate shade of lavender with chromium fittings. A recessed tub is in the corner with a pedestal lavatory on one side and a toilet on the other.

Bathroom Equipment on Display in Lobby of Indianapolis Water Co.

View of Portion of Lobby of Indianapolis Water Co.

There is an attractive tile background. In another part of the lobby is a pedestal lavatory in a soft yellow shade, while across the lobby is a wall hung lavatory in green hung to a standard than can be moved around the room.

Mr. Jordan conceived the idea years ago that plumbers ought to sell equipment on the partial payment plan. It was only within the last year that he obtained general acceptance of the idea. No doubt it was the fact that plumbing equipment could be obtained on easy time payment that enabled plumbers to sell 250 bathroom outfits.

A few years ago, the Public Utilities Commission authorized the local water company to install meters in every building in the city of Indianapolis and they have been gradually enforcing this rule. Recently the water company decided to take different sections of the city and notify every user in that district that it was compulsory to install meters by a certain date.

Mr. Jordan, realizing the possibilities that such a situation offered to the plumbers, called in the officials of the Master Plumbers' Association, and together outlined a plan whereby a duplicate of a certain number of the notices sent out was given to the plumbers in the different districts with the understanding that it was not just for the small job of making the meter connection, but for the opportunity of selling these people some more plumbing work and especially the opportunity of being in the home and able to see what these prospects really needed.

The advertisements which the water company runs in the Indianapolis papers are educational and talk about the modernizing of property with sanitary plumbing, a higher standard of living, running water in the home, etc. They all end with the phrase "Consult your plumber" and point out that Indianapolis plumbers will sell fixtures on the partial payment plan.

Baltimore's Pier System Worthwhile Revenue Producer

Baltimore's great system of piers, known as Nos. 1, 2, 3, 4, 5 and 6 Pratt Street, are producing a worthwhile revenue, according to the Municipal Journal.

Under the supervision of the City Comptroller the city leases space on these piers at 42 cents a square foot per year. The total surface of the combined piers is 1,185,379 sq. ft. The combined length of all these piers, if placed end to end, would be 6,888 ft.

Prior to the great fire of 1904 the city owned but little wharf property of importance. The fire made it possible to acquire all of the burnt district fronting on the harbor (about 4,000 linear feet), and under the Six Million Dollar Loan the city purchased the property and removed all buildings streets, etc., and laid out a system of public wharves and docks south from Pratt Street, which has been made 120 ft. wide, with many streets running into same, also widened and improved. The public wharves and docks situated in the upper harbor are intended for coastwise, bay trade and market boats. The market boats come in at Pier No. 4, Pratt Street, or Long Dock, as it is commonly known, which is at the foot of Market Place and within a stone's throw of the Wholesale and Fish Markets.

Tenants occupy most of the space on these piers, but that part which is not leased is used for storage purposes for lumber, etc. In one year the wholesale lumber merchants handled over 70,000,000 ft. of lumber on the Municipal Piers and paid the city about $75,000 for this privilege alone.

Service Connections

Placed in Advance of Street Improvements

SOME interesting information regarding the experiences of Indiana cities in constructing service connections before a permanent pavement is laid, was brought out at a meeting last spring at the Indiana Section of the American Water Works Association. The notes following are taken from the November Journal of the Association.

Muncie.—We have not been very successful in our city in having the cooperation of the board of public works in helping us to complete service connections before permanent paving is done. Where it is necessary, we put these services in and try to collect from the property owner. In most cases we can collect, but there are a good many cases where we cannot. Where we collect from the property owner we put an account in our ledger and keep under this account the costs of the material, labor, etc., as a credit on our ledger. When the service is put in he is permitted to use that much water before he is made any charge. That seems to be the only way we can do it, but it is awfully difficult to do. The connections must be put in before the streets are paved and if the property owner does not pay it, it is handled as a lien and collected just as any other lien is collected.

Evansville.—We install services and charge the immediate property owner for these services. If they do not pay it, we add it to the tax assessments.

Kokomo.—We have a city ordinance providing if the city is to put in the paving we make a survey and furnish the city engineer and contractor who has the work a list of the lot numbers and sizes of service we think should go to the lot. This amount of money is added to the assessment roll. The contractor advances the money to us before he starts to work. The contractor pays us for the estimated amount of services and this is added to the assessment. When the service is used we refund to the consumer. We collect for ½ in. service, $25.00 and for ¾ in. $32.00. We carry these funds under an account listed as "Service Deposit" in the ledger, we can take off a trial balance at any time.

Evansville.—On non-improved streets we charge $10.00 for the service. This amount is charged to the contractor who puts in the street. He takes it over to the county or city clerk who takes it to the Board of Works. They add a charge of $1.00 to the charge we made and add it to the assessment roll. The charge then corresponds with our books.

Do you refund that to the consumer when he takes service?

Evansville. — No. For improved streets we charge $25.00, brick streets $15.00 and for unimproved dirt streets, $15.00.

Richmond.—For a number of years through the cooperation of the Board of Works, when a permanent improvement is to be made, the city engineer notifies the property owner that gas, sewer, and water must be installed. He indicates where the water taps are to be made and notifies the water company where the services are to be located. The record is sent to the Board of Works, added to the list of assessments of the property owners, in the city treasurer's account, and the water company is reimbursed for the actual cost of services. The water company has to lay all services to the curb, except in this case. After the owner makes application for water, the company refunds the cost of those services to the curb. There is no revenue until the service becomes revenue-producing. We refund the actual cost at the time it is put into service.

Evansville.—When you figure actual expense of refunding you are figuring overhead in general office, etc. Can you figure overhead in ledger and journal entries and construction? I do not see how you can figure insurance and time of making ledger entries, etc.

Richmond.—We add 10 per cent to the cost.

Lafayette.—We have an ordinance to cover this matter. We proceed in this manner: We require on applications for water the advance sum of $30.00. This $30.00 becomes a rebate in water rent until it is used up. We proceed in this manner on hard surfaced streets. We place the regular ⅝ in. service to the edge of the lot. We notify that the service has been put in. We give a description of the service and when the property becomes a consumer, they get credit for water rent to the amount of $30.00. We get along very nicely. Most of them are glad to know they have water when they come to sell the lot. If it is not paid we certify it to the Board of Works and in that way to the city treasurer, showing a lien on this property. It becomes a refund in watre rent later if it is not put in use for ten or twenty years. We could charge 6 per cent on these deferred payments, but we have not carried this out yet. The Acts of 1927 require platted ground to put in these services.

Evansville.—We charge $10.00 a service for unimproved dirt streets, $15.00 brick improvement, and $25.00 for asphalt before these services are installed. We do the best we can. We send postal cards, as a great many of these people live out of town.

Lafayette.—We do not call it charge; an advance is what it really is. We send a letter stating that it is payable by a certain time. If they fail to pay it, we certify it to the Board of Works, Controller and City Treasurer. When they come to pay the taxes the Treasurer informs them that water has been put in and that we require the payment of $30.00 from each applicant. We go ahead and do this and notify the owner it has been done. Very few unpaid services are put in on account of the hard paved streets.

Evansville.—If you would make a charge of so much to each property owner regardless of whether on the near or far side of the street for each service installed on the property, you would eliminate a great deal of trouble.

Richmond.—A uniform charge would be very desirable. That matter was taken up before the Commission. It seemed fair to make the same charge to the property owner on either side of the street. They said, "No." They said "you must make it the actual cost. The short side of the street has the advantage."

Evansville.—It would hardly be fair, if you spent $8.00 for a short service, to charge $18.00. I think you should bear that cost. If you buy a lot, you do not go down to the Board of Works to find out on which side of the street, far or near, the gas or water main is. Why should not the owners on either side of the street pay the same price?

Columbia City.—We are going ahead and making service taps, putting in the work and material at cost. We give the property owner 30 to 60 days to pay. We have never had any trouble in collecting our accounts. We make no refund whatever. It is a publicly owned plant. The property owner takes care of his service from the main to the curb and into the house. Everything is satisfactory. The water company, municipal or private, should run the service to the curb free to the consumer. They would have to rebate to every consumer from the main line to the curb, the cost of the labor and material. Of course, it is more on the long side of the street for labor and material. We do not aim to make any profit. We charge just what it costs. If we pay labor 40 ct. an hour, we charge the consumer 40 ct. an hour, and material the same. We keep that cost down as low as possible and we have no trouble.

Richmond.—Our company does not consider the 10 per cent profit. The 10 per cent is to cover insurance, superintendence, and legitimate additions to the cost. It is not a profit. It is incidental and intangible.

City Swimming Pools of Baltimore, Md.

According to a recently issued report of the Board of Park Commissioners of Baltimore, Md., the average yearly receipts of the Municipal swimming pools for the period of 1918-1928 amounted to $29,830. The investment in swimming pools is $900,000, not including the recently opened bathing beach at Fort Smallwood Park. The total number of patrons in 1928 was 498,665 and the average daily attendance at six pools was 6,472. The average daily cost of operation of the pools was $419.77 and the average daily reecipts were $567.86.

What's the Construction Outlook in the Municipal Field for 1929

Symposium of Opinions from Consulting Engineers Indicate an Active Season

Municipal Bridges for 1929

THE coming year promises to be one of unusual activity in the field of municipal bridges. The continued growth in motor vehicle traffic is rendering existing crossing facilities inadequate, and new bridges are being demanded to supersede ferries or to supplement existing spans. The newer structures are generally of larger magnitude to meet the requirements of greater traffic capacity and more generous navigation clearances. In many instances municipalities are now demanding long-span high-level bridges where low-level movable spans have heretofore prevailed; the desire to avoid traffic interruptions and delays, rather than maritime requirements, is the governing motive. Individual bridges of today represent much larger investments than those of the past. Everything in this field of construction is now being done on a larger scale. The recent rapid development of privately built toll bridges to meet the needs of vehicular traffic has apparently stimulated municipal interest and activity in bridge construction. The entire nation has become "bridge-minded."

In all parts of the country, cities and counties are voting large bond issues or are otherwise projecting bridge undertakings of magnitude. In the Northwest, large bridges have been voted or are being promoted in Portland, Seattle, and Tacoma. San Francisco is seeking authority to build a structure of unusual magnitude across the bay to Oakland or Alameda. In the Middle West, large municipal bridge projects are in various stages of advancement in Louisville, Cleveland and Toledo. In the East, municipal bridge projects of magnitude are under study or construction at New York, Providence, Norfolk, Knoxville, and Albany.

In the newer bridges planned for municipalities, more consideration is being paid to artistic development of the design. The technical problems of stresses and strains have long ago been surmounted, and the designers are freer to devote their attention to studies of form and proportions. Pleasing appearance is sought, not by extraneous embellishments but by development of the most effective lines and harmonious proportions in the essential elements of the structure.

American cities are now voting many millions of dollars annually for new bridges. These are being planned on the basis of comprehensive city planning studies and traffic surveys. They are being built to afford needed traffic outlets, to by-pass and relieve congestion, and to develop new areas of population or industry. The public takes a wholesome interest and pride in each project as an expression of the spirit of enterprise and achievement of the community.

New York, N. Y.

Prospects Bright in Chicago District

Prospects for municipal construction under our supervision for 1929 are healthy. Underground improvements probably will approximate the 1928 volume; while that of paving and street lighting may exceed it. Our 1929 construction in the Chicago Metropolitan district will probably reach $5,000,000; in the Kentucky district $1,000,000; in the Central Wisconsin district, $1,000,000 and in the St. Louis district $1,500,000. A large portion of the work in the Chicago, St. Louis and Central Wisconsin districts consist of water filtration and sewage disposal plants.

CONSOER, OLDER & QUINLAN,
205 West Wacker Drive,
Chicago, Illinois.

Future Prospects Attractive in New York

The prospect for engineering work in the municipal field for 1929 appears unusually attractive. The writer as consulting engineer in conjunction with Whitman, Requardt & Smith, Engineers, is engaged in the construction of a new gravity water supply system for the city of Albany, at an estimated cost of about $9,000,000. The village of Herkimer, N. Y., has just let contract for the construction of a new gravity water supply, from plans prepared by the writer some years ago.

Various other projects are in hand or appearing on the horizon and the indications are that continued prosperity and industrial growth will demand and provide the necessary means for municipal improvements, particularly in connection with water supply and sewage disposal.

ROBERT E. HORTON,
Voorheesville,
Albany County, N. Y.

Expects Sanitary Refuse Disposal Projects

The prospectus of work in the municipal field seems fairly bright in northern New Jersey. The rapid progress of the construction of the Hudson River bridge has indeed hastened the highway building program in Bergen and adjoining counties. Scientifically planned developments like the "Motorage" city of Radburn, between Hackensack and Paterson, progressive townships Teaneck, Englewood, etc., are bound to keep pace with the rapid growth of the communities as far as sewer and street programs are concerned. There is all reason to believe that Teterboro and other airports will see vast improvements in the course of the coming year.

The Bergen County Chamber of Commerce, local chambers, businessmen's associations, service clubs and civic bodies are keenly interested in these questions as well as in the development of a state wide park system.

I have done, personally, a good bit of missionary work during the last few years spreading the gospel of sanitary refuse collection and disposal in properly designed and operated incinerators. Various communities of this district are talking incinerators, several have appropriations and it is to be hoped that the new year will see several incinerator projects materialize.

JOHN H. LIEBAU, R. A.,
328 Main St.,
Hackensack, N. J.

Big Improvements in Offing

A great many projects of magnitude, particularly with reference to sewerage systems, sewage treatment works, water works, and extensive drainage programs, have been investigated, reported on, and designed during the past year.

While there is a difference of opinion concerning the effect of a presidential year on business generally, I am convinced that engineering projects proposed for execution under political or semi-political direction have been effected. In some cases the contracts are awarded for whatever may appear advantageous to the public. In other instances a retarding effect is produced; presumably with the thought that agitation for or against might be considered detrimental to public policy.

In reviewing my practice and taking into consideration the prepared data on

extensive engineering works, I can, without any great degree of optimism, predict that the coming year will see an active construction program started. Many changes are taking place in the Metropolitan zone and huge engineering undertakings are under way. The compelling factor expediting these huge projects is—dire necessary.

Many of the contracts with which I am intimately associated are waiting the starting or completion of bridges, tunnels, and transportation facilities; and, reflecting on the development of the past year, it appears that 1929 will usher in an awakening for many of the apparently dormant projects.

THOMAS F. BOWE,
110 Williams St.,
New York City.

Prospects Bright for Hydraulic Construction

The outlook for 1929 is very encouraging in view of the fact that we have, as a nucleus, at the present time the completion of the plans and specifications for an additional water works station for the City of Erie to include an intake line from the lake, a low service pumping station, a filtration plant, a high service pumping station and connecting force mains designed for an ultimate capacity of 48 million gallons per day, of which 16 million gallons will be installed in 1929 at a cost of approximately $1,500,000. This will give the City of Erie, upon completion of these works, a total capacity of 48 million gallons per day, and ultimately 80 m. g. d. In addition to the water works, a sewage disposal plant has been designed for the City of Erie, the construction of which will proceed early in 1929. This plant was designed for a capacity of 40 million gallons per day. The project will include also the main interceptor leading to the sewage disposal plant and the construction of an open concrete channel for Mill Creek which will be straightened out through the site of the sewage disposal plant. The great majority of the intercepting sewers and overflow works was completed recently from plans prepared in this office. The cost of the interceptors, so far completed, has been in excess of $1,000,000.

Nineteen twenty-nine will see the completion of an extensive and comprehensive program of water works development designed by this firm for the City of Nashville, Tenn., when the 28 m. g. d. filtration plant of the city will go into operation. Likewise, the new water works of the City of Bowling Green, Kentucky and sewage disposal plant and sewerage system involving more than 20 miles of sewers for the City of New Lexington, Ohio; the softening plant at Fostoria; the sewage disposal plant for the Torrance State Hospital at Torrance, Pa.; the new water works and softening plant of the Borough of Sewickley; additions to the water works and electric power plant of the Borough of Etna, Pa.; the concrete arch impounding dam of the City of Norton, Virginia, and the reservoir improvements at Newport, Kentucky, will be completed in 1929. A new pumping station and filtration plant for the City of Lockport, N. Y., costing approximately $500,000, will be started early in 1929 as contracts for this work have already been let. Contracts for a garbage incinerating plant and substantial additions to the sewage disposal plant of the City of Greenville, Pa., will be let early in 1929 from plans already completed.

In addition to the above there are a number of other projects, one of considerable size and the rest somewhat smaller, which are in the course of preliminary studies and it is possible that the greater portion of this work will proceed to construction in 1929.

In general, the outlook for 1929 in our field and in general municipal improvements, such as roads, bridges, public institutions, etc., is very promising and we are rather optimistic.

THE J. N. CHESTER ENGINEERS,
Clark Building,
Pittsburgh, Pa.

Outlook for Municipal Construction Work

Due to a general slump of business in 1927, the percentage of taxes collected in the smaller municipalities surrounding Detroit was quite small. As a consequence the amount of municipal construction was smaller than usual, however, factories have been running full blast in 1928 and the tax payer has more money and will be more inclined to request improvements for 1929.

It is my belief therefore that there will be a considerable volume of sewer and water construction done in those villages that require such improvements with an increase in the amount of paving laid where sewers and water have already been installed.

HARRY L. HUDSON,
Broadway Exchange Bldg.,
Detroit, Mich.

Ohio District Has Good Outlook

The outlook for work in the municipal field for 1929 in this section of the country looks to be very good.

Many Ohio municipalities voted favorably on bond issues at the past November election and considerable work in the sewerage and water works fields undoubtedly will be started this coming year.

H. P. JONES & COMPANY,
1601-8 Second National Bank Bldg.,
Toledo, Ohio.

Parkway Improvements Along Hudson

In Westchester County, New York, several important projects under construction will be completed, work on new ones started and important projects for the future developed during the year 1929. Some of these in the eastern section of the county are the new Saw Mill River parkway, Cross County parkway, repavement and improvement of existing highways and streets and elimination of railroad grade crossings. New projects for which surveys, plans and financing are to be developed are the Hudson Riverside driveway, sewers and disposal plants.

The Westchester County Parkway Commission's construction program for 1929 includes the Saw Mill River parkway and the Cross County parkway. The Saw Mill River parkway is in a valley about a mile from and parallel to the Hudson River, and to extend from Yonkers about 7.5 miles northward to Elmsford; it will handle considerable north and south traffic of this section of the county. This is to be opened to traffic as far as Ardsley in the fall of 1929. Most of the grading, drainage and bridges have been completed, the remaining work consists of paving a 40-ft. driveway, landscape, grading, planting, lighting and paths from Tuckahoe Road, Yonkers, through Hastings-on-Hudson to Ardsley a distance of 4.1 miles at an estimated cost of $896,000, and grading, drainage and bridges for a continuation of the driveway from Ardsley to Elmsford a distance of 3.4 miles at an estimated cost of $594,000. The Cross County parkway work will include grading, drainage and bridges from Valentine Avenue, Yonkers, eastward to the recently opened Hutchinson River Parkway at California Park, a distance of 4.1 miles at an estimated cost of $1,692,000.

The Ravensdale-Jackson Avenue improvement in Hastings-on-Hudson and the Town of Greenburgh will be started in the spring. The work will include the elimination of the railroad grade crossing of the New York Central Railroad, Putnam Division at Ravensdale Road and the repaving and improvement of Ravensdale road and Jackson Avenue from Farragut Avenue eastward, across Saw Mill River parkway to Central Avenue. This is a cross county highway the improvement of which is essential for the execution of prospective local developments and needed in this part of the county. The grade crossing elimination is to be completed by the fall which will permit progress to be made upon the county improvement of the highway.

Warburton Avenue-Broadway improvement in Hastings-on-Hudson. Warburton Avenue is west of and parallel to Broadway, connecting to Broadway at the northern end and

when improved will relieve traffic congestion of Broadway. It is more direct with fewer hills and affords attractive views of the Hudson River for miles and of the Palisades on the opposite of the river. The survey has been made and repaving work is to begin in the spring starting at the Yonkers line. The type of pavement is to be decided by joint conference of village and county authorities.

The proposed Hudson Riverside driveway has been surveyed from Van Cortlandt Park, New York, to Kingsland Point and the Westchester County Board of Supervisors announced an estimated cost of the project as $34,000,000. The communities along the Hudson are endorsing this project and endeavoring to arrive at a solution of the financial problem. State aid has been discussed for the financing, being a large amount for the county to handle and the highway would be more of the nature of a state highway.

In the villages of Dobbs Ferry and Hastings extensive programs of street improvements have been carried out through 1928 and will be continued in 1929. Problems confronting the municipalities in the eastern area of the county are the early solution of the matters of sewers and disposal plants. With the continuously increasing population the present sewer systems will soon become inadequate necessitating intelligent planning now, for the immediate as well as distant future. A trunk sewer in the Saw Mill River valley, a disposal plant in the vicinity of Yonkers and an incinerator in the Town of Greenburg are projects for which plans and financing are being considered. The elimination of all telegraph and lighing poles from the main streets of Dobbs Ferry and other villages is contemplated also improvement in illumination and ornamental street lighting fixtures, including Dobbs Ferry and Hastings-on-Hudson. The Edwin Gould playground in Dobbs Ferry will be completed in 1929.

The crossing of parkways and highways with intersecting thoroughfares are generally planned and constructed on new developments to avoid crossings on the same grade by means of bridges and tunnels, as a permanent means of facilitating traffic and insuring safety at a minimum of maintenance cost. However some existing parkways and highways and also new projects have crossings at same grade which might have been easily avoided originally and plans may be developed for the elimination of some of these highway grade crossings. These grade crossings retard speed of traffic, require maintenance and operation of traffic control signals and constant supervision of traffic officers and, notwithstanding precautions for safety, they are a continuous hazard. Who should stand the expense of the maintenance of traffic control at such crossings is a frequent controversy. More attention and effort to avoid and eliminate highway grade crossings as well as railroad grade crossings should be made. This can be accomplished during original planning and construction with less expense than after completion of construction.

There are several railroad grade crossings of the New York Central Railroad, Putnam Division, in the Saw Mill River valley. Some of these are to be eliminated and the elimination of others have been considered. A bridge over the tracks at Nepperhan Road, Yonkers, is under construction eliminating this grade crossing and is to be completed in the spring and the bridge at Ravensdale to be completed in the fall will eliminate that one. It is expected that plans for elimination at other places will be consummated to remove the constant menace of such crossings.

Highway construction work in Westchester County will amount to about $8,000,000. In 1929 practically all projects of which have been officially approved; this includes State, County and Town work. Eight railroad grade crossings are included in the 1929 program and the construction cost of these structures may be about $2,000,000.

H. W. SCHARF,
83 Cliff St.,
Hastings-on-Hudson, N. Y.

Buffalo Vicinity to Compare Favorably with 1928

Street paving for the coming year, of which the largest percentage will be sheet asphalt on concrete base, will about equal that of 1928. The completion of bridges over Buffalo River and Cazenovia Creek will open the important thoroughfare of Bailey Ave. to traffic for its entire length. Just outside of the city line, the construction of a few short gaps of road will complete the outer loop of the Greater Motorways System, providing a detour to points south, east and north of the city without entering the city at any point. The new Southwestern Boulevard, about thirty miles long, will be about half finished. This is a 40-ft. road over entirely new right of way and parallels the present Lake Shore Highway about two miles south. Where it crosses Eighteen Mile Creek, the largest concrete arch highway bridge in this part of the state is being built.

Half a mile of Outer Harbor concrete dock wall is planned, which will enable the city to finish the grading for a large waterfront park. The remaining six hundred feet of concrete bulkhead required to complete the Niagara River side of Bird Island pier also is scheduled for construction. Dredging of Erie Basin will continue.

The fourteen hundred feet of Cornelius Creek drain, a 7 ft. x 10 ft. reinforced concrete overflow sewer, will be finished. Preliminary studies for a sewage disposal system for the entire city are well under way.

The new $14,000,000 Curtiss Street passenger terminal of the New York Central Railroad will be ready to use about May 1st. Plans for the new downtown passenger station of the same railroad will be ready so that work on this project should start soon after the Curtiss Street station is opened. Under the jurisdiction of the Grade Crossing and Terminal Commission, work on the Amherst-Austin Street grade crossing elimination, at a cost of about $3,000,000 will be started in a short time.

Bids will be called for on the new $6,000,000 city hall early in 1929 and work on the new State Teachers' College buildings and the state office building will also start early in the coming year.

CUTHBERT E. REEVES,
Liberty Bank Bldg.,
Buffalo, N. Y.

Expect Average Year

It is extremely difficult to make a reasonable estimate of the outlook for municipal engineering work likely to be undertaken in 1929 other than that handled directly by city engineers. From present indications, however, it is our impression that the amount of work which we are likely to handle will approximate the average of the past 4 or 5 years. It does not appear likely that there will be abnormal activity nor that there will be an especially small amount of work to be handled. It is our impression that 1929 may probably be expected to be an average year.

METCALF & EDDY,
Statler Bldg.,
Boston, Mass.

Southern District Prospects Optimistic

The indications are that there will be more than an average amount of municipal work such as waterworks, sewers, sewage disposal plants and street paving, in Oklahoma and Texas in 1929. A great many municipalities have mapped out programs for these improvements for which bonds should be voted or funds provided early in the year. It is our opinion that 1929 will show greater progress than this year.

BENHAM ENGINEERING CO.,
Perrine Building,
Oklahoma City, Okla.

Predicts Good Year in 1929

Indications are that 1929 will be a good construction year in water works and sewerage projects.

BARKER & WHEELER,
36 State Street,
Albany, N. Y.

Hydraulic Construction Expected to Be Active

Judging from work under way in our office, which is likely to go into construction the coming year, we are of the opinion that water supply, sewerage and sewage disposal for 1929 will be very active.

More large projects are now in prospect for starting construction next year than in any prior year. Construction prices apparently will be somewhat higher than in the last year or two.

As we specialize mainly in water supply, sewerage, sewage disposal and flood relief, we are only competent to express our opinion along those lines and those we believe will be active.

ALVORD, BURDICK & HOWSON,
8 So. Dearborn St.,
Chicago, Ill.

Immediate Prospects Not So Good

There does not appear to be a great deal of work in immediate prospect, but for municipal work there is needed construction in connection both with the city sewage system and its water works, the water works being more in the nature of extensions rather than improvements to filter plants and pumping stations. Also, it is expected that work will be started during the coming year on a bridge across the Delaware River connecting Burlington and Bristol, but this is a private enterprise though it involves street changes as well as the construction of the bridge itself.

CONRAD & BUSBY,
321 High Street,
Burlington, N. J.

Considers Prospects Good

An examination of the prospects in the municipal field, for engineering construction, seems to indicate that 1929 should prove a good average year. The slump in real estate activities together with a weak market for municipal bonds during 1928 resulted in the postponement and withdrawal of a considerable volume of work. National and local elections also have had their effect. However, with the election over and general business in excellent condition in the Chicago district, we are looking forward to an increase over last year's business.

KELKER, DE LEUW & CO.,
11 West Washington St.,
Chicago, Ill.

Patzig Expects Greater Activity

Municipal work in this territory for 1929 at this particular time looks normal. It has repeatedly been our experience that judging future conditions at this time of the year is difficult to do. Present rumors, however, indicate a little greater activity towards municipal construction than they did a year ago. Our business and agricultural conditions are better, so one feels justified in expecting a greater amount of construction work.

PATZIG TESTING LABORATORIES,
210 Eleventh St., Des Moines, Ia.

Mulholland Retires

Editorial in Nov. 15 Los Angeles Times.

Los Angeles owes more to William Mulholland, whose retirement as chief engineer of the Water Bureau has just been announced, than to any other one individual who has ever been associated with its service. For fifty years continuously he has labored to perfect the Los Angeles water system, and for twenty-six years has been its chief engineer. He will be long remembered as the builder of the Los Angeles Aqueduct, the boldest and most spectacular engineering work ever attempted by an American city, as well as one of the most difficult.

During his term of service the Los Angeles water system from a few miles of pipes valued at most at $100,000 has grown to a system of 3,200 miles of conduit worth at least $100,000,000, and supplying 285,000 homes, buildings and factories over an area of 440 square miles. The tribute paid to him by Commissioner Del Valle may well be quoted in part:

"He has ever regarded the duty of keeping the people supplied with water as sacred and inviolable. Many a time has this city been saved from actual shortage by the sleepless vigilance of this one man. Domestic use has been maintained; municipal needs have been met, and the public health, dependent at all times upon a pure and potable water supply, has been conserved.

"It may be asserted without fear of successful contradiction that no engineering achievement in this country within the past half-century has exceeded in difficulty or merit that of William Mulholland in keeping the water supply of this city, in its rapid growth and development, up to the requirements of its inhabitants.

"Despite his years and long service, he is still a vigorous and outstanding figure in the community, strong in the affection and esteem of his fellow-citizens. No ill fortune has been sufficient to shake the confidence of the people in this good and faithful servant."

Mr. Mulholland leaves office upon the eve of a still more difficult and costly achievement, the Colorado River aqueduct, but not without having laid a firm foundation upon which his successors can build. The preliminary planning of this great enterprise has been done under his watchful eye, and the city has in his probable successor, Assistant Chief Engineer Van Norman, a man of proved capacity upon whom it may rely to solve the further problems that will arise. Van Norman has had twenty years of service in the Water Department and was a division chief in the aqueduct work. Loaned to the city a few years ago to construct the outfall sewer, he built it in record time and at a saving of $5,000,000 from its estimated cost.

So that if the city suffers the loss of a tried and trusted adviser in Mr. Mulholland's retireemnt, at least he leaves to take up his work a man trained in his own school of rugged honesty and spirit of service to the community. The Water Department has, it is understood, a tentative plan of retaining Mr. Mulholland in an advisory capacity, and it is to be hoped that he can be persuaded to accept such a relationship.

It is difficult to imagine the Water Department without William Mulholland.

Transactions of the Eighth Annual Conference of State Sanitary Engineers, 1927

Public Health Bulletin No. 183, recently released, contains the transactions of the Eighth Annual Conference of State Sanitary Engineers. A number of committee reports in this publication are of general interest. The report of the Joint Committee of the Conference and the American Public Health Association setting forth the final standards for swimming pools and bathing places will have widespread application and should prove to be very helpful to all persons interested in the design, operation, and sanitation of swimming pools. The report of the committee on sewage treatment gives an interesting résumé of the progress being made in Ohio to obtain careful and scientific operation of sewage-treatment plants.

New England City Managers Organize Association.—City managers of Connecticut, Maine, Massachusetts, and Vermont have organized the New England City Managers' Association, to be composed of city and town managers in those four states. The following officers were elected at the first meeting:

President — C. A. Bingham, city manager, Norwood, Massachusetts, and formerly manager of West Palm Beach, Florida.

Vice-president—James E. Barlowe, city manager, Portland, Maine.

Secretary—Roy M. Wilcomb, city manager, Springfield, Vermont.

This association will hold quarterly meetings each year, one in each of the states.

Methods of Sludge Disposal for Small Sewage Plants

Seven Ways of Preventing Sludge Accumulation at Plants

By FRANK BACHMANN
Sanitary Engineer, The Dorr Co., Chicago, Ill.

THIS discussion deals with the disposal of sludge from septic tanks, Imhoff tanks and separate sludge digestion tanks which are in common use throughout the country.

Methods of Disposal.—The following methods of disposal of digested sludge from all types of tanks are in common use:

1. Discharge into stream during flood flows.
2. Lagoons.
3. Filling in low lands.
4. Direct onto land and ploughed in.
5. Dried on prepared sand beds.
6. Dried sludge used as fill.
7. Dried sludge used as fertilizer.

The first five methods refer to wet sludge as discharged from the tanks and the last two to the disposal of air dried sludge.

Discharge into Streams. — Many plants both large and small make use of streams during flood conditions to dispose of their sludge. This procedure is usually not approved by the state board of health but there are instances where no harm is done by this method, especially where the streams are large and the sludge is discharged at the proper time. In most cases. however, evidence of sludge along banks of stream, on vegetation and deposits in the stream itself are noticeable for some time after the discharge of the sludge. As a general practice this method of disposing of sludge is condemned as being unfair to the inhabitants below and in its unreliability because of the uncertainty of the duration of flood conditions. This method is used more in connection with septic tanks which are pumped clean periodically than with any other type of tank, although the sludge from a few Imhoff tank installations is disposed of in this manner.

Much has been written on the disposal of sludge from the larger sewage plants throughout the country where technical supervision is available but little has been said of this problem for the smaller plants. In Ohio, for instance, 80 per cent of the sewage plants serve populations of less than 7,500 people and this percentage is, no doubt, exceeded in some of the western states. The disposal of sludge from the smaller plants is, therefore, of interest to a large number of city officials and operators, and we accordingly are reprinting below an interesting paper on this subject which was presented last November at the Iowa Sewage Treatment Conference.

Along the seaboard it is quite customary to pump the sludge into the ocean during winter months when there is no bathing. Reports indicate that no harm results with this procedure.

Lagooning Sewage.—Lagooning of sludge is not common in the smaller plants. Lagoons, where used, consist of natural or artificial holes in the ground and are usually in sets of two or more for flexibility. Lagoons are from 3 to 10 ft. deep and sludge is run into them until they fill up, after which the sludge is allowed to drain and then is hauled away. Lagoons serve their purpose satisfactorily if they receive a well digested sludge but with a raw or partially digested sludge they usually smell badly. Aside from an odor nuisance lagoons are a source of mosquito and fly breeding. There are very few lagoons being installed today for disposal of sludge because of the objections mentioned.

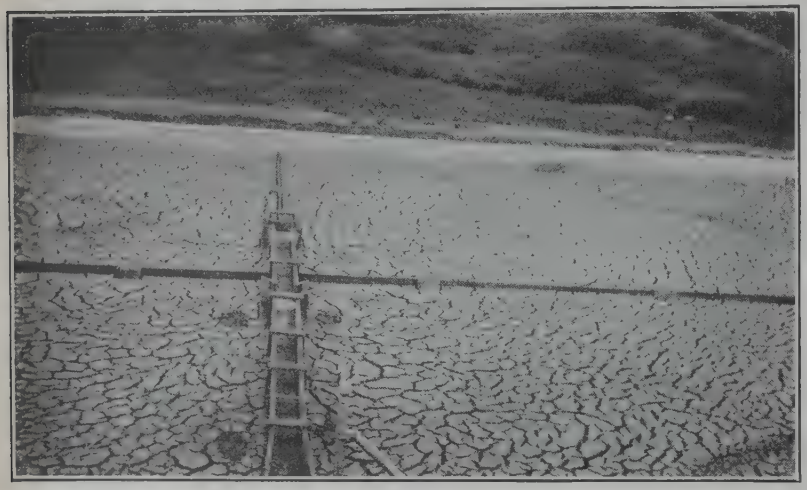
Filling in Low Land.—Where low land is available sludge has been disposed of with satisfactory results by using it to fill in this low land. This is usually only a temporary expedient as other methods must be used when the fill is completed.

Disposal into Land and Plowing In. —Sludge is as a rule disposed of during the summer months and where farm land is available sludge is disposed of by discharging directly on land and after the sludge dries it is ploughed in. This procedure is followed successfully at a number of small plants and has been entirely successful at the large plant at Canton, O. Sludge is usually taken from the tanks during the dry summer months of the year when land will absorb the water readily. This method is in quite common use in the south and on the West Coast where the water in the sludge has a distinct value to crops in addition to the fertilizer value of the sludge. With a well digested sludge, disposal is without nuisance and the fertilizing value of this material will surprise the most skeptical farmer. This method has not been given the credit it deserves and in locations where farm lands are adjacent to the plant it is an economical and practical solution for the sludge disposal problem. Common sense should prevail in distributing the sludge over the land. Excessive amounts in spots are certain to give pooling and thereby retard the drying period. The sludge is usually run into a main ditch from which lateral ditches serve the land.

Drying on Prepared Sand Beds.— The more recent Imhoff and separate

Some Examples of Poorly Drained and Unkept Sludge Beds

sludge digestion plants are provided with specially designed sand beds for dewatering the sludge. If there were sand beds constructed for septic tanks, it it usually hard to find them as they are buried in weeds. Sludge is run onto the sand beds from 6 in. to 15 in. deep and with good weather is in a spadable condition in one to two weeks. Experience has shown that it is more practicable to dose the beds more frequently than to attempt to dry too great a depth. About 9 in. is a good depth of sludge on the beds and greater depth over this may delay its drying. The drying time for sludge depends on weather conditions, depth of sludge applied to beds; and, lastly, but of most importance, is the character of the sludge. A poorly digested sludge may not dry for months, whereas, if well digested it should dry in 6 to 14 days. Sludge as discharged onto drying beds contains 90 to 95 per cent water and will dry to 60 per cent moisture and lower. When in a spadable condition, the sludge should be taken off the beds immediately so that it will not be rained upon and get mouldy. If properly digested, the sludge will not give off offensive odors during the drying process. The dried sludge has a slight odor of humus which is not objectionable. The dried sludge can be piled up near the beds until ready for final disposal.



This Shows a Well Drained Sludge Bed at Hartford, Wis., Also a Good Sludge as Indicated by Its Small Cracks

Dried Sludge Used as a Fill.—The two outstanding methods of disposing of the dried sludge are by using it to fill in waste land and its use as fertilizer. Many plants pile up the sludge near the plant to the detriment of the appearance of the plant grounds. If low ground is not available at the plant provisions should be made to haul the material elsewhere. More attention paid to the appearance of the plant by the operator will result in the town taking an interest in spending money on operation and improvements. Sludge piles around a plant are an eyesore and in this age of progress the value of the sludge as fertilizer is well known and appreciated by the wide-awake farmer who will take all the sludge that is produced without cost to the city.

Dried Sludge as a Fertilizer.—This statement might seem a little optimistic but if an operator cannot induce the farmer to take his sludge, he is considered a poor salesman. We have heard for the past twenty years or more that digested sludge has little fertilizer value. This is true relatively when based on the chemical analysis and compared with commercial fertilizers. Sludge contains valuable ingredients which are not shown by the chemical analysis and which have the effect of loosening the soil and stimulating bacterial growths. Experiments on laboratory scale and in actual practice have shown the great value of this material as fertilizer.

One thing which has made the farmers skeptical is the fact that the material is had for the asking. It is much easier to sell an article of this kind than to give it away. A story comes to mind which illustrates this point, and which is entitled **A Better Method.** "I don't know what to do with this mongrel," moaned Jones, "I've done my best to give him away." "Give him away," protested his up-and-doing wife. "That's no way to get rid of a dog. Ask $20 for him."

Large quantities of dried digested sludge are used for fertilizer in this country, much more than most of us realize. Large cities like Baltimore, Md., Rochester, N. Y., Madison, Wis., Marion, O., and others, have sold the sludge at a nominal price for fertilizer for many years. Hartford, Wis., with about 4,500 people and Kiel, Wis., with 1,600 people use all of their sludge on lawns and shrubbery in the parks in which these plants are located. Many plants have made arrangements with farmers to remove the sludge from the drying beds in payment for the sludge.

Col. E. D. Rich, Director of Bureau of Engineering, Michigan Department of Health, states that the following towns and others in his state are using the sludge as fertilizer: Romeo, pop. 2,500; Grosse Pointe, pop. 3,000; Lapeer, pop. 3,000; Fremont, pop. 2,000; Muskegon Heights, pop. 15,000; and the city of Pontiac with population of 50,000 disposes of its sludge at a price of fifty cents per load. Sludge has been accumulating around this plant for about 3 to 4 years. Offers to give it away failed. The perseverance of the operator and possibly the establishing of a price for the sludge were responsible for interest in this sludge as all of it is sold and none accumulated because of the demand for it.

Many other instances could be cited but the examples given should be convincing evidence to any farmer that this material has value as a fertilizer. From the viewpoint of the operator, his main object is to get it off the sewage plant site even if a revenue is not obtained. A small charge may have its psychological effect in creating a demand for the sludge.

It is hoped that this article will be helpful in pointing out a way to have the sludge removed from the plant sites so as to make it possible to keep the grounds appearing in a respectable condition.

Cincinnati Adopts Uniform Standard Design for Street Casting

All street castings used by the various city departments of Cincinnati hereafter will be purchased under the direction of the city manager. The purpose of this arrangement is to secure a single standard specification for all types of inlets, manhole covers, and gratings, of the best possible design, and of a sufficient strength to carry the heavy loads of modern traffic without breaking, and particularly to do away with the noisy rattling and rocking of manhole covers that has been such a nuisance in Cincinnati and all other cities in the past. These manhole covers will, in future, be machined to an absolute fit so there will no longer be any noisy rattling of these covers.

It is expected, through the co-operation of the Utilities' Companies, to secure in the near future a similar arrangement in regard to their castings used in the streets.

The "Come Back" of Toll Bridges.—On Jan. 1, 1928 there were 233 toll bridges in the United States, 191 of which were privately owned. Since that time construction has been started on 29 new ones, and 163 are proposed. Of the 233 existing the first of the year, 86 were built in the last ten years.

How New York City Use Statistics for Accident Prevention

How Investigation of Accidents Leads Way to Prevention

By PHILIP D. HOYT
Deputy Police Commissioner, New York City

THOSE of us who are responsible for traffic control in New York City know the importance of using facts in deciding upon our traffic program. Traffic counts, speed tests, and other factual data which we obtain, are used almost daily; but no set facts that we obtain are more important than the accident statistics which we use in our plans for traffic control.

The traffic problem is one of many phases. City or regional planning, the study and initiation of engineering projects which will provide additional facilities, is one of them. Regulation or handling of traffic with existing facilities is another. Discussion of the traffic problem too frequently considers one purpose of regulation—the acceleration of traffic, and ignores or minimizes the more important function, the protection of human life. Speeding up traffic is of course an essential object of regulation, but public safety comes first. The primary duty of the police in handling traffic is no different indeed from its duty to protect society against the criminal element. That is why traffic regulation generally lies in the hands of the police.

The complexities of the traffic problem in New York City are increased not merely in proportion to its population, but because of many other factors, some of them peculiar to this city. The geographical barriers which divide and surround the city; the density of population; the height of the buildings; the number of automobiles; the extent of the suburban district—all complicate the situation. Handling traffic safely under such conditions on the city's five thousand miles of streets, is a task calling for the utmost effort.

Accidents Reduced.—Our toll from street accidents is high; yet we feel we are making some progress in our attempt to serve human life by a thorough and systematic study of accidents. Last year, for the first time since the appearance of the automobile, the number of fatalities and injuries to both adults and children resulting from highway accidents in this city, decreased from the preceding year. The fatalities from motor vehicles in this city in 1927 were 17.8 per one hundred thousand of population. The figures of the National Safety Council show that the general rate for the entire country, urban and rural, was 19.6 per hundred thousand, while the urban rate was 22.4.

The most encouraging fact, however, is that since 1923 there has been a steady reduction year after year in fatalities to children of sixteen and under, due to highway accidents in New York City. In 1923 there were 453 children killed; in 1924, 432; in 1925, 422; in 1926, 413, and in 1927, 408. In the first eight months of this year 218 children were killed as compared with 266 during the corresponding period last year, a decrease of 18 per cent. It is not, however, my intention to burden you with figures. Those I have just referred to are sufficient to give you a picture of the accident situation in this city and to show the decided progress in the reduction of accidents. This is due in no small measure, in my opinion, to our use of accident records. It is my purpose in this discussion to tell you something about our system of collecting, classifying and using these records.

Accident Card.—The information relating to each accident involving death or injury comes in the first instance from a report made out by the patrolman on post. A printed card used for this report calls for certain specific information. The principal causes of accidents are specified on this card, so that the patrolman who has occasion to make out the report knows exactly what information we require. On the back of the card is a blank space calling for the details, for purposes of further classification. Our total force of 17,500 policemen is at our service in investigating accidents and making out these reports. One copy of the report or printed card goes to the local police station, in the district where the accident occurred. Another goes to the Information Bureau at Police Headquarters for various uses which will be referred to, and a third goes to the Accident Record Bureau of the Traffic Division, also at Police Headquarters. The Captain of each of the local precincts keeps his own file of these cards and prepares from them a precinct spot map of accidents in the district of which he is in charge. Each Captain is thus able to keep in close touch with the situation in his locality. The cards returned to the Information Bureau are used for a variety of purposes, such, for example, as checking up persons who have been reported missing, and who the cards may show have been removed to a hospital following a highway accident. The cards returned to the Traffic Division are first classified by names alphabetically. Reports are received daily from the Medical Examiner, and these are carefully checked; so that when an accident victim reported as injured later dies, the report may be corrected.

Causes Listed.—Every accident is next listed as to the cause. Seventy different causes are included in this classification. The cause records are the basis of a monthly report. The next classification is according to location. This is made in three ways. First, by a file of streets and avenues; second, by police precincts, and third on spot maps which show the location of all accidents involving death or injury for each of the five boroughs of the city. Further classifications are made as to the hours of accidents and the ages of the victims, divided into several groups. In the case of children sixteen years old or under, several special classifications are made. These are according to ages, hours, school districts and schools.

All these records being merely collected, classified and filed away would be of little value. To avail ourselves, therefore, of this store of information is our next task. It is one to which we have devoted considerable thought in an effort to develop a system that would be of material aid in reducing traffic hazard. The monthly summaries are carefully studied. Our first interest is in the total for the month and the comparative figures for the preceding month and preceding years. Are accidents increasing or decreasing? Are children or adults the victims? What are the principal causes? Are they on main avenues or side streets? What hour do they occur? The answers to these and similar questions are found in the summaries and they give us a general idea of the accident situation in the city.

Locations Studied.—Closer study is made of the localities of accidents. This street has a high record. Is it because of the lack of traffic control, or inadequate regulations? The locality classifications are of particular interest in our planning of traffic control light systems; in fact, they are the basis of our request for appropriations for that purpose. Traffic lights may be provided where policemen may not. By the end of this year some 3,500 intersections in this city will be controlled by traffic lights. It would take about seven thousand policemen to cover these crossings

during the hours when the lights will be in operation, involving an annual cost of more than seventeen million dollars. That does not mean we save that amount by supplementing traffic officers with traffic control lights, but it does mean that traffic lights will provide control at nearly three thousand intersections where otherwise control would be impossible, not only from the standpoint of cost, but because of the difficulty of obtaining and training that number of additional men of the right calibre.

So in planning our traffic light programs, the reports showing just how many persons were killed and injured on each thoroughfare of the city are of the utmost importance. The assignment of the three thousand men detailed to traffic duty in this city and the sixteen hundred others who do special duty in the vicinity of schools, is another task calling for frequent reference to the locality record.

Special Regulations.—In addition to the general regulations which the Police Department makes for the control of traffic here, several hundred special regulations affecting particular localities are made each year. In our consideration of the necessity for such regulations, many of which are requested by residents or civic organizations in the various neighborhoods, the locality accident records are of great use. These records also aid in the direction of the activities of the police in enforcement. They often tell us where more attention should be given to speeders, or that drivers are not observing strictly the regulations covering turns, right of way, or other rules.

Investigation Squad.—In order to go more deeply into accidents involving deaths in this city, the Traffic Division has recently inaugurated a system providing for a more detailed investigation of such accidents. Every death now occurring in the city as the result of a highway accident is investigated by a special squad, operating from Police Headquarters. This squad is composed of experienced traffic men who work in uniform. The work is so distributed that the investigator can give a full day to each fatal accident. Although the information received from the patrolman on post is quite complete, there are frequently conditions at the points where accidents occur which the ordinary policeman does not feel the responsibility to investigate and make the basis of recommendations to his superior. The members of this special squad, being few in number, know exactly what information is required, and their business is to make recommendations to improve traffic conditions at that point. The investigator visits the scene of the accident at the same hour of the day when it occurred. This enables him to take into account all conditions at that particular time, such, for example, as the volume of traffic, street lighting, or many other factors. The investigators are all draftsmen, and their report includes a diagram of the locality, showing all the physical conditions and the position of the vehicles or pedestrians figuring in the accident. Specific information covering several points is required in the report—whether there was a traffic post or a traffic light at the point involved; the street lighting condition; any special traffic regulation, such as one-way street; and the condition of the pavement. These reports are taken up in conference with the patrolman who wrote them, and there is a thorough discussion of conditions at each point, for each fatality, so that we may get an answer in each case to the question whether anything possible can be done to improve conditions.

Jurisdiction.—Many of these recommendations naturally come within the jurisdiction of the Police Department. Attention may be called to a crossing where traffic lights or traffic policemen should be provided, warning lights indicating dead end street, for example, or various other traffic regulations of a cautionary nature may be necessary; regulations such as one-way streets may be advisable. The investigator's visit may result in the discovery that particular attention to enforcement should be given at this point. White lines to designate pedestrians' crossings may be needed. Many recommendations relate to other departments. Street lighting conditions may be in need of repair or improvement. Repairs to highways or bridges may be necessary. The highway facilities may be inadequate, requiring engineering measures for relief. In some cases the recommendations relate to individuals or private agencies, involving, for example, the routing of vehicles to less congested sections. The investigations frequently disclose facts of interest to the school authorities and their cooperation is sought.

This system of a detailed investigation of fatalities, although comparatively new, and by no means fully developed, has been found to be of the greatest assistance to us in improving traffic conditions.

So you see there is hardly a step in our traffic program, whether it relates to the assignment of personal investigators, the placing of traffic equipment, or the use of our broad regulatory powers, that is not based upon our accident experience.

In addition to the uses which the Police Department makes of our records, these records are also constantly being supplied to private agencies for use in accident prevention. They are supplied in detail to safety organizations. Organizations interested in the extension of the playgrounds throughout the city obtain them regularly to support their requests for additional recreational facilities.

Safety Education.—One of the most important uses of these records is in connection with the safety education program which the Board of Education is carrying on in this city under the personal supervision of Dr. William J. O'Shea, Superintendent of Education, and also in the parochial schools in the five boroughs of Greater New York. Every month an analysis of accidents involving children of sixteen or under is sent to the school authorities. This analysis stresses the causes of accidents and shows how these accidents vary from month to month. By means of these analyses the school authorities are able to determine what careless practices lead to accidents, and to impress upon the children the need for personal carefulness in these respects. Each of the twenty-seven school district superintendents receives a report for his district. A separate report is prepared showing the number of accidents involving children attending each of the 994 schools in the city; so that each school principal may learn every month whether the accident toll for his school is decreasing or mounting. The value of educational methods in accident prevention cannot be too highly estimated. Our own experience shows that can be done, although thus far we have made only a beginning.

One of the most important uses that can be made of accident statistics, in my opinion, is in safety education. This can best be accomplished through the schools. Safety education in the schools has been greatly developed during the last few years, but its possibilities as a regular part of our school program are only beginning to be realized. Teaching the children how to take care of themselves under present-day traffic conditions is a duty no less important than teaching them reading, writing or arithmetic. Safety instructions, furthermore, can be combined with those and other subjects of the regular curriculum without taking any additional time. Such instructions, in fact, can be so planned that it will stimulate interest in the subjects into which it is incorporated. Education is not my forte, but I feel so strongly on this subject that I cannot refrain from making this reference to it. Personal safety, in my opinion, should be an acknowledged subject of instruction in the schools throughout the country. The importance of such a program is recognized. It remains only for some countrywide educational organization, perhaps some great educational foundation, to get behind this movement, in which great strides have already been made, and develop a systematic, comprehensive plan of safety education, which will be generally accepted as an essential part of the training of our youth. There is no accomplishment that I can think of that would be more worth while.

Some Problems of Water Distribution in New York City

Providing and Maintaining Servicea ble Pressure in Distribution System

By FRED B. NELSON
Assistant Engineer, Dept. of Water Supply, Gas and Electricity, New York City

IN New York City the introduction of the Catskill supply, delivered by gravity at a much higher head than the original Croton and other supplies, made possible extensive improvements of pressure and changes and extensions of service zones and involved many radical changes in distribution. These were local conditions for New York City that have added materially to those problems, common to all cities, of providing adequate distribution to meet the present and prospective demands of sectional development, population increase, etc.

In New York City the Croton supply is delivered by gravity at a head of 133 ft. above sea level at Jerome Park reservoir near the north end of the city, and is carried southward through original aqueduct lines, terminating in Central Park reservoir at 118 ft. above sea level. The Catskill supply is delivered by gravity at 293 ft. above sea level at the north city line and from there is conveyed by 18 miles of deep rock tunnel through the west side of Bronx borough and throughout the elongated island of Manhattan to Brooklyn. This Catskill supply is available for these two boroughs from 18 riser shafts along the line of the tunnel, instead of having to be conveyed southward by trunk lines as with the old Croton system.

Four Service Zones.—To correspond with the topography of the boroughs of Manhattan and the Bronx, the system includes four service zones, supplied under heads suitable for service to the ground elevation included in each. These are: Low service supplied by Croton water under gravity head, intermediate service supplied by pumped Croton, together with Catskill under reduced and regulated head, high service supplied by Catskill gravity or full head of the Catskill tunnel and tower service of Manhattan supplied with Catskill and Croton pumped to about 50 ft. above the available Catskill head for adequately serving the area of highest elevation.

In general the aim has been to utilize the original Croton gravity as fully as possible, reserving Catskill for the higher areas and to save pumping. Unnecessary extension of Catskill service into areas where Croton gravity could be feasibly used by proper changes or reinforcement in the distribution system has been avoided.

This feature was a factor in a recent problem of improving supply to roughly 10 square miles of East Bronx low service area, where a tremendous post-war expansion and building development had rendered the original small supply and distribution mains seriously inadequate in maintaining serviceable pressures under the low Croton gravity head. The need was apparent for a comprehensive hydraulic, or gradient survey, to determine the necessary size and location of needed trunk mains or other changes required, and such a survey was made in the latter part of 1924.

How One Problem Was Handled.—With the center of distribution about 4½ miles from the source and limited by the head of 133 ft. at that source it was considered economically feasible to maintain the area below the 40 ft. contour on the Croton low or gravity service. This would allow a 24-ft. pressure loss in maintaining a minimum of 30 lb. at the 40 ft. or highest elevation.

In determining the location and size of main needed, other less tangible though important factors have to be estimated and used. These gradients were obtained in December, 1924. It was estimated that maximum summer-time consumption in that area, including large summer tent and bungalow colonies, would be 25 per cent greater than in December, giving pressure losses 50 per cent greater than those indicated. Also it was assumed that at the rate of development then under way the consumption of the area might double in five to ten years. Thus the maximum near future consumption might reach 200 per cent of that existing at the time and season of the survey.

The positive data on existing conditions, as presented on the map, clearly indicated by gradient slope, the location and length of needed trunk mains. The size of main was determined by assuming an increase of flow, corresponding with the estimated increase in consumption and selecting a size sufficient to carry such a flow with a loss of head reduced to an amount corresponding with good practice and safely within the limited allowable margin between the supply source and the distribution thus not only to improve the pressure but to maintain it against reasonably distant future demands.

The recommendation for new mains, based on this survey, included 8,000 ft. of 36-in., 11,000 ft. of 30-in. and 19,000 ft. of 20-in. It was estimated that the larger sizes recommended as supplies would include pressures by about 4 to 5 lb. The 20 in. was mainly intended to strengthen the grid for fire supply and to so inter-connect the two larger supply mains that either could serve alone in emergency.

Extending the Bronx Intermediate Service.—Since introduction of Catskill supply the Bronx intermediate service has been greatly extended. Two large north and south trunk mains of the original Croton system, one on the east and one on the west side, have been utilized. The present main source of supply for this service, as previously mentioned, is from Catskill shafts along the pressure tunnel lying west of the service and paralleling those original main arteries. The lack of trunk main capacity in an easterly direction from the tunnel to the original main and centers of distribution has been overcome by hand regulation at the shafts, increasing the day-time pressures and output at these points to that necessary to maintain serviceable pressures at the center of distribution and reducing at the source to avoid excessive night-time pressure increase on the distribution system. The problem here presented did not involve the design of a system of reinforcement to provide serviceable pressures with a very limited head at the source, but rather the determination of size and location of main necessary to so reduce the excessively varying pressure losses as to permit maintenance of fairly uniform pressures on the system with a comparatively constant head at the tunnel. Such a condition is also desirable to permit more automatic regulation to replace hand regulation and to obviate unavoidably serious pressure fluctuations at extremities of the system. In the solution of this problem a gradient survey was made using the same method as previously described. In this case, however, on account of the wide fluctuation due to high pressure losses, extra care had to be exercised to have the gradients obtained under practically simultaneous and normal conditions in order to be comparable in any combination on the final skeleton map. This required some repetition of work and averaging of results, but the variations on repeti-

tions of tests were generally negligible in comparison with the pressure losses determined.

Omitting details, the final map of results showed very flat gradients along those two original north and south trunk mains considered as "headers," but a serious day-time slope or pressure loss between the pressure tunnel and the westerly 48-in. header of 53 ft. determined along the 3,500 ft. of 36-in., constituting one of the main supplies. Also an additional loss of 25 ft. in the 9,000-ft. continuation of this main to the easterly header. The map presented other quite serious additional losses along secondary feeders so that, for example, at one point well within the service area the day-time head was 93 ft. or 40 lb. below that maintained on the supply main at the shaft. As before, the desirable location and necessary length of new mains was quite apparent on the map. The determination of size was made by selecting one whose capacity relative to existing mains, and when working with them, would be such as to bring these excessive pressure losses down to those corresponding with good practice and well-controlled pressures. The mains recommended included 4,000 ft. of 49-in. to eliminate the excessive pressure loss between the tunnel and the westerly 48-in. header and 11,000 ft. of 36-in. from this header to the easterly one to more nearly equalize them.

Such surveys establish the gradients available throughout the existing system, which together with the determined elevation of hydrants, or more roughly the street atlas elevations is used daily on investigations of pressure troubles and by the information desk in answering inquiries as to pressure at specific locations.

Gradient Survey in Manhattan.—In the borough of Manhattan a gradient survey of somewhat different character was made primarily for use in promptly solving these every-day and important problems. Briefly, it consists of a series of east and west gradient profiles of "hydraulic cross-sections" of Manhattain Island taken approximately ten blocks apart from the Battery to Spuyten Duyvil. It includes about 300 hydrants on all of which pressures were taken during the business hours of one day. The pressures were taken with accurate gauges that had been previously tested and calibrated and the corrections applied to the gauge readings in the computation. The nozzle elevations were determined by levels. These hydrant locations, elevations and gradients are listed by streets in geographical order and used daily by the parties on pressure investigations. For office use a street wall map is used, in which the four service zones are shown in color and the gradient of the service at different general locations indicated in large figures that can be read from the distance of the complaint and information desks.

These gradients were taken in September, 1923, under generally normal distribution and weather conditions and have been found very useful as standard reference gradients for solution of the varied problems involving depreciation of service due to increase of consumption and need of reinforcement, or the improvement secured by new installations or changes in distribution. They are useful in locating breaks in mains, open blow-offs, closed valves or restricted circulation and for intelligently advising a complainant as to whether his complaint is justified or due to local trouble under his own control, advising him what pressure to expect on the street main, and whether new or larger plumbing will improve conditions and supply to his top floor. They point promptly to open service boundaries, unwise changes in shaft distribution or regulation, etc. This gradient net work indicates very conspicuously the areas in need of better supply mains and it has been used together with special gradient tests as a basis in solving the problem of determining the size and routes of large trunk mains. Thus about 2,500 ft. of 30-in. steel and 4,500 ft. of 20-in. and 16-in. cast iron main have been laid east and west from one Catskill shaft to flatten the gradient and to relieve the over-load previously carried on the shaft next adjacent along the tunnel; 4,350 ft. of 36-in. steel main was laid to reduce a 16-ft. gradient slope across Central Park and improve pressures on high ground to the east. A contract is now under way for about 4,200 ft. of 48-in. and 3,800 ft. of 36-in. from 48-in. low service aqueduct mains eastward to improve upper east side low service pressure by reducing the present gradient slope of 32 ft. (or 14 lb. loss) in 5,000 ft. Contract is to be prepared for about 4,500 ft. of 30-in. main to reduce a present pressure loss between the Catskill tunnel source and the extremities of the system of 25 to 30 ft., and more fully utilize a Catskill shaft where output is now restricted.

Fire Supply Problems.—Fire supply presents an ever-present problem in all distribution systems. If the area in question is large and a possible fire draft a small percentage of the total consumption, the solution of the problem probably does not involve consideration of trunk mains, but rather tests to locate points where possible fire draft would exceed the limited capacity of the local grid-iron mains. If the consumption of area be small in comparison with a possible fire draft the solution may call for supply mains larger than necessary for the normal domestic and business consumption, in other words, the provision of suitable fire supply in such areas carried with it ample provision for daily consumption. In New York and other large cities, the areas involving the greatest hazards are protected by an independent fire supply system on which the pressure is raised at times of fire to suit the demand. Outside such protected areas of New York City, the solution of the problem of fire supply is based on tests made substantially as in other cities. A group of hydrants is selected for simultaneous discharge. Another hydrant on the side of the group opposite the apparent supply, or possibly within the group, is selected for observation of static and residual pressures. On signal from the man in charge, the observer at each discharge hydrant opens his hydrant fully and measures the discharge head by means of a pitot tube attached to a low reading pressure gauge, the gallons per minute discharged is obtained from curves of discharge at the various pressures and nozzle sizes. The observer at the pressure hydrant notes the static or normal pressure and the residual pressure with all hydrants open. The limit of capacity of the system at that location is estimated as the total discharge obtained from the group multiplied by the square root of the ratio of the static pressure to the drop in pressure observed with all hydrants open. If this limit of capacity falls below the requirements, of say third or fourth alarm, fires for that area, depending upon the hazard at that location, the final solution of the problem involves provision of mains whose size and location is usually obvious.

Occasionally the problem of safeguarding domestic and fire supply for an isolated high service area may be solved by insertion of check valves on the boundary between that and an adjacent low service of sufficient head to reach the high ground and under the head as reduced by the emergency demand. Such valves, if not in occasional action, should be watched and frequently tested.

Controlling Pressure.—In the problem of controlling the pressures in a system supplied by reduction of head at the source, automatic pressure regulation valves are frequently the logical solution. Such valves are used on the New York system, but usually not as extensively as originally intended. In general the non-use is not a discredit to the valve but has been due to the unusual condition imposed on its operation. The pilot valves of the automatic regular are actuated by variations of its down-stream pressure. In an overloaded supply main with a high friction loss between the source and the center of distribution the variations of demand in the system are not effectively transmitted as variations in pressures at the pilot valves, due to the law that the pressure loss varies as the square of the flow or demand and a serious increase in demand and consequently a much more serious pressure drop on the system is required to actuate the regulator at the source. Also a regulator midway on such a line cannot operate satisfactorily due to the added disadvantage of a highly varying

head on the up-stream side, the regulator tending to maintain a constant difference of pressure, transmits these variations to the down-stream side. Regulators working in parallel with nearby interconnection of their discharges have given unsatisfactory results due to the tendency for one of them to close as the other opens and vice versa. Where pressures have to be raised excessively at the source to maintain day-time pressures on the system the difficulty of utilizing regulating valves is obvious.

Underground Leakage.—The problem of control of underground leakage is a subject by itself and too broad to be included in this miscellaneous paper. It is, however, an important one, especially where subsurface conditions permit development of large and extensive leakage without surface indications. In New York City these conditions obtain in a very marked degree in the two boroughs of Manhattan and the Bronx. During years of plentiful supply and with a very small available force for the purpose we have been unable to do more than locate and repair leaks responsible for complaints of flows into basements, electrical conduits, steam lines, subways and other subsurface structures.

In the regular course, such complaints are received at the complaint desk of the main office and the order for investigation 'phoned to the repair shop of the district concerned. This order is followed by a copy of a written order, the original remaining at the office. Space is provided on the order blank for the foreman's report. When the leak is not found after a reasonable effort it is referred to the special waste detection force and is given study under engineering supervision. Practically every case thus referred is different and requires original and serious engineering study on the ground (and of conditions below ground) to solve the problem and locate the source, frequently a few blocks away, through a maze of subsurface conduits, gas and water mains, vaporizing steam lines, transit subways, etc.

It is anticipated that at or about 1935, New York City's consumption will have reached the capacity of its source of supply, and as this will probably precede availability of additional supply conservation measures are now being considered and adopted. Systematic surveys to locate and repair underground waste, much of which exists without causing complaint are being considered. One or two field parties are now being used on such surveys with the main object of determining how much underground leakage of this character can be stopped, what the cost will be per million gallons saved, what force and organization will be necessary to cover the fruitful fields in the reasonably few years available.

Aside from the saving of water such surveys by small districts are a decided help in maintenance by incidentally locating and correcting various defects, closed valves, open service boundaries, restricted circulation, etc. On the second of these experimental districts now under investigation an unexpected pressure drop occurring on the closing of the boundaries to isolate the district led to the location of a 6-in. wide open blow-off on a 20-in. main discharging 6 m.g.d., measured, into the sewer. This blow-off had not been indicated on distribution maps since about 1908, but from other evidence it is assumed that the blow-off had not been opened that length of time. We do not expect such "finds" in all of the trial districts to be investigated, but this case found in the second district investigated serves as a suggestion of one possible source of tremendous unobserved waste in a system that include hundreds of such blow-offs, and but for the district waste survey this one would still be running.

Acknowledgment.—The above is an abstract of a paper presented at the last annual convention of the New England Water Works Association.

Centralizing Control of City Machinery

The city of Reading, Pa., has recently centralized the custody and maintenance of its equipment such as motor vehicles, pumps, fire engines, etc., in the hands of one official. The office of supervisor of public machinery has been established, his duties being outlined as follows in the ordinance: He "shall have the care, management, direction, control and administration of the maintenance and repair of all motor vehicles, fire apparatus, pumps, and other machinery of every kind and description belonging to or used by any of the departments, bureaus, boards and other agencies of the city. All such departments, bureaus, boards and agencies shall obtain all repairs and replacement parts for machinery through the supervisor of public machinery, and not by direct contract with private parties, nor by having said repairing done under their own supervision. It shall be unlawful for the city controller to countersign, or the city treasurer to pay, any warrants or checks for repairs to, or replacement parts for machinery, except upon certificate of the supervisor of public machinery, that such parts or repairs have been obtained by his authority and under his supervision."

The supervisor is given authority to organize and manage a municipal machine shop in which all repairs to public machinery are to be made. All necessary equipment and repairs are to be procured through the office of the city purchasing agent.

Short Course in Public Administration

The short course in public administration held last summer at the University of Southern California was a decided success, and it is probable that it will be repeated in 1929. The individual attendance in various sections was 749 and the total section attendance was 5,430. The public occupations and positions represented by those in attendance comprised Assessors and Tax Collectors, Board of Education and Superintendents of Schools, Budgets and Efficiency, Bureau of, Building Departments and Building Inspectors, Chambers of Commerce, Clubs, and Organizations, Citizens, Clergymen, Clerks, City and County, Commercial Firms, Controllers, Treasurers, Auditors, Accountants, Councilmen, Engineers in Public Work, Fire Departments, Health Departments, Legal Departments, Managers, City, Mayors, Miscellaneous, Planning Organizations, City and County, Playground and Recreational Departments, Police Departments, Probation Department, Purchasing Agents, Social Welfare Workers, Street Traffic Organizations, University Students, Water, Power and Light Departments.

Average Life of Street Department Horses at Toronto, Ont.—The average life of a horse in the service of the Department of Street Cleaning of the City of Toronto, Ont., is 6½ years, according to the 1927 report of George W. Dies, Street Commissioner. The care of the department's 334 horses is under the direction of a veterinary surgeon, whose services are engaged on a per capita basis of $4.00 per horse per annum. His duties are to render the necessary veterinary services to sick horses, advise as to the proper feeding of the animals, and the necessary sanitary precautions against disease. He also examines and certifies as to the soundness of all new purchases, and condemns animals unfit for further service. During 1927 48 horses were purchased at an average price of $230 each. A card record is maintained of each horse as to date and from whom purchased, price, color, markings, age, height and weight. The time lost by horse, due to illness or other causes, is also recorded, as well as the date of disposition, cause, and sale price.

Washington, D. C., Has Spent Over $25,000,000 on Sewerage.—The total length of the sewer system of Washington, D. C., on June 30, 1927, was 868.97 miles of which 166.21 miles were main sewers and 702.70 miles were pipe sewers. The total cost of this system was $19,181,762. The length of the sewage disposal system was 39.52 miles and the cost was $6,237,292.

The City and Abandoned Street Car Tracks

How Some Cities Are Taking Care of the 9 Ft. Strip on Streets

SINCE the bus has superseded the street car in many localities, municipalities are faced with the problem of taking care of the 9 ft. strip which always was considered the direct possession of the utility using it. Cities are faced with a problem which was not anticipated even as late as the past five years. In many cases this area presents a very serious problem as it burdens the taxpayer to an extent which is not provided for in any way. How this problem is being handled in some cities was outlined by L. P. Booz, City Engineer of South Amboy, N. J., in a paper presented at the recent 9th Annual Conference of the International Association of Street Sanitation Officials, from which we have taken the matter that follows:

In some states the operating companies had to maintain the area occupied by their company and had to pave same whenever the street through which they operated was paved. They also had to keep this area cleaned and had to remove the snow therefrom in order to keep their franchise.

With the discontinuance of service and the abandonment of the tracks, the street area which is to be paved and maintained becomes 30 per cent wider and a 30 per cent greater burden to the taxpayer. An additional 9-ft. width had to be maintained, paved and kept clean, at an additional cost to the municipality.

In the State of New Jersey the car lines are automatically relieved of the burden of paving the before mentioned area. Utility companies which have been discontinued and failed because of a lack of travel on their lines, have abandoned the tracks and road bed as they existed. The final disposition of the tracks and road bed material in some localities where the service has been discontinued is still problematical. There is even talk of leaving the road bed as it exists and later continuing the service with its privileges should the necessity return.

The problem as it presents itself consists of restoring the street or roadway so that the public may acquire the full use of same as economically as possible.

The first condition encountered is where the tracks and road bed are abandoned on streets which are now paved to the full width between curbs, including that area paved by the street car company. The removal of tracks together with the ties, guard rails, and road ballast, would be a very expensive proposition, and in many cases the cost would be prohibitive. However, there are places where it is absolutely necessary to do all this work. Where the road bed has not been properly maintained, the ties will be found to be corroded and decomposed and in such condition that the road would continue to cave in because of the insecure foundation.

In some cases it is possible to remove tracks only and replace same with concrete or other foundation, and to surface the area formerly occupied by the track to a level with the surrounding roadway.

A still more economic procedure is to cover the rails with a thin layer of bituminous material which is sloped off on either side, so as not to make too great an obstruction, and allow for safer crossing than the track affords. In wet weather the tracks are often the cause of skidding of automobiles, and many accidents result therefrom. In some cases bituminous filler is used to bring the area occupied by the flange of car wheel to a level with the top of rail. This method can only be used where the grooved rail is laid.

The second condition met in the abandoning of street car tracks is the street in which the area between the tracks has not been paved. In a great many cases the operating companies have merely made a gesture toward maintaining their part of roadway, and with the abandonment of their lines there is a remaining 9 ft. which must be paved by the city, borough or municipal authority having jurisdiction therein. The method of paying for pavement improvements in most municipalities is for the city to pay a share and the abutting property owners on either side to pay the remaining share. This work is financed, bonds being issued for a definite term, and the city's finances regulated to meet the terms of the bond issue. This expense of a 9-ft. width of pavement is added to the property owner's or the city's share of the taxes, immediately causing a direct increase in taxes without any revenue being derived therefrom.

There are many townships in the State of New Jersey and in other states left either with a dangerous area 9 ft. in width as an additional expense, or as a menace to the traveling public. Unless the state and counties take a large share of this burden from the municipalities the conditions seem very unfair.

There are various opinions expressed as to the length of haul which is necessary in order for the street car to compete with the rapidly increasing busses. There are some traffic men who claim that there is a possibility of the street car coming back to take care of certain traffic conditions. The only way to solve this problem to the benefit of the taxpayers and the public at large would be to have the state make a thorough and comprehensive traffic study and make proper determinations as well as assist with the cost of resulting paving.

There is one great benefit to be derived by municipalities in which street car service is abandoned. The constant congestion and interruption of traffic caused by the use of street cars will be altogether eliminated and the public will have the use of the full width of the street. In a great many cities there is only sufficient width between the operating street car and the parked car for one line of traffic. Where the careless motorist does not properly park his car traffic is entirely stopped in that block until the street car passes the next street intersection. In this case the benefit is great and becomes the only cure of a traffic evil which was not anticipated, most of the street car companies having obtained their franchise when the only other street traffic consisted of horse-drawn vehicles. There are some cities in the State of New Jersey in which the street car traffic completely paralyzes other vehicular traffic in the main arteries of travel.

In conclusion I would say that there are many conditions of a local nature with which I am not familiar and which I have not discussed. But I believe for several years hence this problem will be a large and important one until the street cars are abandoned or until they are linked with the busses in an efficient and economical system of transportation.

Swimming Pool Classification in Colorado

The Colorado State Board of Health has divided public bathing places into three general classes according to minimum specifications for sanitation features. Class A bathing places are those in which there is no danger of infection, and their specifications require, among other things, scum gutters, the recirculation, filtration and sterilization of the water, and the maintenance of from 0.2 p.p.m. to 0.5 p.p.m. of residual chlorine in the water at all times that the pool is in use. Class B bathing places are those in which the danger of infection is slight, their specifications including the addition of clean water or the periodic sterilization of the water in the pool as suggested in a previous paragraph. Class C bathing places are those which are unsafe. Due to extremely limited funds and personnel, the classification of the pools in the state has progressed very slowly, but it is hoped that this work can be materially expedited during the coming biennium, so that the people may know the relative sanitary safety of bathing places they patronize and that the unsafe bathing places may be closed.

Routine Records of Collection Service for Refuse Material

Good Operating Records of Collection Service Important

By SAMUEL A. GREELEY
Pearse, Greeley & Hansen, Hydraulic and Sanitary Engineers, Chicago, Ill.

THE collection of refuse materials is generally recognized as an important part of the refuse disposal problem, and the maintenance of good operating records is obviously essential to the best and most economical service. Nevertheless, there is such a lack of uniformity in records of collection work and service that an examination of the subject is pertinent.

There are two aspects of the collection work which emphasize the need and importance of good operating records. In the first place, the collection of refuse commonly costs more than its disposal. Oftentimes the cost of collection is several times the cost of disposal. If records are kept establishing standards of work and cost, the tendency will be to see and seek chances to reduce the cost.

In the second place, the collection of refuse touches the individual householder more intimately than almost any other branch of municipal service. A high and uniform standard of service to householders should be maintained. Good records of the routine service rendered help materially to improve and remove areas or points falling below the established quality of the service.

Phases of Refuse Disposal Problem.—A pictures of the refuse disposal problem as a whole should be kept in mind, so that the function of the collection service can be properly considered. There are four parts or phases of the refuse disposal problem as follows:

(a) House Treatment.
(b) Collection.
(c) Transportation or Haul.
(d) Final Disposal.

The collection and the transportation or haul have to do with the work of collection units and are closely related. Where the haul from the last point of collection to the place of final disposal is short, the load haul is not so important as in larger communities where secondary or supplementary methods of transportation are required. Thus the collection must cooperate with the house treatment and must deliver the refuse to the disposal place in the most economical fashion.

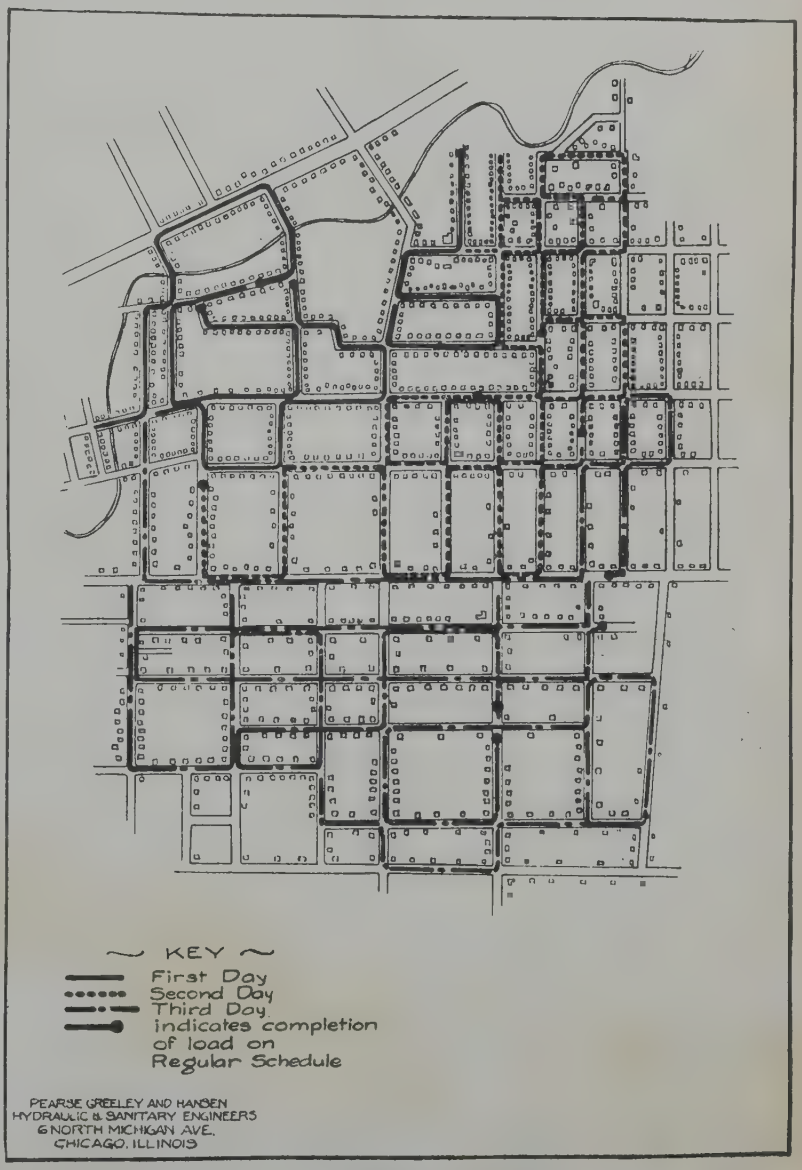
Functions of Collection Service.—The functions of the collection service are:

(a) To visit on a regular schedule every place where refuse is produced and where it has been decided to collect it.

(b) To pick up and haul away the refuse for disposal.

Thus one record or yardstick of the work is the number of houses to which service is rendered; and another is the measure of work done in volume miles or weight miles. Both yardsticks or measures indicate elements or service and cost and can be used to rate the functions of the collection service.

Collection Units.—The term "collection unit" is used to mean the vehicle and its attendants (driver, collector or helper) which actually make the collections. A collection unit may be a small horse-drawn wagon with one man, a horse-drawn trailer with two or three men, a large truck with a chauffeur and



Map Showing Route Record for Collection Unit for Collection of Garbage and Refuse

several collectors or helpers, or any similar vehicle. Different collection units are suited to different kinds of collection work and should, of course, be related thereto. Thus different sizes and types of vehicles are often used for collecting garbage, rubbish or ashes. The proper choice of the collection vehicle has a major bearing on the cost and efficiency of the service and operating records should be such as to guide the superintendent in the selection of suitable vehicles and in the most advantageous arrangement of the collection units.

Operations of Collection Unit.—The most important operations or work items in the routine of a collection unit include the following:

(a) Driving from barn or garage to first place of collection at the beginning of the route.

(b) Entering premises, picking up the accumulated refuse and placing it in the collection vehicle.

(c) Taking the loaded vehicle to the place of disposal.

(d) Unloading (and washing) the collection vehicle.

(e) Returning to a collection route for another load, or to the barn or garage for the night.

There are many minor operations along the way, such as hunting for hidden garbage cans, picking up spilled garbage, breaking out frozen garbage in winter, covering and uncovering the vehicles, reporting or handling complaints and the like. Such items affect the rate of speed of collection and are reflected in the number of houses to which service is given. Some of these operations are worthy of record such as reports on cans and house treatment problems and the handling of complaints.

Sheet Used for Recording Truck Progress

The Service Factor.—By service factor is meant the ratio between the total number of houses or points of collection in a district or along a route, to the number from which collections are actually made. In nearly all collection districts there are some houses not requiring collection, including those temporarily unoccupied and those where the refuse is burned or disposed of on the premises. The writer has traveled along collection routes where the service factor is as high as 95 and along others where it was found to be as low as 65 and occasionally less. The service factor is difficult to record on a daily or routine basis but it should be known, at least approximately, but the superintendent who wishes to give intelligent scrutiny to the collection records. The service factor as well as the character of the collection district as to density of population, extent of pavements and the like affects the rating of the collection work in so far as in different districts different rates of work apply. These items should be considered when using collection records.

Elements to Record.—The major elements or routine operating records of collection service include the following:

(a) Bulk Handled. This is a record of the weight and volume of refuse handled by a collection unit. It is sometimes recorded in tons or cubic yards, and sometimes in loads.

(b) Distance Traveled. This is an important index of work and cost. It is frequently recorded as the number of trips of each collection unit. The actual miles traveled is a better unit.

(c) Collections Made. The number of houses (or possible points of collection) as well as the actual houses served should be recorded as it relates the collection unit to a measure of output or work done or service rendered. The record of complaints may be included here.

There are, of course, other less important items to record, most of which can be included under one of the foregoing three elements. Among these are the quantity of gasoline and oil, the amount of feed for horses, vehicle repair items, new tires, time of unloading, character of refuse, weather conditions, etc.

It is quite the usual practice to record the bulk of refuse handled in tons or cubic yards. Less frequently the distance traveled is recorded. With speedometers so adaptable there should be little difficulty in recording the mileage of each collection unit. There are very few cities where the "collections made" are of record. One of these is at Birmingham, England, where James Jackson, Cleansing Superintendent, has an excellent route system for recording the work of the collection units in terms of houses visited or collections made. In some places costs are computed on a per capita basis, but this does not measure actual work in rendering service.

The writer, however, believes that a

record of the service as measured by the collections made is of great importance and of inestimable value in comparing the work and service of similar communities and of collectors in a given community. This element, taken with those of bulk and distance, completes the measure of a collection service. Thus the number of pick-ups or collections made per hour is a useful measure of the work of a collection unit. In normal summer weather, with cans at the rear door, no alleys, good pavements and a normally well built up district largely of single houses on 50 to 100-foot lots, a good collection unit should work along its routes at the rate of about 40 to 50 garbage collections per man per hour.

Cost Records.—Cost records should, of course, be kept as well as service records. The total monthly cost should be divided into a few major items such as labor, gasoline and oil, repairs and the like. These should then be tabulated and charted in the several units given above as the cost per ton, per ton mile and per collection made. If such tables and charts include the total expenditures and the number of units (tons, miles, etc.), as well as the unit cost, they will serve as summary tables for the use and guidance of the executive department.

Route Maps.—Single large scale maps of each collection district showing house numbers are useful. The routes to be traveled by each collection unit should be marked as illustrated on the map (see cut at end of paper). The collector should follow these routes and upon reaching the place of final disposal after each trip, he should report the last house from which a collection has been made together with a note of any difficulties or houses not served. The record clerk would then assume that all other houses up to this point had been served. If a complaint is later received, it is either unfounded or the collector is at fault. The position of the collection unit along its route is also indicated and if he is falling behind he can be given assistance and later his routes shortened or changed. The attached Truck Progress Sheet shows how the record of "collections made" can be kept in this way.

Summary Records.—There are many record sheets in use for the bulk collected and none is shown here. However, a column should be included somewhere to show the miles traveled. As columns in a monthly sheet, the following headings are suggested:

(a) Collection Unit (Number).
(b) Trips or Loads.
(c) Tons.
(d) Miles.
(e) Ton-Miles.
(f) Collections Made.
(g) Pounds per Collection Made.
(h) Collections Made per Load.

Such records should be totaled each month and the totals divided with the total cost to give unit costs of work and service.

Complaints.—The number of complaints received is a fair index of the efficiency of the service. Complaints should be recorded and given prompt attention. A form for recording complaints is shown on the following page. Such a complaint slip can be made up in blocks so that triplicate copies can be made by using carbon paper. Preferably each copy should be on differently colored paper. One copy is filed by the receiving or complaint clerk, one is put on a hook where it is picked up by an emergency or complaint collection unit, and one copy is given to the collection unit on whose route the complaint originated. The emergency unit should pick up it slips at noon and in the late afternoon or early morning, so that morning complaints are handled the same day and afternoon complaints before noon of the following day. The emergency collection unit chauffeur should make his report on his copy of the complaint slip and the chauffeur of the regular collection unit on his, and these two should be filed with the original. Where complaints are of such a character as to justify a special investigation, the results should be recorded on a special form as shown.

Annual and Monthly Reports.—The use of monthly and annual reports is twofold—(a) to inform the executives and heads of departments of the local government how the collection service is going and (b) to inform the local public and those interested from other cities. If routine operating records are kept, there should be no difficulty about the preparation of the reports. Thus the basis of good service is the routine record of operation.

Acknowledgment.—The foregoing paper was presented by Mr. Greeley at the 9th Annual Conference of the International Association of Street Sanitation Officials.

Missouri Conference on Water Purification

The fourth and most successful Missouri Conference on Water Purification concluded its meetings at Hannibal, Mo., Nov. 17. Interest in the program was evidenced by unusually good attendance of the 75 members and guests present, as well as lively discussions following the presentation of all papers.

Several changes were made in the constitution of the conference. The name was changed to Missouri Water and Sewerage Conference in order to indicate the present scope of interest including municipal sewerage as well as water systems. Provision was also made to accomplish affiliation of the Conference with the Federation of Sewage Works Associations.

The time and place of next year's meeting will be determined by the incoming Executive Committee. Following are the officers elected for the ensuing year:

Chairman, C. E. Heflin, Water Commissioner, Cameron, Mo.; Vice-Chairman, S. J. Duncan, Superintendent Waterworks, Moberly, Mo.; Secretary-Treasurer, H. D. Peters, Assistant Engineer, State Board of Health of Missouri; Executive Committee, W. V. Wier, Assistant Manager, St. Louis County Water Company, University City, Mo.; E. E. Wolfe, City Chemist, Hannibal, Mo.; W. P. Britain, Superintendent Waterworks, West Plains, Mo.; J. N. Wells, Superintendent, Joplin Water Works Co., Joplin, Mo.

Berlin Plans $96,000,000 Merger of City Railways.—The City Council of Berlin has decided to merge the city's vast transportation systems, comprising subway, elevated, motor bus and surface cars, into one undertaking with a capitalization of 400,000,000 marks (about $96,000,000). The new system will be known as the Berlin Transportation Co.

Cross-Connections Between Potable and Non-Potable Water Supplies

Final Report of the Committee of New England Water Works Association

SOME time ago the New England Water Works Association appointed a committee to make a study of cross-connections and to submit a report thereon. The committee consitsed of Robert Spurr Weston, chairman, John S. Caldwell, E. Sherman Chase, secretary; Stephen DeM. Gage, Chas. D. Howard, Arthur C. King, H. O. Lacount, Warren J. Scott, Stephen H. Taylor, and Arthur D. Weston. At a meeting of the association on Dec. 12 the committee presented its final report. The report, with the exception of the preface and the appendix, follows:

Definitions.—By a cross-connection is meant a connection between the distribution system of a public or private, potable water supply and a private or secondary, non-potable water supply.

One common example of a cross-connection is that between the public water supply of a municipality and the auxiliary fire-hydrant or sprinkler supply of a mill or factory,—the former sufficing for ordinary uses and the latter for fire fighting only. Another frequent case is where under ordinary conditions the public supply is taken for drinking purposes and for use in toilets and lavatories only,—water for all other purposes being taken from the secondary industrial supply. In a third common instance, water for various industrial processes, including boiler-feed water, as well as drinking water and water for toilets and lavatories, is taken from the municipal source, leaving the industrial source for private fire supply and miscellaneous industrial uses.

Connections are usually made through piping and gate-valves, with or without accompanying check-valves. Check-valves vary in type from simple, single, iron check-valves, with a swinging clapper, operating against an unfinished iron seat, to elaborate double, bronze, check-valves, like those devised and specified by the Associated Factory Mutual Fire Insurance Companies. The former are not precisely machined to prevent leakage, are usually rendered inaccessible by being buried in the ground, and are liable to rust so that the free movement of their clappers is obstructed. The latter are of excellent workmanship, are usually set in pits, or where they are accessible for inspection at all times, and are built of non-corroding bronze with rubber-on-bronze seats. This type of valve is equipped with gages and test cocks. (See accompanying figure on page 26.)

The Demand for Cross-Connections.—The principal demand for the establishment of cross-connections comes from fire insurance companies and from property owners who desire two rather than one source of water supply in order that there may be additional protection to life and property. Opposition to cross-connections has come principally from the health and water-works authorities, largely because numerous epidemics of disease have been traced to these connections.

Industrial Use.—Many large industrial plants and public utilities require a constant supply of water for boiler feed, for cooling purposes and for various manufacturing processes. To insure continuous operations, some secondary standby supply, instantly available in emergency, must be provided.

It is usually prohibitive in cost to purchase public water for ordinary uses and at the same time to store a supply of potable water sufficiently large for probable emergencies. Some way of using both the public supply and a secondary supply when needed is a practical necessity.

Fire Protection.—The automatic sprinkler has made it possible to concentrate with safety enormous values in industrial plants, mercantile buildings and warehouses. The manufacturers of the country have utilized this advantage to such an extent that adequate fire protection is now a necessity for the profitable continuance of their business. It is doubtful if the industrial development of this country could have been so extensive without the safeguarding influence of automatic sprinklers.

A good public water system is the very best primary supply for automatic sprinklers, and there is usually no practicable way of providing an alternative primary supply that is the equivalent of a good public water system. Even large elevated tanks storing water from the public supply and erected at great expense are necessarily of limited pressure and capacity. But municipal water supplies alone cannot be depended upon in all cases, for two reasons:

1. Fire will not wait in case the public water supply should happen to be out of service. If the tremendous advantages of automatic sprinklers in extinguishing fires at the start are to be realized, there must be pressure always on the sprinklers.

The Associated Factory Mutual Fire Insurance Companies have recorded about three hundred instances in which public water supplies have failed or been interrupted. In twelve of these instances fire broke out simultaneously with the interruption of the water supply.

2. Public water supplies are frequently inadequate in volume and pressure for the large number of automatic sprinklers and hose streams that might be needed to cope with a serious fire.

Therefore, whenever the value protected, or the fire or life hazard involved, is sufficiently great, a secondary supply is needed in order that automatic sprinklers shall control a fire at the start. The labor laws of New York State permit double the number of employees in buildings equipped with sprinkler systems.

It is often impracticable to provide a secondary supply of potable water of sufficient capacity to assure a volume of water adequate for an emergency, such as an unusually severe fire or a conflagration. Secondary supplies, of non-potable water, however, can be obtained in sufficient volume by utilizing open bodies of water, such as ponds and rivers. A cross-connection is at present the only practicable method of combining existing potable public water systems and available non-potable secondary supplies of large capacity, both automatically feeding into a common fire protective system capable of meeting the demands of sprinklers and hydrants during the progress of a fire. Such cross-connections, in order to function instantly when fire occurs, cannot be dependent upon manual operation but must be automatic.

Cross-Connections and the Public Health.—The following is a brief abstract of twenty-five instances on record where outbreaks of disease have been brought about by pollution of drinking-water supplies through cross-connections.

In nineteen of these instances the cross-connection contained a single gate—or check-valve. It must be borne in mind that a gate-valve is not an automatic device and that is affords no protection unless closed. In three instances, protection against mixing of unsafe with safe water was afforded by two gate-valves or by a check-valve and a gate in series, and in one instance there were two gate-valves and a check-valve in series on the cross-connection. In one instance, it might be assumed from the wording of the published record that protection against pollution was afforded by two gate-valves and a double check-valve arranged in series, although this was not definitely stated. In another case this condition was defi-

nitely stated. It is also true that one of the double check-valves that failed was of inferior type and that one had not been inspected recently.

In addition to the list of recorded cases of sickness or death due to pollution entering drinking-water systems through cross-connections with unsafe water supplies, the Conference of State Sanitary Engineers and several sanitary authorities have listed a considerable number of cases where trouble was caused by the introduction of polluted water through leaks in emergency intakes or by similar causes. The report of your committee, however, is limited to the effect of cross-connections, important as the other sources of danger may be.

Position of the Public Health Authorities.—While from the broad economic standpoint it may be undesirable to run the risk of fire losses and, possibly, some losses of life by accident to firemen and industrial employees in order to avoid the hazard of sickness and death due to the existence of cross-connections, the saving of life rather than of money must always be the dominant motive for sanitary authorities. The following may be given as examples of the reactions of sanitary authorities to this danger.

The position of New Hampshire is as follows:

"As a historical preface, it can be stated that this matter has been receiving consideration by the New Hampshire Board of Health for more than a dozen years. Attempts at reform had their inception when, as a result of some bad conditions discovered, a legislative bill was introduced which sought to prohibit the existence of any connection on a public water supply through which polluted water might be introduced therein.

"The opposition at the time of the industrial interests was so intensely manifested and the impossibility of establishing a flat prohibition was so obvious that this department next proceeded to consider the special safety devices that were then available. Manufacturers were advised that the situation involving single cast-iron check-valves, usually buried in the ground and commonly not even known to the water-works management, could not be permitted.

"A few of these manufacturers then proceeded to install special type double checks but most of them continued to 'stand pat,' or, while promising, to follow a procrastinating course. This they were able to do (1) because of the absence of any legislation and (2) because of the lack by this department of any adequate inspectional facilities.

"In 1919 a law was enacted prohibiting the maintenance of a connection of this character, except such as might be approved by the state board of health. There was included a proviso that 'every valve, gate or other device for controlling or preventing the inflow of water of unapproved character into the public supply shall be of such construction as to permit of efficient inspection and testing, and at actual test thereof shall be made not less than twice annually by the individual, corporation or association furnishing water to the public.'

"A beginning was then made toward the eradication of the single iron checks and manufacturers, in response to their inquiries, were advised that the least that could be accepted was the device as now commonly in use, suitably installed in a test pit. At the present time 67 New Hampshire mills have these double-check connections.

"Although recognizing that the ideal situation is one involving no connection whatsoever between a public water supply and a polluted industrial source, yet, with us it is a case of doing the best thing possible in view of existent facts. While admitting that no such device affords an infallible means of protection, yet it also cannot be denied that no form of protective action against a polluted water supply can be said to be infallible, these depending, as all of them largely must, upon the human factor.

"Accordingly, it is the present policy of the New Hampshire Board of Health to permit, for the purpose of fire protection only, of the use, in lieu of mechanical severance, of a suitable connecting device of the best approved type, providing also that such be installed in a proper test pit, and maintained under periodic inspection."

In December, 1926, the Rhode Island State Board of Health, while without authority to prevent the installation and use of cross-connections, adopted a resolution advising that all such be abolished.

In its bulletin of January, 1927, the Connecticut State Department of Health published an article by the Director of its Bureau of Sanitary Engineering. In this article, the author cites the regulations of the department, namely, that after Dec. 31, 1926, no cross-connections shall exist between potable and non-potable supplies, except that installations protected by double check-valves of approved type with adequate facilities for testing that were in existence on Dec. 31, 1926, may be temporarily continued with the approval of the State Department of Health. The latter provision was inserted because it was felt that double check-valves of the latest approved type should be given a fair trial. The length of extension of time granted will depend upon investigations that the department is now making as to the efficiency of the newest types of valves. No new installations of double check-valves are allowed.

In New York State the Public Health Council of the State Department of Health adopted on Nov. 12, 1925, an amendment to its sanitary code which prohibited cross-connections between non-potable and potable water supplies after July 1, 1926. This regulation permitted the continuance of cross-connections where two gate-valves with indicator posts and two check-valves of the special design of the Factory Mutual Fire Insurance Companies or equal were installed, but such connections were to be discontinued after July 31, 1928. The regulation also permitted the use of dual water-supply systems where the auxiliary supply was delivered to an elevated tank, provided the connections were made through an open discharge pipe above the high-water line of such tank.

On June 27, 1928, the Public Health Council voted to grant a further extension of six months. On July 3, 1928, the Commissioner of Health sent a letter to water-works authorities throughout New York State saying that, as a result of the development of a special fire-pump chlorinator, it was the opinion of the department that the installation and proper maintenance of such a chlorinator would satisfactorily meet the requirements of the sanitary code. The letter further outlined certain conditions that were to be met prior to the approval by the department of such cross-connections. Among these conditions was one calling for the proper installation of all-bronze, double check-valves between the fire-supply system and the municipal system. A copy of the letter is given in Appendix G.

In New Jersey a new chapter (Chap. XIII) to the Sanitary Code, enacted by the State Department of Health on Sept. 18, 1928, reads as follows:

"Regulation 1: A physical connection shall be considered as any cross-connection, by-pass, valve, pipe line, auxiliary intake, or other similar device which permits or may permit any flow of water into an approved public potable water supply from any other water supply unapproved by the Department of Health of the State of New Jersey, or any source of water supply not fully treated in accordance with the terms of the provisions of the permit issued for or the rules and regulations governing the supplying of such water for public potable purposes by the Department of Health of the State of New Jersey.

"Regulation 2: That after April 1, 1929, physical connections shall not be permitted, except where such physical connections existing on April 1, 1929, include two all-bronze check-valves with rounded rubber facing, two gate-valves with indicator posts, or rising stems and drip cocks and gauges for testing, and such physical connection is located in a vault or pit of water-tight construction readily accessible for inspection: and,

"Provided, That the application for the continuation of such a physical connection is made to the local board of health having jurisdiction and is approved by such local board of health, the date of continuance may be tem-

porarily extended by the Department of Health of the State of New Jersey."

General Code of the State of Ohio, Section 1252-3:

"It shall be unlawful for any official, officer, or employee having in charge or being employed in the maintenance and operation of a public water supply and water-works system or for any other person, firm or corporation to establish or permit to be established any connection whereby a private, auxiliary or emergency water supply other than the regular public water supply may enter the supply or distributing system, unless such private, auxiliary or emergency water supply, and the method of connection and use of such supply shall have been approved by the State Department of Health."

Other states have made similar regulations but the above will suffice for illustration.

Action of the American Water Works Association.—The fire-protection division of the American Water Works Association adopted the following resolutions at Louisville, Kentucky, May, 1925:

"WHEREAS cross-connections between potable public water supplies and supplies from other sources have been the cause of a large number of outbreaks of typhoid fever and other water-borne diseases, and

"WHEREAS, check-valves and other similar protective devices cannot always be depended upon, be it

"RESOLVED, that no physical connection should be permitted between a potable public water supply and any other supply except as follows:

1. With another potable public supply.

2. With a potable supply which is regularly examined as to its quality by those in charge of the potable public supply to which the connection is made.

"This prohibition to apply to all piping systems either inside or outside of any building or buildings, and

"BE IT FURTHER RESOLVED, that definite programs should be inaugurated in each municipality to permanently eliminate all other connections.

Action of the Conference of the State Sanitary Engineers. — The following resolutions were adopted in 1926 by the Conference of State Sanitary Engineers:

"WHEREAS, cross-connections, auxiliary intakes and by-passes between potable public water supplies and supplies from other sources have been the cause of a large number of outbreaks of typhoid fever or other water-borne disease, and

"WHEREAS, check-valves and other protective devices, or notifying the public in the case of using water from a polluted source through an auxiliary intake or by diverting the flow around an integral part of a purification plant through a by-pass, cannot be depended upon to adequately protect the public from disease,

"BE IT RESOLVED, that no physical connections should be permitted between any potable public water supplies either through cross-connections, auxiliary intakes or by-passes and other supplies except as follows:

1. With another potable public water supply.

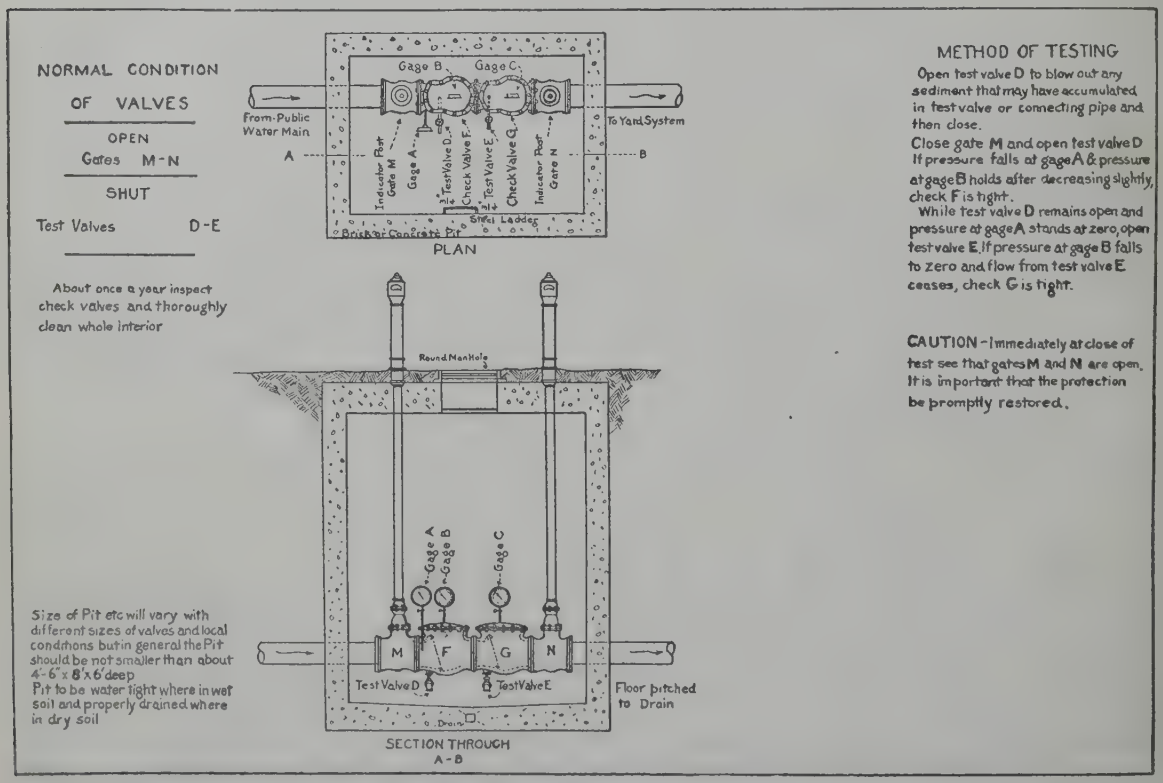
2. With a potable supply which is regularly examined as to its quality by those in charge of the potable public supply to which the connection is made.

"This prohibition to apply to all piping systems, either inside or outside of any building or buildings, and be it,

"FURTHER RESOLVED, that definite programs should be inaugurated in each state and each municipality thereof to permanently eliminate all other connections, and be it,

"FURTHER RESOLVED, that the Executive Committee of this conference transmit copies of this resolution to the Fire Underwriters Association and related organizations, also the American Water Works Association, New England Water Works Association and other analogous organizations with the request that they cooperate in securing the carrying out of the provisions of this resolution."

In its report which recommended this resolution for adoption by the Conference, the Committee defined cross-connections, auxiliary intakes and



NORMAL CONDITION OF VALVES

Floor pitched to Drain
Drain
SECTION THROUGH A-B
Size of Pit etc will vary with different sizes of valves and local conditions but in general the Pit should be not smaller than about 4'-6" x 8' x 6' deep
Pit to be water tight where in wet soil and properly drained where in dry soil
METHOD OF TESTING
Open test valve D to blow out any sediment that may have accumulated in test valve or connecting pipe and then close.
Close gate M and open test valve D If pressure falls at gage A & pressure at gage B holds after decreasing slightly, check F is tight.
While test valve D remains open and pressure at gage A stands at zero, open test valve E. If pressure at gage B falls to zero and flow from test valve E ceases, check G is tight.
CAUTION - Immediately at close of test see that gates M and N are open. It is important that the protection be promptly restored.

Fire Service Connection Using Two Check-Valves—of Approved Type—Connecticut State Department of Health

by-passes; presented a tabulation of outbreaks of typhoid fever and in some instances of enteric diseases traceable to cross-connections, auxiliary intakes and by-passes. This tabulation includes a total of 8,028 cases of typhoid fever with 226 deaths and also more than 11,000 cases of enteric disturbances.

Appended to the report are the results of the questionnaire summarizing the procedure for elimination of cross-connections, etc. As an example of what may be done, the experience at Chicago may be cited. A survey disclosed 428 cross-connections of which 179 were direct and 249 indirect. By the end of 1925, 85.3 per cent of these connections had been removed.

Legal Liability.—The legal cases cited in the report of the state sanitary engineers support the position that municipalities that through their officers permit cross-connections with polluted supplies become legally responsible for any epidemics resulting therefrom. In the opinion of the Committee they become legally liable if the epidemics result from any negligence in the design, installation, operation or inspection of said connections. It is also true that equal, if not greater, responsibility rests upon state authorities regarding cross-connections even though it be moral rather than legal.

Relative Hazards.—In the 296 cases of interruption or failure of water supplies, recorded by the Association Factory Mutual Fire Insurance Companies, there were 12 cases where fires occurred simultaneously.

In the 8,028 cases of typhoid and over 11,000 cases of enteric disturbance, resulting in 226 deaths, the losses by death and disability reached millions of dollars. Most of the deaths followed pollution passing through single valves or checks.

Apparently no single valve on a connection between a potable and a polluted water supply affords sufficient protection, and even the best installation of double check-valves may fail for lack of inspection.

Importance of Inspection. — Where double check-valves are inspected frequently and where they are thoroughly overhauled annually, the danger due to cross-connections is greatly reduced. The permissibility of the best installation, other things being equal, therefore, hinges upon the frequency and kind of inspection.

Results of inspection of 1,032 sets of double check-valves by the Associated Factory Mutual Fire Insurance Companies showed only four cases where both valves were leaky, and in these four leakage was slight and due to lack of care. An instance has been cited*, however, where both clappers of a double check-valve installation were held partly open by a pair of overalls, thus again emphasizing the necessity for frequent inspection.

Data regarding cross-connections in New Bedford are of interest. Here the check-valves are inspected at least twice a year, and the results show both valves leaky in two out of 2,152 tests or less than one case in 1,000 inspections. Many of the installations were not of the latest type.

The results of the first year of periodical testing of double check-valves by the State Department of Health of Connecticut show that out of 624 tests on iron-body check-valves, there were 24 cases where one leaky valve was found and one case where both valves were found to be leaky because of unevenness in the flat, rubber seat-facings. Of 273 tests of the all-bronze valves, leaky valves (outside only) were found in 3 cases and in no case were both valves leaky.

In view of the large number of cases of sickness and death, the neglect of even the best devices is dangerous. No pains should be spared to make inspections thorough. The Committee realizes the difficulty in establishing a procedure that will prove effective for all conditions, all types of installation and all places. To indicate broad general principles rather than routine procedure seems to be the work of this committee. Nevertheless, it is believed that good results may be obtained by quarterly inspections. Furthermore, the Committee believes that, where possible, inspections should be made through the cooperative efforts of both state and municipal authorities on the one hand and the property owners and insurance companies on the other. Installations in each municipality should be examined by a state official or other competent water-works authority at least once a year.

The attention of water departments is called to the frequency of unknown and unprotected connections, not only as regards their existence but also as regards their type and condition. This relates particularly to old installations. All such connections should be sought out and, when found, should be abolished or protected.

The Committee appreciates the cooperation of the insurance companies as exemplified by the action of the Association Factory Mutual Fire Insurance Companies who are chiefly interested in the protection of factories and mills as contrasted with general fire protection. These companies at their executive meeting on Dec. 12, 1927, adopted the following procedure:

"a. See that every set of double check-valves, both old and new, receives the necessary supervision. Experience has shown that many risks do not appreciate the importance of keeping the double check-valves clean and tight by means of an annual overhauling. Our work would be in the line of education and assistance."

"b. Pending the decision in each case as to the final outcome, see at once that every single check-valve between potable and non-potable supplies is made accessible and kept tight as is being done in the State of Massachusetts."

"c. Make a study of fire-service connections at our plants both insured or prospective, and determine where it would be wiser to eliminate cross-connections and where best to provide other supplies. Then for those risks where cross-connections should be retained, have all-bronze double check-valves put in and provide for periodic and effective supervision of them as outlined in paragraph 'a' above."

As representing the attitude of other insurance companies the following may be quoted from a letter of George W. Booth, Chief Engineer, National Board of Fire Underwriters, published in the June 3, 1920, issue of the Engineering News-Record:

"The fire-protection engineer is not the responsible party in making the connection originally or in its continuance. Insurance standards require, for complete reliability, two independent sources of supply, and the plant management or the municipal authorities may, and often do, use one source which is unsafe or questionable from a sanitary standpoint, for the reason that it is a cheaper or easier one.

"The engineers of the National Board of Fire Underwriters do not, and we believe other engineers should not, favor such connections, but there are cases where they have already been made, and it is not possible, without the charge of discrimination, to refuse credit for them as emergency sources. It is, however, standard practice with many of the insurance bureaus to recommend secondary sources of supply which will be safe, as for instance, a storage reservoir.

"The double check-valve, designed some years ago for use on connections to sources of doubtful quality, has been permitted by some health authorities and has a satisfactory record. It should be installed most carefully and be maintained under a thorough inspection system."

Recent Developments in Chlorination.—A method of overcoming the dangers of cross-connections between safe and unsafe water supplies suggested in the past was to sterilize secondary supplies used for fire by installing chlorinators on fire-pump suctions. Fire pumps, however, are normally idle, being merely "turned-over" once a week to be sure that they are in operative condition; and once a year, during the summer, they are tested to capacity by means of hose lines attached to the yard hydrants.

A chlorinator attached to a fire pump, therefore, would normally be inoperative, and hence was not considered dependable, if called upon suddenly to operate in the emergency of a fire after having stood idle. Manu-

* Jour. N. E. W. W. A., Vol. XXVI, p. 406.

ally controlled chlorinators were also considered unreliable, because the operator of the pump, in the excitement of a fire, might forget to turn on the chlorine supply.

One manufacturer of water-works chlorinating apparatus has been at work on the problem, and has recently developed an automatic start-and-stop chlorinator, especially designed to be connected to fire pumps. This machine, which is of the vacuum type, utilizing liquid chlorine by reducing it to a gas, is so designed that a small auxiliary injector continually draws a small amount of chlorine gas and discharges it to waste, thus keeping the apparatus primed and assuring that it is always in operative condition. When the fire pump starts, a main injector draws the chlorine gas and discharges it in solution to the point of application of the fire-pump suction.

There is no need of proportioning the amount of chlorine exactly to the amount of water discharged, as is necessary in water-works practice, because the water delivered by the fire pump is not used for domestic purposes. The fire-pump chlorinator, therefore, discharges into the pump suction an amount of chlorine sufficient to care for the maximum draft from the pump, regardless of what is actually being delivered.

This chlorinator has been tested by the engineers of the New York State Department of Health. As a result of these tests, that department permits the retention of cross-connections under certain conditions, if chlorination is applied to the secondary supplies.

Conclusions.—The Committee recognizes that the only absolute safeguard for the purity of water supplies is complete separation of potable and non-potable supplies. Many cases exist in industrial as well as fire lines where cross-connections can be entirely eliminated without extensive changes or undue hazard to life and property. Such connections should be immediately abolished. In other instances the abolition of such cross-connections presents a very serious problem from the standpoint of possible loss of life and property by fire. Each case should be carefully studied on its own merits to determine the best procedure, all interests being considered. So far as possible steps should be taken in each community to provide public water supplies of sufficient adequacy and reliability, even to providing a secondary potable supply if necessary, so as to eliminate the necessity for cross-connections of any kind.

The Committee feels that pending the establishment of adequate and reliable supplies for protection of life and property from fire, experience to date indicates that double check-valves of the latest improved type, properly installed and adequately supervised, furnish the best protection of any single device now known. It is essential, however, that such installations be regularly and frequently inspected and tested. Installations of this type are relatively recent and whether or not such installations, give sufficient protection, is a question that is still open for decision on the basis of further experience.

The Committee is of the opinion that the recently developed chlorinator for auxiliary supplies offers another valuable means of defence against bacteriological contamination of public water supplies through cross-connections. However, the Committee believes that more experience must be gained with this device, before it can be unqualifiedly recommended. Properly operated and maintained, the device provides a method for making polluted auxiliary supplies, bacteriologically safe, even though such supplies might continue to be non-potable.

Your Committee does not approve the use of cross-connections between safe and unsafe supplies, and wherever auxiliary supplies are made safe by treatment there should be provided the additional safeguard of proper and properly installed and inspected double check-valves. Furthermore, these valves should be used between drinking water supplies and those that while unpotable,—like pure sea water,—do not require treatment to make them safe.

The Committee strongly urges that states adopt suitable laws and regulations covering the control of cross-connections and that in each community an investigation of the existing cross-connections be made immediately and a program for the elimination or control thereof be inaugurated by the local authorities. The Committee also urges that, where possible, the inspections be made through the cooperative efforts of state and municipal authorities on the one hand and owners and insurance companies on the other. Inspections of all installations of protective devices should be made at least quarterly by an official responsible for the quality of the public water supply and such devices should be overhauled yearly.

While this report is largely concerned with cross-connections for fire service, there are many other cross-connections like those with sewers, around water-purification plants and through auxiliary intakes. None of these should be permitted.

Your Committee recommends that the following resolution be adopted by the Association:

"WHEREAS, evidence shows that the existence of certain cross-connections between safe public water supplies and unsafe private water supplies, not equipped with modern protective devices, has resulted in many outbreaks of disease and many deaths, and

"WHEREAS, such cross-connections are a hazardous part of any water-supply system.

1. This Association recommends that no cross-connection be permitted with a supply that in the opinion of the State health authorities is bacterially unsafe.

2. This Association recommends that any cross-connection permitted with a bacterially safe but non-potable supply shall be made through a properly installed and adequately supervised, all-bronze, rubber-seated, double check-valve of a type approved by the State health authorities.

Ohio Sewage Treatment Conference

The second annual Ohio Conference on Sewage Treatment was held at Marion, Oct. 31, with attendance of about 100. Of the 85 municipal sewage treatment plants in Ohio, 41 were represented by one or more persons. There were also present a number of city officials having to do in one way or another with sewage treatment plant operation.

The program was to some extent diversified, the topic of sewer rental law and its practical operation receiving lively discussion. The latter portion of the afternoon was devoted to an inspection of the Marion sewage treatment works.

Officers elected for the ensuing year were: C. C. Hommon, Canton, chairman; G. E. Flower, Cleveland, vice-chairman; Floyd G. Browne, Marion, secretary-treasurer; F. E. Sheehan, Portsmouth, member-at-large of the executive committee.

No decision was made as to next year's meeting place, but a very cordial invitation was presented by the officials of Akron.

Mosquito Survey Under Way for Toledo, O.

A survey to find out what steps are necessary to rid Toledo of the mosquito nuisance has been started under the direction of Major E. M. Skinner of the mosquito control division of the Gorgas Memorial Fund.

The survey, which is being underwritten by the Toledo Chamber of Commerce, will include an investigation of polluted and stagnant pools and streams. When the survey is completed, the findings as to causes and an estimate of the probable cost of elimination will be presented to council. There is some possibility that the city and county might jointly finance the necessary expenditures to allow the people of Toledo and Lucas County to sleep in peace during July and August.

Boston Company Acquires Five West Virginia Utilities.—The Atlantic Public Utilities Corp., Boston, Mass., has purchased five water and electric companies in West Virginia. These are Weston Water Co., Glenville Electric Co., the St. Albans Water Co., the Dunbar Water Co., and the East Rainelle and Oak Hill Water Co.

Asphaltic Pavement Construction in the City of Pittsburgh, Pa.

Sub-Base Treatment, Base Proper and Top—Materials and Methods

By J. J. PAINE
Director, Pittsburgh Bureau of Tests

IN Pittsburgh we have hundreds of miles of good streets, and like every other large city, we have a few that are not so good. Pittsburgh has many difficult engineering problems and often a very short street will pass over sand, clay, shale, rock and filled ground with exceptional grades, and curves, along hillsides and ravines.

Causes of Failures.—Five years after the World War, we found a number of our streets breaking up. There were some unpleasant rumors. The contractors said it was due to poor materials, and the materials people blamed the cause on everything else. So we had an extensive investigation and numerous conferences.

Taking thirty streets that varied from one year to ten in age, our report was something as follows:

21 streets—poor workmanship and design.

7 streets—poor materials and design.

2 streets—poor inspection and design.

In every case we see design as one of the contributing causes. Our Engineering Bureau in Pittsburgh has as many capable and competent engineers as any city in the country. We were following standard practice for that time. Careful preparation of the sub-grade; a 6-in. 1:3:6 concrete base, with a standard block stone, brick or asphalt top.

Now please do not jump to conclusions. I am talking about heavy traffic streets. We have numerous residential streets built on this method, 15 years or more old, and still giving excellent service. Also allow me to explain more at length the nature of these failures.

Base Failure Due to Heavy Loads.—In 90 per cent of the cases, the cause was base failures; the pavement had worn out from the bottom up, rather than from the top down. The street had failed under the terrific demands of increasing traffic. We also noted, that in nearly every case where there was a failure, that the sub-grade had sunk, shifted or in some way changed from its original contour. I might add, that at this time, there were hundreds of solid tired trucks hauling coal, steel, gravel, cement, etc., with loads of from 10 to 15 tons and some even higher. At present we are trying to limit tonnage and make all trucks use pneumatic tires.

Experiments conducted by our laboratory indicate that the impact of a truly solid wheel tire varies in force in approximately the same ratio as that of the force imparted by a free falling body. Thus we see that heavy solid tired trucks, having chains on, will give continuous impacts of from six to eight times its dead load, per rear wheel. Often these stresses set up in a pavement are above the strength of the materials and unless properly distributed the result is failure of the pavement.

For the last ten years many of us have been attending concrete, brick, asphalt, and other association meetings all over the country and it is only on rare occasions that we ever hear someone suggest that a proper foundation should be put under a pavement. That is supposed to be an axiom but in many cases, I find it to be only a postulate. We discuss this and that kind of pavements, extol its virtues, and go along our way as if it can be placed on thin air. Perhaps there is little discussion of sub-grades and sub-bases, because there is no association in their behalf, but I believe it would be well for representatives of different associations and material salesmen, to study, design, and work out for their respective districts and communities the proper kind of foundations for local conditions and materials; it would often save many embarrassing explanations and excuses for failure of their materials.

Sub-Grade Preparation.—So if we are going to make any real attempt toward constructing an Ideal Pavement, the first thing to be considered is the foundation. We speak of adequate drainage. The drainage facilities should always be more than adequate. Next, proper preparation of the sub-grade. Unless the sub-grade is thoroughly stable, that is, will resist temperature and moisture changes under all conditions, it has not had proper preparation. A sub-base treatment should then be resorted to.

In the Pittsburgh district the sub-soil is principally clay. On account of the fact that clay soils have certain undesirable characteristics as regards their behavior under influence of moisture and temperature, they cause much trouble in pavements which are laid on them. This holds true regardless of the type of pavement. Consequently, many experiments, with stone, gravel, and slag, have been tried in order to find some way of eliminating or at least conteracting or reducing these harmful effects.

One way is the use of a cushion blanket of granulated slag 3 or more inches deep. This method seems fairly successful when held between curbs.

Another method is to mix a granular material with the clay instead of compacting it in a layer over the clay. I refer to the method developed by Prof. H. Eno of Ohio State University. Also, A. T. Goldbeck, 1924, American Association of State Highway Officials.

In the past we used a rather coarse aggregate ranging from 1½ in. to 3 in. The aggregate was placed in two layers with a total thickness as shown on the contract plans, which is ordinarily 3 in. in thickness. The first layer is thoroughly rolled in to and incorporated with the sub-grade. The second layer is then spread and rolled until creeping before the roller ceases and all the material is locked or keyed. After this second rolling the voids in the top layer are filled with aggregate ranging from ¼ in. to ¾ in. and thoroughly consolidated by rolling.

More recent experiments with hard air cooled slag have given excellent results. The principle involved here is exactly the same as that in the construction of so-called "traffic bound" roads. This principle is that of increasing the internal friction in the sub-base and hard air-cooled slag is apparently giving the best results; this is probably due to the rough surface texture of the slag particles which must necessarily give greater friction than would smooth surfaced particles of the same size.

The advantages of a sub-base treatment are several. First, it gives a permanent even and uniform solid foundation. Second, it can be cut into if necessary and again repaired without great difficulty. Third, it forms an effective drain whereby the water may be carried to the curb drains and prevent saturation of the base. Fourth, it forms a moisture barrier between the sub-soil and base and prevents continued transmission of moisture by capillary attraction. Fifth, more uniform conditions, with especial relation to moisture. Six, increased bearing power which helps to distribute stresses and absorb heavy impacts.

The Base.—The base proper, which is usually concrete or reinforced concrete, needs but little discussion at this time as all engineers are familiar with the latest methods of design and construction. However, I wish to state that I am not in sympathy with local

mixes. Anything leaner than a 1:6 (approximately 1:2:4) mix has proven extremely unsatisfactory in Pittsburgh. Also, without going into the mechanics and mathematics of the problem, I believe that nothing less than an eight in. base should be used for heavy traffic streets.

Perhaps, in the next few years, we may see considerable changes in the base types. A base that is rigid, strong, resistant to moisture, more free from expansion and contraction stresses, yet more flexible, and easier to cut into and repair.

Slag Aggregate for Binder.—In Pittsburgh, we have a decided preference for sheet asphalt as the result of many experiments and practical experience. The usual 1.5 in. binder and 1.5 in. wearing courses are used. The coarse aggregate for the binder course is slag, having the following requirements: Slag shall consist of air cooled blast furnace slag of clean, tough, durable pieces, non-glassy in character. Dried slag when tested according to the methods of the American Society for Testing Materials, Serial Designation, C 29-27, shall weight not less than 70 lb. per cu. ft. All the material must be retained on a 10 mesh screen.

At least 25 per cent shall pass a ⅜ in. circular opening; at least 30 per cent and not more than 50 per cent shall pass a ⅝ in. circular opening and be retained on a ⅜ in. screen; at least 90 per cent shall pass a 1-in. opening; and 100 per cent shall pass a 1¼-in. circular opening.

We have found slag to be the most satisfactory of all our local materials and have between 300 and 400 miles of binder laid with this material.

The bulk of our sand has been a well graded silica lake sand.

The Filler.—The filler has been limestone or silica dust. For the last five years we have obtained very satisfactory results with silica dust, a by-product from glass plants. We have used this as a filler up to fairly high percentages. Its grading is approximately as follows:

	Per Cent
Passing 300 mesh sieve	81.5
Passing 200 mesh sieve	90.0
Passing 80 mesh sieve	98.0
Passing 50 mesh sieve	100.0

All asphaltic cement used met the regular standard specifications.

The Binder Mixture. — The binder composed of coarse aggregate, sand and asphalt was mixed in approximately the following preparations:

	Per Cent
Asphaltic cement	4.0 to 6.5
Fine Aggregate	20.0 to 35.0
Coarse Aggregate	58.5 to 76.0

With at least 25 per cent of the fine aggregate retained on a 40 mesh screen.

With at least 25 per cent of the fine aggregate retained on a 40 mesh screen.

Oftentimes there seems to be a tendency towards laxity when preparing and laying binder, but as much care in the preparation and placing of binder should be exercised as in that of the wearing course. Design of mix, temperatures, raking, compression, thickness, and even contour should be carefully adhered to. The binder is not just a filler to bring the streets to established grade; it is a foundation, and unless there is a definite bond between the binder and the base, and the binder and the top, it is not fulfilling its purpose.

This year the City of Pittsburgh definitely adopted the high dust filler and void theory of design for wearing surface on heavy traffic streets. Our mixture contains the average preparations as follows:

	Per Cent
Bitumen soluble in carbon tetrachloride	8.5 to 10.5
Bitumen soluble in carbon tetra-4....	NU NU U
Dust passing a 200 mesh screen	18.0 to 30.0
Sand passing a 80 mesh screen	15.0 to 25.0
Sand passing a 40 mesh screen	20.0 to 35.0
Sand passing a 10 mesh screen	15.0 to 25.0
Sand passing a 4 mesh screen	0 to 5.0

Preparing Wearing Surface. — Our specifications for preparing and laying wearing surface are as follows:

The sand and asphalt cement shall be heated separately. The temperature of the asphalt cement shall be maintained between 300 and 350 F. at the discharge pipe. The temperature of the sand in the mixer-box and after adding the filler, shall not exceed 450 F. Specified proportions of filler and hot sand, determined by weight, shall be immediately mixed in an approved mixer. Then shall be added the hot asphalt cement in the stipulated proportions and the whole mixed for at least one and a half minutes or long enough to effect a thoroughly homogeneous mixture.

In preparing the wearing course mixture in a pug-mill mixer, the combined weight of mineral aggregates, including filler plus asphalt cement, shall not produce a volume of material in excess of that which will find its normal level in the mixture-box slightly below the top of the mixer blades when said blades are exactly vertical.

Laying Wearing Surface.—Upon the binder course shall be laid the wearing course as described below.

The asphalt wearing surface shall be hauled to the work in trucks equipped with canvas or other suitable covers and shall leave the plant at a temperature of between 375 and 425 F. as suitable for the asphalt used and air temperature. Upon arrival at the street, it shall be deposited at least 10 ft. ahead of the work, upon the clean binder or a movable platform from which all mixture shall be distributed to the place where it is to be raked. The temperature of the mixture shall be not less than 350 F. The shovelers shall carry each shovelful to its place, in front of the rakers, and turn it over as deposited. Rakers shall not be allowed to walk in the hot mixture. The hot mixture shall be uniformly distributed and thoroughly raked to full depth upon the asphaltic binder (which shall be thoroughly dry, free from leaves or other foreign matter) so that after receiving its ultimate compression by rolling, it shall have an average thickness of 1.5 in. Any material that is lumpy or does not break down easily must be wasted. Immediately after the mixture is raked it shall be luted transversely of the pavement by means of a lute 5 to 6 ft. long, operated from the sides of the pavement. Strokes with the lute shall overlap each other at least 2 ft., and shall extend beyond the center of the pavement. The initial compression shall be effected by means of a three wheeled roller, weighing not less than 12 tons, used longitudinally to the pavement, after which a small amount of portland cement shall be swept over the pavement. Rollers must get on to the work as soon as practicable. Final compression shall be effected by means of a tandem roller weighing not less than 10 tons. Rolling shall be steadily kept up at the rate of not more than 200 sq. yds. per hour until all roller marks shall have disappeared and the surface gives indications of no further compressibility, and free from elevations and depressions more than ¼ in. under a 6 ft. straight edge placed longitudinally to the pavement. Roller paths shall at all times overlap by half the width of the roller.

The mixture after final compression shall show a density by the specific gravity method of not less than 85 per cent of the specific gravity of the mineral aggregates contained therein.

The mixture shall average not less than 155 lbs. per sq. yd. of surface.

No mixture shall be laid in the rain or when the binder has water standing upon it or when the weather conditions are unsuitable. Care should be taken to apply water to the roller wheels in just sufficient quantity to prevent hot mixture adhering, and with no excess so as to cause blistering. All blisters must be broken up with a rake or raked out and replaced with fresh material. Cross and diagonal rolling should not be undertaken until the mixture will stand same without checking and such rolling shall be done only with the tandem rollers.

The notion of the roller shall at all times be slow enough to avoid displacement of the hot mixture and any displacements occurring as a result of reversing of the direction of the roller or from any other cause, shall be corrected by the use of rakes and fresh material where required. For a radial distance of 8 in. around all structures, manholes, curbs, gutters, or other locations, inaccessible to the roller, the compression shall be effected with hot iron tampers weighing not less than 25 lbs. and having a bearing area not exceeding 48 sq. in.

The roller shall be weighed. The roller wheels shall be tested with a straight edge in order to detect untrue surfaces.

Badly worn bearings shall be replaced before the roller is used as a

defective roller will cause a wavy and untrue surface.

There shall be a positive bond between binder and top.

These are a few of the many details that must be constantly emphasized in asphaltic work.

Asphaltic Cement.—Our asphaltic concrete is of the familiar fine graded type having the following composition:

	Per Cent
Bitumen	5.5 to 7.5
Aggregate passing 200 mesh sieve	8.0 to 12.0
Aggregate passing 80 mesh sieve	6.0 to 15.0
Aggregate passing 40 mesh sieve	10.0 to 20.0
Aggregate passing 10 mesh sieve	10.0 to 20.0
Aggregate passing 3/8" screen	15.0 to 30.0
Aggregate passing 5/8" screen	5.0 to 20.0
Aggregate passing 3/4" screen	5 to 15.0

Screen: Circular openings.

The coarse aggregate used in the asphaltic concrete is slag as we have found this to be the most suitable of our local materials. We have many miles of slag asphaltic concrete which have given excellent service under heavy traffic for 10 to 15 years.

Chemical Treatment at Kansas City

Method of Water Purification at City Plant Outlined

By GEO. F. GILKISON
Chief Chemist, Water Department, Kansas City, Mo.

THE Kansas City, Mo., water department takes its supply from the Missouri River. This is a highly polluted surface supply, carrying a large amount of suspended matter.

Suspended Matter.—The suspended matter in the Missouri River varies over a very wide range, both with regard parts per million and coefficient of fineness. The turbidity of this stream varies from 15 parts per million in the winter, when the river is frozen over, to 18,000 parts per million in the spring, when the ice breaks up. The coefficient of fineness of suspended matter varies from 0.8 to 1.5, based on the A. P. H. A. standard.

Dissolved Solids.—The concentration of dissolved solids also fluctuates, varying from 300 parts per million in the spring when the river is high, due to snow water from the upper watershed and spring rains over the lower portion, to 540 parts per million when the river is at its lowest level in the winter. The Missouri River watershed covers approximately 430,360 square miles.

Color.—The Missouri River carries very little dissolved coloring matter, and at no time of the year is it a factor in computing the required chemical dose.

Hardness.—Ours is a comparably hard surface supply. The total hardness varies from 148 parts per million to 296 parts per million, expressed in terms of calcium carbonate. The average total hardness for the past year was 219 parts per million, of which 148 parts per million were due to calcium and magnesium bicarbonate, and 70 parts per million to calcium and magnesium sulphates.

B. Coli Index.—The B. Coli index of the Missouri River is very high at Kansas City, ranging from 50 per 100 c.c. to 100,000 per 100 c.c. completely confirmed.

Industrial Waste.—This division is indeed fortunate that, with all the industrial waste being discharged in the Missouri River, none of them, to date, had directly or indirectly interfered with our purification process. The characteristic odor and taste of chlorine, that you have doubtlessly all noticed in our city water supply, cannot truthfully be charged to industrial waste, but is the direct result of trying to maintain open storage basins in our industrial districts.

Chemical Treatment.—The chemical treatment at Kansas City consists of presedimentation, followed by coagulation with alum and lime, and sterilization with liquid chlorine.

Presedimentation.—With a raw supply carrying as high as 18,000 parts per million turbidity, it necessarily follows that presedimentation is an important step in purification here. At the Quindaro Purification Works the raw water is pumped into a 4,750,000 gal. basin, known as the horseshoe basin, or basin No. 1. It flows from this basin into basin No. 2 over a weir, in front of which is a stilling baffle. This basin has a capacity of 14,250,000 gal., making a total of 19,000,000, which is 4½ hours retention, based on 100,000,000 gal. daily pumpage. These basins are flushed regularly, but nevertheless they soon fill up with sludge, necessitating their being cut out of service and washed. Three hundred and thirty thousand six hundred and sixty-five tons of suspended solids were removed from the water in the Quindaro basins last year, 298,241 tons of which were removed in the preliminary basins, that is, 90 per cent of the basin load was carried by the preliminary basins. At the North Kansas City Purification Works we have four 4,000,000 gal. circular preliminary basins equipped with Dorr mechanical clarifiers. This gives four hours' retention, based on 100,000,000 gal. daily pumpage. This equipment provides for the continuous removal of the sludge, and eliminates the necessity of cutting units out of service for washing. The new North Kansas City Purification Works have been in service but a short time, and have been operating much below rated capacity. For this reason no attempt will be made to quote efficiency at this plant.

Application of Chemicals.—At the Quindaro plant the alum and lime are applied to the water through perforated lines as it passes over No. 2 weir; that is, as it passes out of the presedimentation basin. The water then enters a short mixing chamber, with a retention period not exceeding one minute. It then enters the coagulation basins, where it remains 17 3/10 hours, based on 100,000,000 gal. daily pumpage. It is chlorinated as it leaves these basins, and is pumped to the distribution station. No filters are provided at the Quindaro Purification Works. The average raw water turbidity for the past year was 3,100 parts per million, and the delivered water 10 parts per million, or an average of 99.68 per cent removal by sedimentation and coagulation alone.

Approximately 5,000,000 lb. of alum was used by the water department last year, all of which was manufactured by the department. The total cost of manufacturing alum for the past year was $16.22 per ton, delivered to the storage bin. The dose of alum varied from 4.26 grains per gallon to 0.58 grains per gallon, the average over the year being 1.67 grains per gallon. The lime used was lump quick lime, containing an average of 92 per cent water soluble calcium oxide. The dose used varied from 2.33 grains per gallon to 0.29 grains per gallon, the average for the year being 0.84 grains per gallon.

It will be noticed that the dose of lime is approximately one-half that of alum. This is the ratio we use most of the year. With an average hardness of 219 parts per million, it seems the addition of lime, purely for aiding coagulation, would be unnecessary, but experience has shown us that a much smaller dose of alum may be used, if approximately one part of lime is used to two parts of alum.

Chemical Cost.—The chemical cost of purification for the past year was $2.94 per million gallons, delivered to the city. This is the cost of chemicals alone, and does not include handling cost.

In view of the marked contrast in methods and equipment at the Quindaro and North Kansas City Purification Works, it is indeed unfortunate that enough operating data on the new plant is not at hand for comparison of efficiency and cost, but it is impossible to compute the efficiency of a hundred million gallon daily plant from the results obtained by operating it at one-fourth rated capacity.

Acknowledgment.—The foregoing paper was presented at the recent meeting of the Missouri Valley Section of the American Water Works Association.

The Sewage Treatment Plant of the Bloomington and Normal Sanitary District

How Two Illinois Cities Solved Their Sewage Disposal Problem

By CHARLES CARROLL BROWN
Associate Editor, Municipal News and Water Works

IN the earlier sanitary history of Bloomington, Ill., when it was perhaps half its present size, combined sewers were built, some of them by engineers who had the idea that open joints were preferable for such sewers, although the soil is the usual Illinois clayey loam with an occasional lense of more porous material. Perhaps as a consequence, straight grades were not thought to be necessary and it was reported that there were long pools of standing sewage in the system during periods of dry weather. The consequence of such pools was very evident at the untrapped storm water inlets and such manholes as have perforated covers. One engineer tried to cure the evil by inventing what he called a stench trap, which was a cast iron plate over a rectangular channel in the gutter at the catch-basin, with flap at each inlet from the gutter. The plate served as a gutter crossing for foot passengers at a street corner and the flaps were supposed to serve to retain the odorous gases in the sewer system. It is needless to say that the refuse brought to the catch basins by storm water propped open the flaps so that the neighbors complained bitterly of their inability to occupy their front porches on warm summer evenings.

In the years that have passed repairs to many sewers have removed some standing pools but that there are still some left is evidenced by the odors still given off at times through the untrapped storm sewer inlets, and by the dark color of the sewage delivered at the new sewage disposal plant, which was put in operation early last summer.

The Situation at Bloomington.—Bloomington and Normal are twin cities on the same drainage watershed and when sewerage and drainage conditions became troublesome in Bloomington it was manifestly unjust to put the whole cost of the main drainage system on the former city, through which Normal had its only practicable outlet. The situation was particularly troublesome to Bloomington because its water supply was obtained from wells in strata of porous material in the narrow drainage valley formed at and below the junction of two creeks which are the surface water drains and to some extent the underground water drains of Normal and of a considerable portion of Bloomington. These porous strata are at different depths and furnished various qualities of water, but those furnishing the best water were so near the surface that they were in danger of pollution by the slowly increasing sewerage system of Normal, whose only outlet is the stream mentioned.

Until 1917, however, nothing could be done officially to remedy conditions as to drainage and these two cities were among those active in securing the enactment by the legislature of that year of the Sanitary District Law of Illinois.

Formation of Sanitary District.—The Bloomington and Normal Sanitary District was established under this law in 1919 as the result of a vote of the taxpayers in the proposed district and much strenuous work by progressive citizens having the welfare of the cities at heart, and backed by the efforts of the State Department of Health with its experts, and others. The Trustees elected are John W. Harber and John J. Condon of Bloomington and W. W. McKnight of Normal, outstanding citizens of the district, having the full confidence of their constituents.

A preliminary study of the water pollution, sewerage and drainage problems of the cities was made by a well-known firm of engineers, which offered a full and promising solution for all of them but seems to have been more expensive than the citizens were willing to pay for.

The commissioners of the sanitary district took up the sewerage problem separately and now have their solution of it in what may be termed the trial stage of operation, and promising to be equal to others of the same sort under the same conditions, if not superior in some respects. They have done some necessary things toward the proper control of the surface drainage of the district and have attacked the problem of separating the sewage from the storm drainage in the existing combined sewers as well as by means of separate systems of storm drains and sanitary sewers in the newer parts of the cities.

The water supply problem is being attacked by a corporation formed by public spirited citizens who propose to secure a surface water supply, the cost to be borne by a bond issue of the corporation which will ultimately be taken up by the payment of rentals by the city and by the profits on water rates when the water works will become the property of the city. In this case the City of Bloomington will be the business operator and Normal will, if it chooses, become a wholesale customer, retailing water to its own citizens.

Design of the Plant.—A bond issue of $700,000 by the Sanitary District was voted in October, 1925, after some campaigning, with which to build the proposed sewage treatment plant and other works required in connection with it. Taylor and Woltman were selected as engineers, the former being a local engineer and the latter a young man of considerable experience in sewerage operations. They were given full opportunity to study their problems and to secure all the data thought necessary to make application of well established methods to the particular conditions at Bloomington. The result is a standard design including bar screens, grit chambers, pumping sewage up 25 feet through a Venturi meter to Imhoff-type primary settling tanks with upper story flow-through chambers dropping the settlings into digestion tanks or chambers below from which gases arise in the gas chambers to escape into the air or to be gathered and burned; sludge drying beds, dosing chambers distributing clarified sewage to sprinkling filters with broken stone as filtering material, secondary settling basin, small sludge pumping plant to pump sludge from secondary basin to primary sludge digestion chambers, the fully clarified effluent discharging through an improved concrete lined creek channel to Sugar Creek, a larger and as yet unimproved channel. The system need not be described in detail at this time except as to features which are peculiar to this plant and show how modern engineers modify standard practice to fit special conditions.

The accompanying diagram shows the direct flow of sewage and sludge by perhaps the shortest journey possible, entering from the north and flowing round the plant in the direction of the hands of a watch so that the treated and clarified sewage from the secondary settling basin enters the improved creek channel at a point opposite the short by-pass from the screen chamber; and the dried sludge is found at the south side of the plant at the most convenient place for removal, whether used for filling low ground about the plant or sold to farmers and removed by way of the road, which, by

Layout of the Sewage Treatment Plant of the Bloomington and Normal Sanitary District, Illinois

the way, is about 15 feet above the level of the sludge beds.

The plans for the pumping stations bear the name of Associates of J. L. Pillsbury, a firm of architects in Bloomington, continuing the notable work of the deceased founder of the firm. Stanley Pinel, who was employed by Taylor and Woltman on the preparation of the plans became later the resident engineer on construction and since putting the plant in operation has been superintending it to determine how closely it approaches to the efficiency for which it was designed. A visit during the summer showed satisfactory action and the test under the more difficult conditions of the winter season is now under way. J. L. Simmons Company of Bloomington are the contractors, who have recently finished the cleaning up and adjustment of the plant under Mr. Pinel's direction.

Sewage Collection System.—The area of the Bloomington and Normal Sanitary District is about 8.5 miles, comprising practically all of the two cities. There are about 80 miles of sewers, carrying from 6 inches to 96 inches diameter. These sewers discharged into Sugar Creek in its passage through the two cities, through nine outlets. An intercepting sewer 2 miles long was built to take the ordinary flow of sewage and the first storm water washings from the streets. It taps all the outlets, the upper end taking the sewage from Normal in a 27-in. pipe, which increases in size as the various outlets are reached until it becomes a 51-in. vitrified segmental block sewer, which enters the disposal plant from the north. A dam was built across the invert of each of the combined sewers, high enough to turn the sewage and the proper proportion of storm water into the intercepting sewer, all flow in excess overflowing into Sugar Creek. It is believed that the dilution of sewage by storm water, thus provided for, will be sufficient to prevent any nuisance in Sugar Creek. If not, change in height of dam in sewer can be made to insure greater dilution as the amount of sewage carried by such sewer may increase in the future.

The new plant is designed for a population of 54,000 people, fully twice the population now actually connected with the system, and by proper operation can handle considerable overload, including such as may come when the storm flow is at its peak. There is plenty of room, and the plans provide for doubling the capacity of the plant as constructed, by duplicating the settling tanks, sludge beds and sprinkling filters, on favorable ground adjoining the present respective structures. Space has been provided in the buildings for the necessary additions to pumping capacity.

Location of Treatment Plant.—As is so often necessary, the plant is located on a low flat alongside which the main drainage outlet of the cities runs, Sugar Creek, and through which a small stream runs draining a small area occupied in part by a thinly settled section of the city and in part by garden areas. The channel of this small stream has been improved with concrete bottom and walls for about 500 ft. to the point of entrance into it of the outlet from the secondary settling tank, and the bypass of the unpurified sewage in case of necessity. For about 250 ft. in the higher ground within the plant the creek is covered, the shortness of this covered section showing economy in design. Above this the channel is open up to the east boundary of the city property. The low ground within the property is protected by levees from overflow by storm-swelled Sugar Creek until it can be filled by the odorless sludge or acceptable refuse and waste dirt from outside excavations. The extension of the plant shown in the plans, will ultimately reduce the suggested filling to a reasonably small amount.

The 30-in. cast iron main, through which the sewage from the grit chambers is pumped up to the primary settling tanks, crosses above the covered channel of the small stream and is the only instance of the crossing of main lines of flow, in the design. There are, of course, some crossings by water pipes and drain tile.

The soil on the lower portions of the site is 4 to 10 ft. of black loam underlaid bywater bearing materials, mixtures in varying proportions of brown-black soil, yellow clay, sand and gravel, some of the 35-foot drill holes showing blue or other firm clay. The primary settling tanks are set on sloping bank with difference of elevations of about 7 feet, putting the bottom of the excavation for the tanks not far under the water level and some 4 ft. higher than the bottom of the secondary settling tank and the pump-house. The other structures are on or near the surface of the ground. The small area of the pump-house required excavation 18 ft. below the surface of the ground, the maximum of any structure in the plant. The advantage of delivery of the sewage to the pumps at a level up to 10 ft. above the pump center. The location of the structure is such as to have reduced the cost of excavation close to a minimum.

Motor driven centrifugal pumps of 4, 4, and 6 million gallons per day capacity have been installed and there is room for another when future demands require it. The 51-in. inlet from the grit chambers enters the pump well near its top and the outlet pumping main leaves the station at about the same elevation. All drainage in and about the house enters a 36-in. sump in the corner of the pump room under the stairway and is removed therefrom by an automatic electric bilge pump.

Flow of Sewage Through Plant.—The 30 in. pumping main raises the sewage about 25 ft. and delivers it at one corner of the battery and six primary settling tanks, each 28 ft. 4 in. wide and 90 ft. long and 29 ft. 6 in. to bottom of hoppers. The sewage may be turned to flow in a channel along one end of the tanks or along the side of the end tank and then along the other end of the tanks, thus giving ready reversal of flow through the tanks. The width of this channel decreases as each inlet to a tank is passed, from 3 ft. at the entrance to 18 in. at the farther end. Sewage is let into each flow through chamber by a 12 in. pipe leaving the bottom of the inlet channel and discharging at a depth of about 4 ft. below the water surface, depending on the position of the adjustable outlet weirs of the tanks. Each inlet pipe is controlled by a circular sluice gate over its end, operated from stand on walk-way above.

Between these inlet channels and the tanks are located the outlet channels into which the settled sewage flows over adjustable weirs 6 ft. long. These outlet channels increase in size in the direction that the inlet channels decrease from a width of 2 ft. to one of 4 ft. The inlet and outlet channels together occupy a bracket on the outside wall of the tanks, which is 7 ft. 10 in. wide overall.

Between the double walls of each alternate pair of tanks is a space partly filled with sand on which rests a concrete channel into which flows the sludge brought up from the tank hoppers by cast iron pipes and from which by pipes and channels it reaches the sludge drying beds and is distributed over them. The valves opening the sludge pipes are operated by hand wheels on the sidewalk above. This sludge channel should be very easy to clean after each drawing of sludge.

Among other items deserving special mention as convenient accessories to the plant are the full supply of water under pressure from the water supply pump house shown on the sketch, and the elevated tank so that every part of the plant can be kept clean and can be washed out thoroughly in case of stoppage by anything but ice. This winter will be a better criticism of the ability of the sewage to resist the fall of the thermometer than any which can be written at this time.

Glass Roof Over Sludge Drying Beds.—The greenhouse roof over the first six of the 20 sludge drying beds, and the possibility of supplying additional heat to that of the sewage and the sun, if necessary, will take care of a situation which might give considerable trouble without these provisions if the best action of the settling basins requires drawing of sludge at any time during the winter. Unless the weather is too erratic, it should be possible to make drafts of sludge from the tanks at times when the weather conditions are favorable to rapid drying of the sludge under glass cover, and not otherwise. A provision of grooves in the walls of the gas-chambers of the settling tanks has

been made so that if desired covers can be put on which will slope to a central tube leading the escaping gases to storage tanks (not yet provided for) to use as fuel for any desired purpose. There will be plenty of use for heat about the plant, for the best results in this case as well as for other purposes. Proper treatment promises so far to prevent the formation of odorous gases about the plant or to decompose them before letting them go, in case their conservation for use as fuel is not decided upon.

The dosing tanks are automatic, four in number, alternating in pairs, each pair serving one of the two sets of sprinkling filter beds. The 30 in. delivery pipes through the gallery between the filter beds reduce in size as each branch to a sprinkler lead is passed until they reach 16 in. diameter at the farther end. The branches through the beds are each of 8 inches diameter with standard ⅞ in. orifice sewage nozzles 14 ft. apart, the first being 11 ft. from the central gallery and the last being a half-nozzle, 4 ft. from outer gallery and just before the 8 in. pipe reduces to a 4 in. connection with outlet and with wash-water pipe.

The collection channels on the bottom of the filters are in the concrete base, trapezoidal in section, 3 in. deep by 9 in. in top width. They are covered by bricks, 1½ by 4 by 13 in., set on edge and alternating so as to leave 1½ by 13 in. spaces through which the water percolating through the stone reaches the channels.

The Specifications.—The brevity of the engineering specifications deserves attention. The specifications for materials occupy 7 pages of ordinary textbook size, printed in the large, 11-point type common to such books. They 22 items or paragraphs, liberally spaced on the pages. Sewer pipe and blocks, concrete materials in detail, steel for various uses, cast iron, lumber, expansion joints, valves and special appurtenances are all covered. The specifications for construction are equally brief and comprehensive. Excavation, backfilling, laying sewer, block or pipe, water pipe, concrete, placing valves, gates, etc., in full detail occupy not quite 19 similar pages, covering work done at unit prices. Such items as grit chamber, the engineering portion of the pumping station, primary settling tanks, sludge drying beds, dosing tanks, sprinkling filters, secondary tank, sludge-pumping station and appurtenances, paid for in lump sums, are fully covered in 22 pages and 4 additional pages cover some special work, some paid for in lump sums and some by unit prices. In addition are the usual General Conditions, and papers pertinent to advertising, bidding, signing the contract and bonds. Inspection indicates that results equal to those obtained under far more extended specifications have been obtained.

The Albany, N. Y., Typhoid Fever Damage Suits

The Appellate Division of the Supreme Court of New York State has unanimously the action of a supreme court jury which in November, 1926, awarded $2,000 to a minor and $1,000 to his father on the claim that the patient contracted typhoid fever from the drinking water of the city.

In April, 1924, Mr. Charles R. Cox, Assistant Sanitarian, Division of Sanitation, State Department of Health, Albany, N. Y., comments in the case as follows in the November Journal of the American Water Works Association.

The water supply of the city of Albany is secured from the Hudson River at a point about 8,000 ft. north of the main portion of the city. An elaborate water purification plant is utilized to treat the heavily polluted Hudson River water. This plant consists of aerators, coagulation basins, rapid sand filters, secondary aerators, slow sand filters and chlorination equipment. The chlorinated water from the clear well flows to a high pressure pumping station about 8,000 ft. south of the filtration plant through a conduit.

The filtration plant is under expert supervision and water of a safe sanitary quality has been discharged into the clear well. The conduit conducting the effluent from this clear well to the high pressure pumping station, however, consists of about 8,000 ft. of steel piping 48 in. in diameter, most of which is covered with concrete. The steel conduit had been in use for over 20 years and the walls had become seriously corroded at points. This conduit is laid for the most part under the bed of the abandoned Erie Canal, which normally contains about 1 ft. of water due to local drainage. In April, 1924, a flood of the Mohawk and Hudson Rivers occurred and the abandoned Erie Canal was flooded to a depth of from 6 to 8 ft. with polluted Mohawk River water.

During April, 1924, there was a sudden increase in the prevalence of typhoid fever in the city of Albany, and during this period the tap water in the city contained increasing numbers of colon bacilli, as determined by bacteriological examination in the State Laboratory.

Suit was brought against the city of Albany by the parent of one of the patients who contracted typhoid fever at this time. A decision in favor of the plaintiff was handed down by the Supreme Court in 1926, which decision was appealed to the Appellate Division of the Supreme Court in May, 1928. The important portions of the opinion of the presiding justice of the Appellate Division are quoted below:

> It is claimed that the disease had its inception in unwholesome water furnished by the city, and this condition arose through the negligence of those in charge of the water system in failing to purify the water delivered to consumers; and that the authorities neglected to give warning, although they had notice that dangers existed. . . .
>
> Beginning on April 7, the water was tested at the state laboratory by and under the supervision of Dr. Wachter, a chemist in the Division of Laboratories and Research of the State Department of Health. These tests were made from the tap which was on the same system as that furnishing water to plaintiff's family. On nearly every day between the 7th and the 23d of April, colon bacilli were found in increasing numbers, indicating some definite source of pollution not eliminated by the filtration. About this time there was a sudden increase in gastro-intestinal diseases in the city. The officials in charge of the water department had notice of the defective condition of the conduit, the sudden pollution of the water, and of the outbreak of diseases traceable to impure water, but the warnings were ignored. It was a time for prompt and decisive action. There were two possible sources of contamination—one by impure water passing the filters into the well; the other by introduction of polluted water into the conduit. The exercise of vigilance would have led to discovery of the dangerous condition, and reasonable diligence would have provided the remedy. It was possible by greater chlorination before the water went into the clear water well, to eliminate all dangerous bacilli which had passed the filter; and there was a chlorination plant at the Quackenbush St. pumping station which would have removed the new pollution occurring in the conduit, but this was not put in use, at least during the first ten days in April. Common prudence would have suggested a notice to citizens that the water had become polluted, and a recommendation that all water intended for human consumption should be boiled. But no preventive measures were taken until an epidemic had broken out. . . .
>
> To insist that the plaintiff must establish that the infection came from the city water by positive proof, would be to require an impossibility. It is sufficient if it is shown by the best evidence available that the bacilli were introduced into his system by means of the city water, so that the jury may by reasonable inference reach a conclusion to that eeffct. This is not speculation, but a process of logical deduction. . . .
>
> The plaintiff gave proof excluding other sources of infection. The defendant's counsel in argument merely suggests that there are other possible sources, but there was no sufficient proof on its part of their presence or of the probability that such causes intervened to furnish the origin of the plaintiff's disease. The epidemic at this particular time, including such a large number of cases, would under the circumstances shown, indicate a common origin. . . .

Particular attention is called to the next to the last paragraph above, since it is not unusual in cases of this kind for attorneys for the defense to attempt to make the plaintiff furnish positive proof that the infection came from the water, which, as the court justly says, is an impossibility.

Since this outbreak of typhoid fever, great care has been exercised in maintaining 0.20 to 0.25 p.p.m. residual chlorine in the tap water in the city about ¾-mile from the point of application, although this practice has naturally resulted in the delivery of water with a chlorine taste at frequent intervals. The city authorities have installed a booster pumping station at the filtration plant, which places the repaired conduit under a positive pressure at all times, so that any appreciable leakage would be of filtered water outward rather than polluted surface water inward. The water passing through the conduit is again chlorinated at the high pressure pumping station.

The steel conduit is being replaced by cast iron pipe at considerable expense. This pipe line will be used until the new water supply from the Catskill Mountains is completed, which will permit the abandonment of the Hudson River supply, and the use of the cast iron pipe as a main feeder for the northern portion of the city of Albany.

The Function of Aeration in Water Purification

A Paper at 10th Texas Water Works Short School

By N. T. VEACH
Consulting Engineer, Kansas City, Mo.

AERATION has been employed in water works practice since its inception, as is evidenced by the cascades and fountains, commonly found in water systems, both ancient and modern. There is no evidence, however, that the fountains or cascades used previous to the early eighties were installed for any reason other than that of beauty, although it is possible that reduction of odors may have been noticed in some cases.

The use of aeration as an adjunct to water purification in this country dates back to 1883, when its use was investigated by Leeds in connection with water purification studies at Philadelphia, and, since that time, aeration in its many aspects has been studied by numerous investigators. Many technical articles on aeration have been published since 1900, and a study of this subject leaves no doubt of the fact that, while aeration is established as an important aid in water purification, it is not, in any sense, a "cure-all," or a complete treatment for water troubles, and unless used properly, may be an actual detriment to the water.

What Simple Aerators Will Do.—The investigations on aeration have proved beyond a doubt that, with simple aerators:

1. Oxygen may be added to water to the point of saturation.

2. Carbon dioxide may be largely, but not completely, removed.

3. Odors and tastes, when due to gaseous products of organic decomposition, may be removed to some extent, but when due to products of organic decomposition in solution, the effect is negligible.

4. Odors and tastes due to coal tar, phenol, oil refinery and similar wastes, are affected little.

5. Odors and tastes due to overchlorination may be satisfactorily removed.

6. Odors due to hydrogen sulphide are easily eliminated.

7. The actual oxidation of organic matter in solution or suspension is negligible, but some inorganic compounds, notably those of iron and manganese, are largely, but not completely, oxidized.

8. The "aggressiveness" or corrosiveness of some waters, usually "soft" or "peaty" waters, is increased by addition of oxygen, but that of surface water commonly encountered in the Middle West, is not appreciably affected.

9. The economy and effectiveness of treatment with the ordinary coagulants is, with few exceptions, increased.

10. The bacterial content of the water is often reduced appreciably.

When Aeration Should Be Considered.—From the foregoing conclusions it is evident that the water works man must consider aeration when designing or operating a water plant, to treat:

1. Waters which contain iron or manganese held in solution by carbon dioxide.

2. Waters which contain carbon dioxide and which are to be softened, or which, due to their carbon dioxide content, are "aggressive."

3. Waters from algae-laden reservoirs or reservoirs upon which ice forms.

4. Some rivers which are hard to treat with ordinary coagulants, or which, during low water, approach the conditions found in an impounding reservoir.

Several questions which must be answered for each individual case and which, unfortunately, can be answered only in a general way, with plenty of allowance for numerous exceptions, are:

1. How complete is the aeration required?

2. Is aeration economical, in view of the fact that carbon dioxide can be removed by the use of approximately 15 lb. of lime (or an equivalent amount of soda ash), per million gallons of water per part per million of CO_2?

3. At what stage in the treatment-process should the water be aerated?

4. Which of the numerous types of aerators should be used?

Usually, if aeration is needed at all, it should be carried through to an extent which will saturate a water which is originally devoid of oxygen. If carbon-dioxide removal is the object, this extent of aeration will ordinarily leave not more than 5 parts per million in solution when highly-charged waters are treated, and will remove, approximately, 50 per cent when the original amount of carbon dioxide is from 5 to 10 parts per million. Further aeration will, of course, effect a more complete removal, but at a rate so slow that it is out of the question from an economic standpoint.

If removal of odors is the object, this extent of aeration will permit a thorough "sweeping out" of the gases which cause the trouble, and, to obtain further removal of odors, actual oxidation of the organic matter which causes them must ordinarily take place. This will require a period of aeration much longer than that obtainable in the usual type of aerator, and, in addition, the aeration to be effective must take place in the presence of certain "oxidizing" or nitrifying organisms. This is the underlying principle of the "activated-sludge" process of sewage disposal.

The results obtainable by various types of aerators will be discussed below, but, for ordinary waters, an additional head of 8 ft. will be sufficient to provide this amount of aeration.

The economy of aeration can be determined by balancing the cost of the additional head required against the cost of additional lime or soda-ash treatment. If softening or coagulation is to be practiced, as is usually the case, this additional cost of chemicals is all that need be considered.

At Albuquerque, N. Mex., the city water, obtained from wells, has approximately 6 parts per million of carbon dioxide in solution. An iron-removal plant with facilities for feeding lime is to be built. The cost of pumping the water against an additional head of 8 ft. amounts to 83 ct. per million gallons, while the additional cost of lime necessary to remove the 3 parts per million of carbon dioxide which an aerator can be expected to remove is only 45 ct. per million gallons. Generally speaking, an aerator cannot be economically justified for waters which contain less than 10 parts per million of carbon dioxide unless the elimination of odors enters into the problem, in which case aeration is, of course, necessary.

Aerators have been used successfully before and after sedimentation, and, in several recent installations, the effluent from sand filters has been aerated before storage. Ordinary purification-plant design, however, usually precludes aeration at more than one location, and, for the customary water encountered in the central part of the country, the practice of aerating the raw water before further treatment is well established and seemingly satisfactory.

At Moberly, Mo., water is aerated immediately after the addition of chemicals, with rather poor results, due to

the fact that the partially formed floc is broken up by the action of the aerator. Pirnie reports a case in Danville, Va., where a reduction in chemical dose was made possible by aeration for removal of CO_2 immediately after the addition of alum.

The selection of the proper type aerator for use is, of course, a matter to be determined for each case, to fit the local conditions, of head, quality of water and treatment-process.

The aeration devices commonly used in water purification may be divided into general classses as follows:

1. Air-lift pumps.
2. Injection aerators in which air is blown into the water.
3. Gravity aerators in which the water flows out of riser pipes, flows in thin sheets over weirs, cascades, or inclined planes, drips through perforated pans, or percolates through beds of suitable ballast.
4. Fountains, where the water is sprayed into the air through nozzles.

Air-Lift.—Air-lift apparatus for water pumping from deep wells has been in use for years and is well known, but its aerating effect on water has not been given much consideration until fairly recently.

Donaldson, at Memphis, found that air-lift pumping reduced the carbon dioxide in the local well water from 107 to 30 parts per million.

Air-lift equipment coupled with simple riser-pipe inlets to storage basins, at Pittsburg, Kan., has been effective in removing hydrogen suphide odors.

Injection Aerators.—Aerators of the injection type have been used for water in a few instances, but, at the present time, this practice is largely limited to aeration of sewage, with the purpose of continuous aeration at a relatively high rate in the presence of nitrifying organisms, and for a period long enough for actual oxidation of organic matter to take place. This requires from four to six hours, while the ordinary aerator as used in water practice, operates for a period of only one or two seconds.

At Hackensack, N. J., a substantial reduction has been effected by air blown through the stagnant layers of a reservoir by means of a gridiron system of small pipes, and at Essex, Ont., air applied at the rate of 5 cu. ft. per 100 gal. through a single filter plate 12 in. square, increased the dissolved oxygen from 2.0 to 4.5 cc. per liter, reduced the carbon dioxide from 6.6 to 3.9 parts per million and completely removed, approximately, 10 parts per million of hydrogen sulphide. Aeration, in this case, was primarily for the purpose of reducing the necessary rate of chlorine feed, which, due to absorption by hydrogen sulphide, was 40 parts per million in the unaerated water, to 3 parts per million in the aerated water. Aeration, in this instance, effected a net saving of 50 lb. of chlorine per day and presents a rather novel and interesting use for this treatment.

The principal objection to this form of aeration is, of course, the fact that the air blown through the water precludes the use of valuable basin-capacity for coagulation or settling, and the cost of providing additional tanks for this purpose is, usually, out of the question from a standpoint of economy. However, where head is not available, or in cold climates, this type of aerator may be used to advantage.

Gravity Aerators.—Probably most of the aerators now in use are of the gravity type, which general type, as stated above, includes riffle-boards, riser-pipes, cascades, spilling-weirs, coke-beds, etc.

This is probably due, partially, to the relatively low head required and partially due to the fact that, for given capacities, gravity aerators can be constructed at a cost lower than that of other types.

Inclined planes studded with riffle-plates are used at Cambridge, Mass.; Plattsmouth, Nebr.; Norristown, Pa., and several other plants.

At Cambridge, 14 million gallons per day of filter-effluent is treated on riffle-boards which cover 923 sq. ft. and which are set in a slope of 3 ft., horizontal, to 8 ft. vertical.

From 20 to 30 per cent of carbon dioxide is removed by this process, which represents a loading of, approximately, 10 gal. per square foot per minute.

At Portsmouth, Va., four steps each 13 in. high are used, and about 40 per cent of CO_2 is removed.

In tests made at Memphis on the aeration afforded by allowing water to flow evenly over an inclined walkway 10 ft. wide, 28 ft. long, with a drop of 2 ft. in length, 46 per cent of carbon dioxide was removed from water which originally contained 28 parts per million.

At Excelsior Springs, Mo., an aerator of the multiple-pan type has been in use for 12 years. Water enters this aerator through a riser-pipe, which terminates in a steel pan 7 ft. wide, 20 ft. long and 4 in. deep. From the sides of this pan the water spills successively into two pans 4 ft. wide, thence into four pans 2 ft. wide and thence into 8 pans each 1 ft. wide. The four tiers of pans are set 1 ft. 9 in. apart, vertically, and the total drop from the upper pan to the floor of the collector is 7 ft. 6 in. The total area of the pans is 620 sq. ft. and the total weir length is 600 lin. ft. When operated at a rate of 512 gal. per minute, approximately 68 per cent of the CO_2 was removed from water with an original content of 85 parts per million.

Multiple-pan aerators of this type are in successful use at Topeka, Kan.; Lawrence, Kan., and a number of other places, and recently, at the suggestion of the Kansas Board of Health, flat slabs of lumber or concrete have been used in place of the pans, at a considerable saving in cost, and no decrease in efficiency.

An aerator of the multiple-pan type, but with perforations in the pan bottom, was constructed at Superior, Wis., in 1901, and gave excellent results, as did one of a similar plan built at Winchester, Ky., about the same time. Most of the early aerators used as an aid to water purification were installed for the purpose of iron removal and a common expedient was to allow the water to percolate through beds of coke coal or other ballast.

Carbon dioxide is removed to some extent by this process, since the water flows in thin films over the ballast and the oxides of iron on the ballast itself acts as a catalyzer in the oxidation of the iron. This process is still in use in many plants, but generally, in connection with pre-aerators, settling basins and filters, and experience has shown that, for complete removal of iron and manganese, lime or soda-ash treatment must be included in the process.

Fountain Aerators.—Aerators which employ jets or sprays seem to be more generally used now than heretofore, probably due largely to the development in recent years of nozzles, which will operate efficiently at low heads. Satisfactory results are obtained at Charleston, S. C., with a head of 4.5 ft., and at Sacramento, Calif., a "floating" type of nozzle which will operate at still lower heads has been developed. Ordinary nozzles require heads of from 15 ft. upward.

Another reason, and a potent one, for the selection of the fountain-type of aerators, is the opportunity offered for "dressing up" the plant. As Mahlie very truthfully says in his article on "Aeration in Water Purification," "a ½-in. pipe spraying water in the air over a pool, apparently satisfies the general public more than a 6-in. line discharging sterilized filtered water beneath the surface."

Where head is available for fair-sized water streams, extremely sightly arrangement of nozzles can be made, as evidenced by recent installations at Denver, Colo.; Oakland, Calif., and elsewhere.

Exclusive of the question of head, spray nozzles offer the most efficient method of aeration, and experience indicates that the nozzles which throw a whirling, fine spray are the most efficient.

Donaldson's experiments at Memphis provide an excellent yardstick for determining the amount of aeration obtainable by different types of aerators.

He found that water which contained 28 parts per million of carbon dioxide, lost, approximately, 14 parts per million, or 50 per cent, on being discharged from a 2-in. riser-pipe and falling 5 ft., and that this rate was fairly constant while the flow varied from 40 to 110 gal. per minute. When an 18-in. cir-

cular splash table was placed 18 in. below the top of the riser-pipe 18 ppm. was removed at a discharge of 95 gal. per minute and 12 ppm. was removed when the discharge was 40 gal. per minute. When a pan 18 in. square, perforated with 211 holes, was placed 5 ft. above the receiving basin, a removal of from 14 to 17 parts per million of CO_2 was effected. Three 12-in. coke beds set with 12-in. openings between them, and a total vertical fall of 6 ft., effected a reduction of 21 parts per million at a loading of 70 gal. per square foot per minute, and of 24 parts per million when the loading was reduced to 10 gal. per square foot per minute.

Spray-nozzle experiments on the same water showed that it is possible to reduce the residual carbon dioxide to two or three parts per million with discharges of from 80 to 100 gal. per minute, and that they were more efficient than aerators of the gravity type.

It is interesting to note that in the case of Memphis, aerators of the gravity type and consisting of multiple pans of coke, were selected for construction, even though a greater efficiency was shown by the sprays.

Summary.—Results of tests on aerators of different types, operating under different heads on different waters, vary so greatly that no general conclusion can be made as to the effect any particular type of aerator will have on a given water, and one is forced to the conclusion that, for safety, design should be based on actual tests made under operating conditions on the water to be treated.

The efficiency of aeration in iron and manganese removal, odor removal, treatment for aggressiveness or corrosiveness, and as an aid to coagulation, is established, and like filtration or carbonation, aeration is a valuable tool, to be used in the proper place in the water-treatment plant.

Methods of Financing Extensions in Large Cities

A report compiled by the Municipal Reference Division of the Seattle Public Library for the Water Department of Seattle, Wash., shows that three methods of financing water main extensions were in use in the 33 cities of over 200,000 population in this country. The following extract from the report gives the information on these methods:

Assessment.—The costs of extensions are assessed against abutting property, in whole or in part, in the following cities:

Cincinnati. $1.50 to $2.50 per front foot according to pavement. This is estimated as one-half actual cost. Property on undedicated streets must pay all costs.

Cleveland. $2 per front foot, maximum charge. Corner lot assessed on one side only.

Columbus. Cost of 8-in. main or less with deductions for frontage supplied with water within 30 days (1924 information).

Detroit. 75 ct. per front foot. Corner lot assessed on one side only.

Los Angeles. District assessment bonds, or 80 ct. per front foot. If property is in excess of 200 ft. a deposit of 80 ct. per front foot on each side of street beyond 200 ft. is required. Deposit returned when new services are installed for other property fronting the mains, or at end of 5 years.

Milwaukee. Cost of 6-in. main. One-third of total frontage of corner lots exempt when main is laid on long side.

Minneapolis. One-half cost of 6-in. main. Corner lot assessed for long side; short side exempt up to 66 ft.

Omaha. Cost of 6-in. main. Two-thirds of side of corner lot exempt.

Philadelphia. $2 per front foot. One-third of one side of corner lot exempt, not to exceed 50 ft.

St. Paul. $1 per front foot payable in 10 yearly installments without interest. Short side of corner lot assessed up to 125 ft.

Seattle. Cost of not more than 8-in. main in residence district. Maximum charge $2.25 per front foot. Corner lots assessed for side on which building faces. Business districts assessed for cost of main necessary. Corner lots assessed on both sides.

Washington. $2 per front foot. 100 ft. exemption on corner lot.

Water Funds.—Cost of extensions are paid from the water funds in the following cities: Boston, Buffalo, Denver, Jersey City, Indianapolis (private company), Kansas City, Mo., New York, Oakland (private company), St. Louis and Toledo. (Information is of 1924 for Boston, Buffalo, Denver, Jersey City and Toledo.)

In the following cities costs are met from water funds with certain exceptions or provisions:

Akron. Assessment basis is used only in allotments where allotment company assumes and distributes the entire cost.

Baltimore. A deposit of $1.50 per linear foot is required but this is refunded to the extent of $100 per lot if a house is built within 10 years. Property owners must pay any extra costs due to street not being within 6 in. of established grade.

Chicago. An assessment on the cost of a 6-in., 8-in. or 12-in. main is made, but 90 per cent of the assessment is returned when a survey shows a revenue of 10 ct. per linear foot. This is generally within 5 years.

Louisville. If revenue does not justify the extension, property is assessed but a refund is made if revenue is sufficient within 5 years.

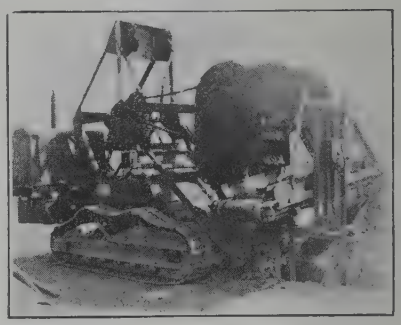
Portland. Six per cent revenue must be guaranteed.

Providence. Seven per cent revenue must be guaranteed for unaccepted streets (1924 information).

Ditching Machine Economical with Limited Trenching Program

The use of a light ditcher is often real ecomony for the community having as little as 12,000 lin. ft. of ditching to do in the course of the year. An interesting case has been recently reported that bears out this assertion.

During 1927, the City of Kalamazoo, Mich., operating a Barber-Greene vertical boom ditcher, dug 12,128 lin. ft. trench for 6 in., 8 in., and 24 in. water mains, reported the following cost data,



Light Ditcher Used in Kalamazoo, Cost Data on Which Are Given on This Page

as compared with costs of similar work by other methods done during the previous year:

	Per lin. ft., 6 in.	Per lin. ft., 8 in.
1926	$1.64	$2.73
1927	1.47	2.14

The actual costs of operating the machine for that year, showing the total and per lineal foot costs as given out by Earle E. Norman, Department of Public Utilities, were found to be as follows:

	Cost for 12,128 lin ft.	Cost per lin. ft.
Gasoline	$ 48.18	$0.00398
Oil	7.19	.000594
Grease	9.14	.000754
Repairs	119.49	.00994
Repairs, labor	64.38	.00538
Total operating cost	$ 248.38	$0.02065
Depreciation	831.64	.068
Total	$1,080.02	$0.08865

To these costs must be added moving costs of $5.28 per mile and a rental charge of 10 ct. per lin. ft. for the use of the machine, which charges were made in this instance.

While comparative costs are not available on the 24 in. main, the department has stated that while the estimate on a project for laying 24 in. main using other methods was $12,500, that the job was actually done in 1927 with this type of ditcher for a labor cost of $9,065.73 and a machine cost of $342.28, giving a total cost without material of $9,408.01, thus making a total saving of just over $3,000. At least $2,000 of this saving, it was stated, could be directly ascribed to the use of the machine.

Design Data For Open Gravity Type Rapid Sand Filters

Elementary Features Described at Texas Water Works School

By A. W. LIVINGSTON

E. W. Bacharach & Co., Consulting Engineers, Kansas City, Mo.

The writer will restrict his paper to design data pertaining only to the filter unit itself and more specifically to the open gravity type of rapid sand filter.

The original rapid sand filter unit was built circular in form, constructed out of wood or steel. Nowadays it is customary to construct such filters out of concrete and to build them rectangular in form. Some of the advantages gained by this are durability, elimination of waste space and the use of the concrete walls of the filters as a support for the building covering them. The rectangular shaped filter has many other advantages, chief among which is the fact that a more efficient underdrain and wash water distributing system can be adapted to it.

Filter Capacity.—For average conditions the capacity of a filter to be used for domestic supply is based upon a rate of flow of 2 gal. per minute for every square foot of sand bed area. In other words, if a certain filter is to have an output of 300 g.p.m., the area of the sand bed should be 150 sq. ft. If the filter is to be used for clarifying water, without regard to the removal of bacteria, its rate may be increased to three and sometimes as high as 4 gal. per minute per square foot of sand area. If, on the other hand, the filter must be designed to purify a highly contaminated water, or if the filter is to be used in connection with an existing mixing chamber, and settling basin yielding low efficiency, it would be advisable to increase the sand bed area so that the filter could be operated at a slower rate than the standard rate of 2 gal. per square foot of sand surface per minute.

After knowing the total capacity of filtered water in gallons per minute required to meet a particular case, it is only necessary to divide this sum by the rate at which the filters are to be operated in order to determine the total filter sand bed area. For example, if the plant is to have normal capacity of 700 g.p.m., and is to be operated at a rate of 2 gal. per square foot of filter sand surface per minute, the total sand area would be 350 ft.

Number of Filter Units.—The next step is to decide the number of filter units that the toal capacity is to be divided into. This is determined by size of plant, possibility for future extension, ground space available, economy in first cost, operating expenses, etc. Unless the filters are designed for an ample reserve capacity above the maximum requirement, it is advisable to build them in comparatively small units, so that when one or more are out of service for washing or repairs, the remainder may still be able to meet filtered water demand. On the other hand, if there are indications that the consumption of filtered water may rapidly increase after installation of the filter plant, it would be more economical to use larger filter units and have their total capacity considerably in excess of present requirements.

There is no fixed rule for determining the correct proportion between length and width of a filter unit. This depends upon capacity of filter, type of underdrain system to be used and other factors. As a general rule, the length of a filter should be from 10 per cent to 30 per cent greater than its width. This shortens the length of pipe gallery and operating floor, thereby reducing cost of pipe and the distance that the operator has to cover in order to manipulate the filter valves and devices. Moreover, wash water troughs and strainer systems can usually be better adapted to the long and narrow unit than to the short and wide filter or the absolutely square unit. For example, a filter unit having a capacity of 500,000 gal. per 24 hours is very frequently required, and unless adverse conditions obtain such a unit is usually built 15 ft. long by 12 ft. wide. As a result, patterns for the underdrain systems and wash water troughs have been made by all equipment manufacturers for this standard size. If the same sand area, namely, 180 sq. ft., were made up by designing a filter 20 ft. long by 9 ft. wide, it would make it difficult to arrange strainer system and wash trough for uniform distribution and would crowd the valves, valve stands, controller and other appurtenances.

Depth of Filter.—Most engineers require a total depth of sand and gravel of about 4 ft. In order to prevent the carrying away of the filter sand, the top of the wash troughs are placed about 2 ft. above the top of the filtering material or approximately 6 ft. above the bottom of the filter. As the level of the water on top of the filter varies to some extent in most plants, space should be provided above the wash troughs to take care of this variation. Usually about 2 ft. is allowed for this so that the average filter has a total inside depth of about 8 ft. This depth may be increased or diminished within certain limits if necessary, but these limits are determined by local conditions as well as economy of operation. For example, the vertical distance between the water level on the filter and the outlet of the filter which constitutes the head under which it is being operated should be about ten or twelve feet in order to get the maximum output between washings of the filter.

If local conditions make it impossible to carry the filter effluent pipe some distance below the bottom of the filter, the filter would be built deeper than the customary 8 ft. and still give a total operating head within the limits just mentioned. On the other hand, if conditions make it necessary, the depth of the filter could be reduced by cutting down the depth of filter material, lowering the top of the wash troughs and not allowing as much space above the wash troughs for variation of water level. In any event, however, it is very poor practice, except where absolutely necessary, to reduce the inside depth of the filter more than a few inches or at most a foot below the generally accepted minimum depth of 8 ft.

Underdrain System.—The underdrain system of a filter was originally designed to accomplish three purposes, first, collect the filtered water from under the gravel bed; second, distribute the wash water; third, prevent the passage of sand from the filter. Nowadays, most practical filter engineers realize that a properly graded gravel bed can be relied upon even more than the strainer system to accomplish these results.

Although there have been many types of strainer systems developed in recent years, the fact remains that the older form of strainer system constructed of perforated pipe laterals and modified to meet any particular requirements is still more popular than any of the newer types. This, as above stated, is principally due to the fact that improvements in the design of the gravel bed have robbed the strainer system of some of the principal functions. As far as we see it, the merits of one form of underdrain system over another should be determined chiefly by minimum friction loss, during ability, economy in first cost and maintenance, easy access for cleaning or repairing.

Layer No.	Passing a Screen Having Circular Openings of the Following Diameter	Retained on Screen Having Circular Openings of Following Diameter	Depth of Gravel Layers
1 (on bottom)	2½ in.	1½ in.	4 in.
2	1½ in.	1 in.	4 in.
3	1 in.	½ in.	4 in.
4	½ in.	¼ in.	3 in.
5 (on top)	¼ in.	1/12 in.	3 in.
Total depth			18 in.

Thickness of Gravel Bed.—From what has just been said, it follows that the gravel bed placed over the underdrain system is a most important element in the filter. By using a layer of coarse gravel immediately over the strainer system and placing upon this layer successive layers of smaller sized gravel tapering the bed from coarse at the bottom to fine at the top and by making the total depth of gravel between 18 in. and 24 in., it is possible to prevent the loss of sand and at the same time obtain uniform collection of filtered water and a correct distribution of wash water.

Sanitary engineers working independently of each other have gradually developed specifications for gravel bed that are very similar. In one of our largest filter installations of recent date, the specifications call for the following gravel sizes and depth of each layer, and these same specifications with slight modifications are almost generally used nowadays.

The Sand Bed.—The quality of the water to be filtered determines to some extent the size of sand grains and depth of sand bed that would be most effective. The largest sand grains that will obtain satisfactory filtration are apparently the best to use as they offer less resistance to the flow of water during either the filtering or washing process. For all practical purposes, a filter sand having an effective size of between 0.40 and 0.50 mm. with a uniformity coefficient not in excess of 1.7 is suitable, provided, of course, that it has a high specific gravity and contains a minimum amount of perishable substances, such as lime, etc.

The depth of sand bed most commonly used is 30 in., although some designers, realizing that only the first few inches of sand on the surface of the bed do practically all of the filtration, have reduced this depth to in some cases 27 in. and even below.

Assuming that provisions have been made to satisfactorily coagulate and settle the water before applying it to the filter, there seems to be no real foundation for specifications calling for sand much finer than 0.40 mm., as small sand grains increase loss of head through the filter, necessitating more frequent washing without apparently increasing the efficiency of filtration. Naturally the more uniform the sand grains run in size the less likelihood there will be of unequally distributing it during the washing process.

There is still some difference in opinion as to whether rounded sand grains are preferable to sharp grains, but as far as we know, no conclusive evidence has been presented to solve the problem definitely one way or the other. In any event, if sharp grains of sand are used, they will in time become more or less rounded by the washing process.

Wash Water Provisions.—Wash water troughs are designed of sufficient size to discharge the wash water freely without filling up under maximum wash water rate of flow. The top edges of each trough should be absolutely level and the top edges of all troughs in the filter should be in the same horizontal plane with each other. The troughs must be placed at just the proper height above the sand bed. If too high, much of the heavy sediment will fail to pass into the troughs, and after the washing process will settle back on top of the sand. If too low, sand will be carried over into the troughs.

As a general rule, the top edges of the wash troughs should be about 2 ft. higher than the surface of the sand bed, although naturally this distance is controlled by the rate of wash water that is to be used. The troughs must be placed close enough to each other so that the horizontal travel of the water will not be too great. If the troughs are too far apart, much of the dirt which is carried with the water will settle out before it reaches the troughs. If the troughs are too close to each other, there is a likelihood of carrying sand into them. A common practice is to place the troughs parallel to each other and about three and a half feet apart.

Effluent Rate Controller.—In order for a filter to maintain a uniformly high efficiency, it is necessary that the rate of flow through it be kept within the limits of its capacity. It is furthermore imperative that no sudden change in the rate of flow should occur, as this might cause a serious disturbance in the sand bed. To obtain these results, an effluent rate controller is placed in each filter outlet pipe. The merits of one type of controller over another are determined by many considerations, some of which are as follows: Its ability to maintain with a minimum of error any rate for which it has been set, irrespective of the changes that take place in pressure within the filter. Facility for regulation of the controller for any desired rate without undue loss of time or trouble. Its gradual responses to such changes in rate without sudden shocks. Simplicity of design and minimum loss of head required for its operation. Durability, economy of maintenance and repair and accessibility to moving parts.

While the filter is in operation the impurities removed from the water gradually accumulate and build up a resistance to the passage of water through the filter to such an extent that finally the filter will fail to yield its normal output. Most efficient results are obtained if the filter is washed just before the drop in output occurs. Naturally, if the filter is washed before this time, there is a needless waste of washwater. If filter is allowed to operate under decreased capacity, it not only interferes with the requirements for filtered water, but there is also a possibility of compacting the sand bed to an extent that would require excessive washing with consequent disturbance of the filter materials. It is therefore necessary to provide a device known as a loss of head gauge, which indicates to the filter operator the proper time for washing the filter.

Methods of Control.—The operating values of a filter may be controlled manually, hydraulically or electrically. Electrically operated valves fulfill all of the requirements of the hydraulic valves insofar as ease of operation and labor saving are concerned.

If first cost would be entirely disregarded, there would be no reason for using hand operated valves as they entail loss of time and extra effort. Besides, the valve stands used to manipulate them are of necessity so placed as to waste space and detract from the appearance of the plant. When the valves are hydraulically operated, they are controlled by an attractive looking table made out of marble or other material and concentrate the efforts of the filter operator and make it less possible for him to manipulate the incorrect valve. In a large filter plant it is imperative to use hydraulically operated filter valves first because the valves are large and would be unwieldly to manipulate by hand, second, because they save labor and effort. Some of the smaller plants do not absolutely require the use of hydraulically operated valves, and on account of their greater first cost depend upon manual control. As stated above, however, it would be preferable to have valves hydraulically operated even in small filter plants, but limited funds frequently prohibit this.

There are many other useful devices used in connection with a rapid sand filter, such as gauges for indicating or recording the rate of flow of water through the filter, appliances for obtaining samples of water from different sources in the filter plant, wash water rate controller for maintaining a uniform rate of wash water to the filter, etc. These, however, have to do more with the operation of an entire filtration plant and as the scope of this

paper is limited to design data pertaining only to the filter unit itself, we shall not attempt to go beyond this limitation.

In order to be brief, the writer has in some instances made bare statements without attempting to prove them, and has by no means covered all the important points of design of a rapid sand filter, but only what he considereed the elementary features.

Tracing Underground Waters

How Uranine Dye Was Used to Locate Outlet of Creek

By A. W. CROUCH
Resident Engineer, The Tennessee Power Co., McMinnville, Tenn.

IN connection with some recent work at the Great Falls Plant, located near Rock Island, Tennessee, it was necessary to locate the outlet of a small sinking creek lying some eight miles north-east of the plant. After a study of the whole situation and some ineffective tests with potassium permanganate several tests were made using uranine dye. This dye was found very effective in tracing underground water.

General Conditions.—Sinking Creek emerges from the ground at the foot of a low mountain ridge about two miles north of the town of Doyle. It flows on the surface of ground in a south-easterly direction for about ¾ mile and sinks in an irregular row of small holes along the foot of a limestone bluff.

The rock formation in this section of the country consists of Bangor limestone with a dip to the East of 30 ft. or less to the mile. The beds of rock vary in thickness from a few inches to many feet with numerous clay seams and clay pockets scattered throughout the area. Caves, underground streams, sink holes and springs are very common over the entire section. The Calfkiller River, flowing south, is about three miles east of the sink hole in which the dye was placed while the Caney Fork River, flowing west, is about five miles south of the sink hole. There are many springs of various sizes along the banks of both rivers.

A rather definite line of sink holes and caves extends from the point where Sinking Creek disappears to a point on Calfkiller River known as Hensley's Spring. By air course it is 2½ miles away. Taking this fact into consideration together with the fact that the rock dips to the east it seemed probable that the Hensley Spring was the outlet for Sinking Creek although later developments proved that this was not the case.

What Uranine Dye Is.—Uranine dye is a coal tar product, being one of the numerous compounds derived from resorcin. The latter is made by fusing gum resins with caustic potash. Uranine is a reddish brown powder, which when dissolved in water, turns the water green. It is particularly adapted for coloring large volumes of water as it is easy to handle, readily soluble, safe and can be detected when present in very small quantities. From some rough test made in the laboratory it was easily seen when present one part in five million. It can be detected when present one part in ten million. When present in small quantities it is most easily seen by placing some of the water with the dye in it in a test tube and holding it so that the light strikes the side of the tube.

All the tests were made during the month of October, 1927. The stream flow in Sinking Creek at the point where it sinks was 1.4 cu. ft. per second at the time of the tests. No appreciable amount of rain had fallen for several weeks. As stated above it was expected that the outlet would be found along the Calfkiller River and it seemed reasonable to suppose that it would not take over one or two days to get results.

How the Tests Were Made.—One and one-half pounds of dye was dissolved in water in large tubs and dumped into the creek at the sink holes in the first test. At the end of the second day no trace of the dye had been found at any of the springs along either river. Another pound of dye was then poured directly into the sink holes without first dissolving it in water.

On the morning of the fifth day after the first batch had been put in Sinking Creek green water was found at the Johnson Spring, on Calfkiller River, located three and one-half miles south-east of the point where Sinking Creek disappears. The stream flow at this spring was 2.7 cu. ft. per second. By night-fall all trace of the Uranine had passed. Two days later or five days after the second batch of dye had been put in the creek green water was again noticed at the Johnson Spring. As in the first case all the colored water had passed by dark. Judging by the strength of the color in the early morning it is probable that the Uranine was first present at the Johnson Spring some time during the night preceding. This spring is 71 ft. below the level at which Sinking Creek disappears.

A third test was made two weeks after the first two under similar weather and stream flow conditions. In this test a glass jar was placed in the middle of the stream 15 ft. above the sink holes. At the start of the test one ounce of Uranine was dissolved in water and poured directly into the creek. A continuous stream of water containing the dye was then discharged into the stream from the glass jar through a glass siphon at the rate of one ounce per hour dissolved in 2 or 3 gal. of water. Every half hour an extra heavy dose was poured in the creek. After continuing in this way for 4½ hours another ounce of Uranine was poured directly into the creek. A total of eight ounces of Uranine were used in this test. The dye was well mixed with the creek water before it sank to insure a more uniform distribution of the color. It was thought that all the small sink holes might not discharge into the same channel underground.

Colored Water Appears.—On the morning of the fifth day after the dye had been put in Sinking Creek green water appeared at the Johnson Spring on Calfkiller River. The color was the brightest on the afternoon of that day and could be seen up until late in the afternoon of the following day. Colored water was also found in a well at Onward 4½ miles south-south-west of the sink holes. This well is fed by an underground stream, the bed of which is about 6 ft. lower than the place where the Uranine was introduced. On the sixth day the water from Reno spring, five miles South of the sink holes and on the banks of Caney Fork River, was green up until about 11 o'clock. This spring had a discharge of about 1 cu. ft. per second and is 87 ft. lower than the sink holes where the dye was introduced. It has been reported but never verified that green water was also seen at a small spring one mile West of Reno.

Preliminary investigations indicated that the outlet of Sinking Creek would be found along the Calfkiller River. The outlet at Johnson's spring was in line with this reasoning. The outlet at Reno was a surprise. It is evident that a study of the rock formation and general topography of the country will prove helpful in locating the probable direction that an underground stream will take but such a study should not be relied on entirely. Close watch should be maintained at all springs in the neighborhood.

Measurements of the stream flow should be made at both the point where the stream sinks and at possible outlets in order that proper quantities of Uranine can be put in the water. Allowances should be made for the many uncertainties that are sure to be encountered.

Conclusions Regarding Use of Dye.—It appears to be advantageous to put the Uranine in the stream to be traced in small quantities over a long period rather than to dump the whole batch of dye in at one time. The advantage lies not merely in the fact that the color is retained in the water longer but that it gives the observer time to get from one spring to another throughout the territory before the effect of the dye has passed.

Acknowledgment.—The foregoing is taken from a paper presented by the author at the Third Annual Meeting of the Kentucky-Tennessee Section of the American Water Works Association, held at Louisville, Ky.

Automatic Traffic Control Signals for Boston

PLANS and specifications have been completed by John F. Hurley, Traffic Engineer, Traffic Engineering Division of Boston, Mass., for the first unit of automatic traffic signals for the downtown section of the city.

The accompanying plan shows the area to be controlled under present plans. This is known as Unit No. 1. This plan provides for automatic lights on Washington St., from Broadway to Haymarket Sq.; on Tremont St., from Broadway through Scollay Sq., Bowdoin Sq. and Cambridge St. to Temple and Staniford Sts.; on Boylston St., from Arlington St., through Park Sq. to Tremont St.; on Park St.; on Beacon St., from Park St. to Tremont St.; on Summer St., from Arch St. to Washington St.; and provides for the regulation of traffic flow on the connecting streets between Washington St. and Tremont St., from Broadway to Court St.

A comprehensive automatic control system for the entire downtown district, northeast of and including Massachusetts Ave. is the ultimate plan. Unit No. 1 is the first link in this chain of signals and is so designed that future installations may be added and may be operated through the same cables without overloading them.

Central Control.—The traffic flow will be regulated by a central control device located at City Hall. This central timing device will be designed to accommodate all future interconnected installations in the downtown area.

Progressive control signals will be installed, so called, because they are timed to permit a continuous movement of traffic at a predetermined speed. For example, this scheduled timing, it is expected, will make it possible for any driver once in step with the traffic signals on Washington street, to move northerly through Washington St., Adams Sq. and Haymarket Sq. under normal traffic conditions, with no steps at intersections, provided a speed of approximately 15 miles per hour is maintained. Both the speeder and the laggard will be penalized at the next control intersection if, in any block, he exceeds or falls below the set schedule. This detailed timing plan gives each cross street an adequate opportunity to move its vehicular traffic and especially provides for more frequent opportunities for pedestrian crossing. Under the recommended timing the maximum wait of a pedestrian for a clear opportunity to cross Washington St. will be 40 seconds, which is a material reduction of present practice.

15 Mile Speed.—By actual test runs made, the average vehicular speed on Washington St., between Broadway and Haymarket Sq., is less than seven miles per hour. Under the proposed timing method an average speed of 15 miles an hour can be obtained.

While the speed has been fixed at approximately 15 miles an hour in the downtown area, this speed may be varied from the central control station as conditions will require. It is customary to reduce the speed during morning and evening rush hours and during periods of rain, snow or slippery conditions.

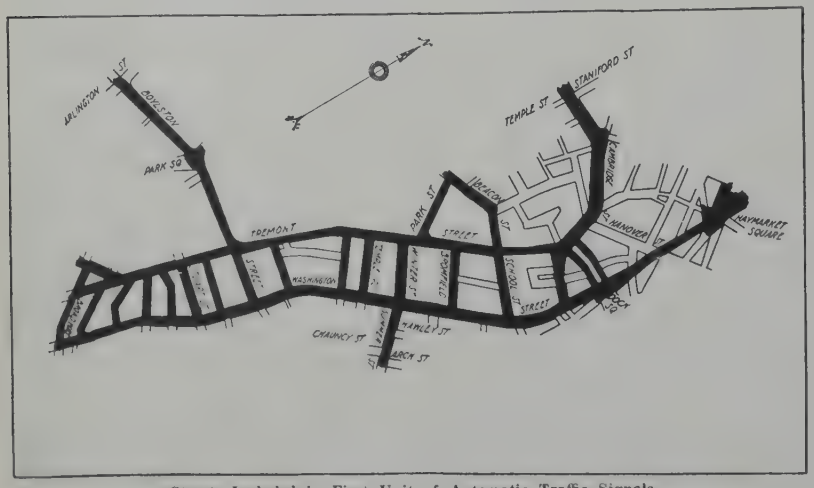
Traffic Light Mounting.—All traffic lights will be mounted on posts on the far right corner where practical. Where a far side mounting cannot give adequate visibility, an alternate or auxiliary signal will be mounted at or near the point where vehicles are required to stop.

The control system is so designed that the lights at any one intersection may be turned off at that intersection, during an emergency, without affecting the operation of the balance of the system. When shut off in this manner the mechanism continues in operation so that when the lights are again turned on they will be in step with the rest of the system. The entire circuit can be shut down at the central control station.

Present plans call for delivery of the equipment in April. It is expected by that time most of the cable construction work will be completed so that installation of the lights may start immediately after delivery. Most of this installation work must be done at night to avoid traffic congestion. Approximately three months will be required for the completion of the installation.

While the installation of Unit No. 1 is in progress, plans will be in progress for Unit No. 2, along Massachusetts Ave.; Unit No. 3, along Summer St., Washington St. North and Cambridge St. extension; Unit No. 4, along Commonwealth Ave. and approximately 25 isolated intersections in the outlying districts.

A traffic engineering division has been established to carry on this work and to conduct scientific engineering studies relating to traffic movement, congestion and accidents throughout the city. Dr. Miller McClintock of the Erskine Bureau for Street Traffic Research has been retained as consultant to work with this new division.



Streets Included in First Unit of Automatic Traffic Signals

New Type of Airport Floodlight

At the International Aeronautical Exposition and Conference at Chicago and Washington the General Electric Company introduced a new type of airport floodlight. The new airport floodlight, designed by C. A. B. Halvorson, designing engineer of the lighting department at Lynn, Mass., contains 14 high-power incandescent lamps, giving a total of approximately three million beam candlepower. The lamps are arranged in a row in front of six cylindrical mirrors that spread the light over the field without permitting it to rise high enough to interfere with the vision of pilots landing directly into the beam of the powerful floodlight. At a distance of a mile from the floodlight there is stated to be sufficient illumination so that a newspaper can be read; and at 2,500 ft., the average maximum airport distance, the illumination is said to be sufficient so that landing pilots can quickly and accurately determine the nature of the landing surface. The plane-parabolic mirrors give the light a spread of 160 degrees horizontally and only three degrees vertically; but, since the reflectors can be adjusted, it is an easy matter to keep all of the light below the line of vision of pilots. Among the advantages claimed for the new design are that a uniform distribution of light is obtained, and a higher intensity of illumination per kilowatt of input is secured.

Importance of Proper Accounting Systems for Municipal Water Works

Important Phases in Accounting That Should Be Considered

By THOMAS S. DURHAM
Division of Accounts, Washington Suburban Sanitary District, Hyattsville, Md.

There is no problem in municipal operations more important than the adoption of a thorough system of accounts through which a full and comprehensive report of the municipality's financial condition may be determined at any time. Everybody knows and will readily acknowledge that it is impossible to guess at the cost of any operation and use this guess as a basis for accurate accounting records. A record that is not true is practically no record at all. Why do we have to keep records? I shall answer that by asking why you keep an account of your personal bankroll? You keep it because it measures your progress and clearly defines your limitations.

In connection with the foregoing I wish to ask three pertinent questions.

1. Do you keep your accounting records so that at any time you can ascertain the true cost of your water system?

2. Have you absolute proof that the municipal organization, for which you are directly responsible, is managed economically?

3. Do your cost accounting records reflect the proper credit to which your administration may be entitled?

I shall not ask you to answer these questions nor shall I go into a detailed description of an accounting system, as the time allotted will not permit, but shall try to illustrate briefly some of the important phases that are necessary to become familiar with, in order to operate and judge results in water works accounting systems.

Need for Uniform Classification.—In the first place a mere recording of transactions, without looking towards an ultimate purpose, cannot give adequate information for financial guidance. In the second place maximum results cannot be obtained unless similar information is kept by a number of allied concerns. If a uniform classification of accounts were adopted by all municipalities in this state, and the combined result studied, each municipality would receive information that could be used to materially reduce nearly all phases of operating cost. We have to know how to use these data after they are compiled. We shall take, therefore, the most important of financial statements, the balance sheet, and see what it is and why we use it.

The balance sheet of a business is like a photograph of a construction project. The photograph well tell you the exact condition of the job at the particular moment it is taken. A succession of balance sheets is a series of photographs showing your financial progress. It shows your assets and liabilities classified in such a way that it is easy to jurge the condition of your business. A glance at the debts that are due or nearly due might reveal that there will not be enough cash in the treasury to pay them. This will be your clue to get busy and immediately provide for more cash before the embarrassing situation actually confronts you. This comparison also indicates the solvency ratio.

Comparative Balance Sheet.—The comparison of each asset or liability, showing the net increase or decrease for the current period, is readily made. This affords information concerning the degree of progress. This is made particularly easy where the comparative balance sheet is used, because the totals at the beginning of the current period are listed alongside of the totals for the current period. In this way the net increase or decrease in each item is shown. The difference between the depreciation reserves and fixed assets will show the present worth of these assets. Deduct from this the fixed indebtedness and you have the present worth of your entire system. By comparing the fixed assets with the fixed liabilities the stability ratio is obtained. In fact, any number of ratios showing both financial and operating results can be made. The possibilities of use to which the balance sheet may be put are too many to discuss exhaustively but remember that the person who does not study his balance sheet is like the person who does not count his money.

Handling Bond Issues.—Each municipality has to depend largely upon its borrowing power to raise any sizeable amount of money. The most general method of doing this is by bond issue. The type of bond issued frequently for water system construction is the sinking fund bond, but there are cases where serial or other types of bonds are used. Regardless of whether the sinking fund or another type of bond is issued there is one point that needs to be stressed particularly. This is the extreme importance of formulating some definite plan for paying the interest on and retiring the bonds at maturity. We will try to see what happens when this is not done. The town of X issued bonds to install water supply and sewerage systems, no definite provision being made to set aside certain sums of money periodically to be applied to the liquidation of these obligations. The assessment may have been high enough to have amply taken care of this need, but the income was used for plant expansion and other expenses seeming more necessary at the time. The time is at hand when the bonds must be redeemed. There is only one step to be taken and that is to re-finance by another bond issue.

It is immediately known that the town of X is in financial difficulties. The market value of its bonds drops and instead of receiving a premium the town has to accept a large discount, which adds another heavy item to the debt. The town might even experience great difficulty in finding a market for its bonds. You can plainly see that it is an unwise step to allow bonds to become due without having provided for their retirement. At best there is confusion and embarrassment for each person that is in any way responsible for such a condition. Refinancing always tends to bring financial soundness into question and affects greatly the possibility of future expansion.

The foregoing is not imaginary as it has actually happened a number of times in this state. The Washington Suburban Sanitary District took over the water system of one town that would have faced re-financing in a comparatively short period but had made absolutely no provision to care for the situation.

Taking Care of Depreciation.—We are all interested in depreciation because it vitally concerns every utility. We have to know something about it to make rates, levy assessments and fix valuations. I dare say that no other subject in public utilities has been more discussed and still is so vague. It is absolutely necessary to provide in some way to take care of depreciation. Otherwise, at the end of the service life of any material asset we would be left with only an empty bag to hold. I am not prepared to say whether cognizance should be taken of actual or theoretical depreciation, but it would seem from observation that the theoretical straight line method will very nearly serve in the ordinary case. Even in this method there are certain factors to be borne in mind, such as inadequacy, obsolescence, growths in water mains, electrolysis

and molecular changes, that will cause a revision of rates.

In the accounting for depreciable assets a plant ledger should be used. The plant ledger is a subsidiary record showing in detail the assets that are carried in one account in the general ledger. In this way all related assets can be kept together with a complete history of each item. This makes possible the knowledge concerning the individual service life of each asset and provides maximum ease in figuring depreciation or the adjustment of rates. Depreciation should be considered in any financial report and the proper reserves shown. The actual taking of a reserve provides a security against the lessening of invested capital. It has to be built up from operating funds as any other cost of the plant would be taken care of. The presence of depreciation reserves indicates conservative and sound managerial policies.

Cost Accounting Not Complicated.—Many people get the impression that cost accounting has some very mysterious qualities, but I assure you that it is not true. It is nothing more than the method of searching out and recording all costs that go to produce a unit of any product. The same principles must be applied to cost accounting as are used in general accounting. The purpose of cost accounting is to render easy comparison of unit costs and make it possible to exercise greater efficiency and economy in extending and operating your system. For example, suppose the expense of installing 6-in. water lines was $2.30 per foot year after year in a certain city. No attempt has been made to find what it costs other agencies to install similar work. Later, there comes to your attention the costs of several cities or companies and, upon comparison, you are astonished to find that the average cost for laying 6-in. water pipe is only $2.13 per foot. You would surely make a decided effort to locate this difference in expenditure. The above test can be applied to each and every operation that is essential in the water system, but to do this there must be uniform cost keeping among municipalities.

In modern commercial concerns the officials find that it is less costly to profit by the mistakes of others than to learn through their own experiences. For this particular purpose they have issued cost accounting statistics through which they obtain cost ratios and percentages that enable them easily to detect and remedy any items of expense that are too high or too low. They find that through comparison with like businesses they may learn their own comparative expense and are thus enabled to set about making changes necessary to increase their profits. The municipal water department or water company can be run on the same general plan.

Value of Uniform Records.—Through uniform cost accounting records we are enabled to tabulate the costs of each size of main laid during any period. These can again be divided according to foremen, which affords information that will allow the elimination of non-producers. This may bear an important relationship to future lower costs, which, in itself, may more than doubly compensate for the expense of obtaining the information.

If you are to be certain that your schedule of charges for water consumption is adequate, you must know the exact expense of producing a unit of salable water. This can be accomplished only by having a definite procedure for your guidance. If you fail to do this, there are items that will be forgotten, items of which you have no immediate record, items that you may leave for proration until some other time. The form you use should tie up definitely with your general accounting records. This will leave nothing for you to forget. You can then say definitely, for instance, that it costs 17¾ ct. per thousand gallons for your gross pumpage and 21 ct. per thousand gallons for water actually paid for by the consumer.

It is necessary to know not only the total cost but the exact cost of each operation that goes to make the completed unit. Following this procedure we discover items of excessive expense and can set about to remedy them.

In municipal utilities the users and taxpayers are the stockholders. They cannot directly share in the profits but a minimum outlay of money by them for a particular utility means a saving, and consequently a profit, to them. It devolves upon you, therefore, as administrative officials, to show the stockholder that his public utility expenses are low as compared with his outlay for other necessities. In this way the municipality as a whole will know that the profits are clearly shown and that you have played your part well.

Acknowledgment.—The foregoing is a paper presented at the Second Annual Conference of the Maryland Water and Sewerage Association.

Cost of Sewage Maintenance at Baltimore, Md.

In our issue of November 1928 there was published on page 255 a table showing data from several cities on sewerage maintenance. In compiling this table the writer obtained his information from various city officials, and noted in his paper that it was possible that some corrections should be made, realizing that some error may creep in.

In the case of Baltimore it is found that this condition exists and that the annual cost of maintenance for the sewers only should be $291,300.00 rather than the amount published. This difference will make the cost per mile $338.70, the cost per million gallons $13.28, and the cost per assessed valuation $0.015 per $100.00.

Millions Voted for Airports

By the popular voting of millions of dollars for airport construction, airports have been established as public utilities.

Nearly $8,500,000 was voted for airports at the November 6 elections. Eleven cities or counties passed bond issue propositions ranging in amount from the $5,000,000 voted by Detroit to the $25,000 approved by the people of Albany, Oregon.

In a few localities the bond issue proposition for airports was defeated but in most such instances the failure was due to circumstances which had nothing to do with the public attitude toward aviation. In Chicago, for example, where every bond issue presented by the present administration in the last two elections have been defeated, the item of $450,000 for development of the airport received the highest vote of all among the defeated projects.

During the last year appropriations or bond issues have been passed which involve more than twenty-one millions of dollars, all of which is to be spent in supplying cities and counties with needed airport facilities.

"The airport," said Captain L. D. Seymour, Assistant General Manager, National Air Transport Co., "has become a public Utility. Communities have come to realize that the benefits of the airport are general. Every aspect of a town's life is affected by the provision of an airport. At Columbus, O., organized labor worked as hard for the passage of the airport bond issue as any group of capitalists. Increased possibilities for all classes of labor were foreseen in the construction and operation of the airport and, more particularly, in the industries which will inevitably follow the establishment of the airport.

"The status of the airport as a public utility has been definitely established. The Supreme Court of Missouri has so ruled, in passing judgment on the validity of airport bonds voted by St. Louis and Kansas City."

In the preliminary designs for the majority of the proposed airports many improvements are included which would have seemed visionary to aviators of pre-war days. Administration buildings are proposed which equal modern railway terminal buildings in size and usefulness. Lighting equipment, air weather bureaus, permanent, fire-safe hangars and paved runways are but a few of the features which have become commonplace in the design of airports; none of these was to be found on any American port ten years ago.

Outer Park System for St. Louis Recommended.—An outer park system which would give St. Louis, Mo., recreation spots in scenic parts of St. Louis County is urged by Fred W. Pape, Park Commissioner, in his annual report to Director of Public Welfare Salisbury.

DISTRIBUTOR NEWS

The Distributor's Department in the Gillette Construction Group

Happy New Year

Santa Claus left us a few distributor stories, so that means a Happy New Year for us. We hope your Christmas stockings were so full of orders that your warehouses will be left quite empty until fresh supplies arrive from the manufacturers, which will mean a Happy New Year for you.

Ninteen twenty-eight is now ancient history and we all have a new Carry On spirit for 1929. We are looking forward with pleasure to a better acquaintance with the distributors in the field, and an opportunity to present their stories to our readers.

Take advantage of this department which is at your service. If you remodel or build a warehouse, open a new office, elect officers, appoint new representatives, or go on a business trip, tell Distributor News about it. We will pass the stories of your progress on to our readers. It is a source of inspiration to the field to learn of the activities throughout the country and to know of so many men all engaged in the same line of endeavor.

Pictures add to the interest of a story, so send us your cuts or photographs of facilities or officials of your company. We are glad to hear from you and will use your contributions as far as space permits. Write us often. Address all communications to The Editor, Distributor News, Gillette Publishing Company, 221 East 20th Street, Chicago.

Localized Gatherings

One Way to Help Distributors

By LOUIS McLOUTH

Advertising Manager, Sauerman Bros., Inc., Chicago

EVERY manufacturer of industrial equipment holds an annual sales convention, which gives salesmen and distributors a chance to visit the factory and hear an outline of plans for the coming year. Sauerman Bros., Inc., of Chicago, manufacturers of slackline cableway excavators, power drag scrapers and coal-storage equipment, hold an annual sales meeting, but this convention is taken to the distributors. In other words, the Sauerman plan embraces a series of small, localized gatherings, rather than one big central get-together.

It would be easier and simpler for Sauerman Bros. to follow the line of least resistance, have their distributors and the latter's salesmen come to headquarters once a year, and call it time and money well spent. Analysis of the situation, however, convinced the company's officers that the greatest possible good could be accomplished by the sectional gatherings, which would be devoted, not to a discussion of national conditions, but how to sell the company's three main lines in the specific territory covered by that distributor and his men.

Thus every fall a flying wedge starts out from the Sauerman plant in Chicago, headed for the home territory of distributors in almost every part of the country. This flying wedge is made up of D. D. Guilfoil, sales manager; the advertising manager; W. R. Elden and H. A. Roe, engineers, and the district sales manager for the section being invaded.

On November 14 and 15 this quartette held a meeting with the distributor for the Indianapolis territory. Earlier in the month, November 8 and 9, it went over the situation with the distributor at Dayton, Ohio. Other meetings have been or will be held in St. Paul, Milwaukee, Detroit, Baltimore, and New York.

The local convention plan was adopted after it had been determined from contact with distributors and general observation that conditions in almost every part of the country differ from those in any other section. One territory may be prosperous and another may be experiencing a depression; one section may be chiefly agricultural and another may be mining; demand in one territory may be chiefly for excavators, while in another it may be largely for coal-storage equipment.

This being true, Sales Manager Guilfoil decided that the logical way to approach the sales problem was to break down the country into sections, as covered by distributors, and then to join the distributor, at least once a year, in a face-to-face discussion of what could be done to increase sales in that particular territory. The distributor's salesmen, of course, come in for the local meetings and present their own individual problems.

Mr. Louis McLouth, Advertising Manager, Sauerman Bros., Inc.

This means a lot of work for the men elected to attend these district meetings from the main office. The sales manager, even if he were so inclined, could not dismiss the discussion of selling scrapers to contractors in Ohio with a few glittering generalities. The advertising manager cannot quote a few figures showing how his company covers prospects with advertising all over the country.

On the contrary, Mr. Guilfoil goes before each meeting with a sheaf of sales statistics compiled for that particular group of salesmen. I cannot content myself with totaling the country-wide circulation of advertising mediums employed, but must break that circulation down by states, so that I can and do tell distributors and their salesmen just how many sales messages are being fired every year in their own territory.

The time spent in making these territorial breakdowns is justified in more ways than one. I learn a lot when I get this slant on the advertising situation. Likewise, the distributors' salesmen are more forcibly impressed with the figures relating to their own territory than they would be with the national coverage, because the latter has only a general meaning to them. But when you start talking about advertising in their own territory, and to the men they are trying to sell, you get both an intensely interested and a highly enthusiastic audience.

The same is true of the addresses of the sales manager, the district sales manager and of the engineers. They localize their data as far as possible, so that their remarks are made with a consideration of local conditions and to men who have to meet those conditions.

It is gratifying to see the impression made on distributors and their salesmen by the advertising circulation figures. They had no idea that the number of magazines, consolidated catalogs and directories spreading our advertising message throughout their territory was so large. After looking at these figures, their conclusions seem to run something like this: "Well, we don't see much about excavators and drag lines in the newspapers, but the figures show that it is really a big business—one we can be proud of."

They leave the convention with renewed enthusiasm, as well as additional facts which they can use in their daily work.

Most of the Sauerman district meetings are held in November and December, when the demand upon the sales department is at the lowest pitch of the year. The meetings are thus held with a minimum of loss of business.

The meetings are of the blackboard and brass tack variety. They are far more intimate than would be possible under any other conditions, and because they are intimate and of a man-to-man nature, salesmen who might ordinarily feel some constraint make bold to come out and state any problem which is bothering them. The sales manager gives the answer in the same frank way, and all of those present gain from the discussion.

The meetings are held in the quarters of the distributors in some cases and in a local hotel in others. The average meeting lasts two days. While the days are devoted to business, the entertainment feature is not omitted, one of the local hotels providing facilities for a dinner and any other program which may be desired.

The Sauerman headquarters staff is constantly on the road during these two months, and the convention period is quite a strain because of this long absence and the continuous traveling. Only the conviction that more in the way of actual results is accomplished in this way than in any other would justify this arduous effort. But Sauerman Bros. have given the plan a thorough trial, and as far as they are concerned the old mass convention is a thing of the past.

Distributor Notes

The Sidney Steel Scraper Company of Sidney, Ohio, of which Mr. John Perry is president, announces the organization of the International Automotive Equipment, Inc., a new corporation for the purpose of marketing the new patented Perry Automatic Dump Truck Body. The Sidney Steel Scraper Company has contracted to manufacture bodies on order of the Sales Corporation. The new body will be shown at the Road Show with the exhibits of the Sidney Steel Scraper Co. and the Perry Company.

Arthur E. Little

Mr. Arthur E. Little, well known in the industrial advertising field passed away after a brief illness. Mr. Little was formerly advertising manager of the Thew Shovel Company at Lorain, Ohio, and was one of the speakers at the 1928 convention of the National Industrial Advertisers' Association at St. Louis.

He was a technical expert and capitalized his knowledge in the industrial advertising field. Previous to going into the advertising work he served as a draftsman with the Cleveland Frog & Crossing Company, and chief engineer of the Jahant Heating Company. He then became connected with the advertising department of the Firestone Rubber Company, and after the war served with the Paul Teas, Inc., Cleveland and the Thew Shovel Company, Lorain.

Charles Seitz

In the recent and tragic death of Mr. Charles Seitz, the United States Cast Iron Pipe & Foundry Co., of Burlington, N. J., has lost a respected and able member of their organization. Mr. Seitz's death was the result of an automobile accident which occurred on November 30th. At the time of his death he was the Resident Manager of the Addyston Shop.

Mr. W. E. Lewis, formerly Resident Manager of the Anniston Shop of this organization has been transferred to Addyston, to fill the position left vacant by Mr. Seitz.

Branch Manager Transferred from Milwaukee to New York

Mr. H. N. Felton, formerly branch manager of the Milwaukee office of the Wagner Electric Corporation, St. Louis, has moved east to take charge of the New York office. Mr. Felton is a graduate of the University of Illinois, and served two years in the Army. He entered the Chicago district of the Wagner Company as a salesman and in 1927 was made branch manager of the Milwaukee Branch, where he continued until he was transferred to New York.

In Southern Territories

THE Dealers Equipment and Implement Co., Memphis, Tenn., distributors for the McCormick-Deering Industrial tractor and the Trackson Company's lines of equipment, have found the Trackson McCormick-Deering unit an ideal crawler tractor for road building and maintenance, according to Mr. Dunbar Abston, Vice President of the Company.

Highway work is this company's most important sales field, and the Model DH Trackson unit has proved an economical, efficient solution to the equipment problem. This year, especially, the Memphis territory is occupied with extensive road work and levee construction programs and State, County, and City officials have shown tremendous interest in the Trackson McCormick-Deering combination.

The accompanying illustration shows officials of the Dealers Equipment and Implement Co., and other members of the organization grouped around the Trackson in front of their attractive show rooms. Mr. Abston is shown at the wheel of the tractor; Robert Rust, Manager, is third from the left, with his arms folded, and Irvin Kunert, Trackson Company representative, is first to the right of the machine.

Mr. Dunbar Abston, Vice-Pres. of Dealers Equipment & Implement Co. at Wheel of Tractor; Mr. Robert Rust, Manager, Third from Right, and Mr. Irvin Kunert, Trackson Co. Representative, Immediately at Left of Tractor

The Offices of MUNICIPAL NEWS AND WATER WORKS, 221 E. 20th Street, Chicago, are headquarters for information on equipment and supplies. If you want catalogs, prices or names of manufacturers, we will gladly supply same free.

Convention of Corrugated Culvert Makers Held at Massillon, Ohio

Late in the fall a meeting of the Toncan Culvert Manufacturers' Association was held at Massillon, Ohio, to formulate plans for selling and advertising activities for 1929. The members assembled in the executive offices of the Central Alloy Steel Corporation.

The utmost optimism was expressed regarding the business outlook for 1929, and practically every section of the United States and Canada was represented at the conference. A considerable expansion of the Association's trade activities was decided upon to be started at once.

Several new members, acknowledged leaders in their respective territories, joined the Association during 1928, thereby adding strength to the organization, and plans have been made for enlarging the membership still further in 1929. Officers for the ensuing year were elected, and a meeting scheduled for August.

Change of Address

The Cutler-Hammer Company of Milwaukee, Wisconsin, announces that after December 1st the address of their Atlanta, Georgia, office will be 150 Peters Street. This office will furnish sales and engineering service on Motor Control apparatus and Wiring Devices, and will also have warehouse facilities for carrying in stock many types of standard devices. This will insure to customers in that territory direct and prompt shipment. Because of the increasing electrical power application to industry in this section of the country the Cutler-Hammer Company has provided this service to anticipate the needs of its customers. Mr. A. C. Gibson is manager in charge of the Atlanta office.

The Power Plant Supply Company, sales engineers and contractors, who have been in business in Detroit since 1911 announce their removal from the Penobscot Building to the new Fisher Building. They will be established in their new quarters after the first of the year. Mr. J. E. Walsh is general manager for this firm.

After January 1st, the address of the Eastern Paving Brick Manufacturers Association, will be 1535 Real Estate Trust Building, Philadelphia, Pa. Mr. William C. Perkins is the Chief Engineer of this organization.

Distributor Notes

The Ross Power Equipment Company, dealers in new and used equipment issue a very complete catalog of their stock. It is well classified and each piece numbered, making it very easy to inquire about any particular piece of machinery. Their announcement states that they have a background of thirty years experience in the power plant and general machinery business. If interested, write to them for a copy of this catalog. They are located at 9-11-15 South Meridian Street, Indianapolis, Ind.

New England Implement Co. Adds McCormick-Deering Line

The New England Implement Company with large establishments at both Boston and Worcester, Mass., is one of the oldest Trackson distributors in the country. They have sold hundreds of Trackson units in New England for road work and snow removal purposes which are their biggest sales fields, and also for general construction work.

Their tractor and equipment business is one of the largest in the East and they recently took over the distribution of McCormick-Deering tractors and the Trackson Company's lines of Full Crawlers and other equipment adapted to use with the International power plant.

Eastern Distributors Add Line of Tractors

Because of the increasing importance of the tractor as a power plant for highway, general construction and industrial purposes, the Tractor & Equipment Company of Newark, N. J., for many years dealers in automobile bodies have added tractors to their equipment line. This company was recently appointed distributors for the Trackson Company of Milwaukee, Wis., to handle Industrial McCormick-Deering tractors and also the Trackson full-crawlers, loaders, shovels and other equipment for the International tractor.

Messrs. Lyman and Holloway of the Tractor & Equipment Co., enthusiastically report a keen display of interest in the outfits making up the Trackson-McCormick-Deering combination. A variety of fields for tractor and equipment sales is offered in the metropolitan industrial section which comprises their territory.

We present a picture of a Model DH Trackson McCormick-Deering unit with Mr. Lawrence Coons at the wheel making a test before equipment is delivered.

Warehouse and Showrooms of Tractor & Equipment Co., Distributors at Newark, N. J. Mr. Lawrence Coons, Tractor Salesman at Wheel of Model DH Unit

New Lines Wanted

Editor's Note—Distributor News receives from time to time letters from distributors wishing to be put in touch with manufacturers of certain lines of equipment which they would like to represent. Items of this kind will be published and names and addresses furnished interested persons upon request.

A man of many years' experience in the machinery business in the south would like to make a business connection for the sale of road machinery equipment.

Machinery company in the east is interested in representing established lines of road machinery, with the exception of graders.

New York company interested in representing manufacturers not already established in eastern market, or considering a change in sales arrangements.

Manufacturers' representatives located in New York would like to add line of heavy contractors' equipment of established reputation, other than the lines now handled by them. They would like exclusive sales rights for such equipment.

A Michigan distributor of many years experience, representing at this time many prominent manufacturers of pumping machinery, offers the services of an established representative to manufacturer needing increased distribution facilities in this region.

A contractor's superintendent located in Florida would like to represent some road equipment manufacturers in this territory.

A manufacturer of paving expansion joints is looking for distributors for Northern California territory.

New Appointments

The Continental Motors Corporation, through the manager of its Industrial Division, Mr. L. J. Kanitz, announces the appointment of Mr. Sid Harris as Industrial Sales Engineer in the East, a field in which Mr. Harris has a wide knowledge.

Independent Pneumatic Tool Company to Enlarge Plant

The Independent Pneumatic Tool Company, 600 West Jackson Boulevard, Chicago, manufacturers of Thor Pneumatic, Electric and Contractors Tools, will build an addition to their factory located in Aurora, Illinois.

The new structure will consist of a modern, fire-proof, concrete construction building and will add 36,000 square feet to their present capacity.

Caterpillar Acquires Russell Grader

On December 13th the Caterpillar Tractor Company announced by telegram that negotiations, which had been pending, had been concluded with the Russell Grader Manufacturing Company of Minneapolis, whereby it had acquired the business and facilities of the latter company. The plant formerly occupied by the Russell Grader Company at Minneapolis will be used by the Road Machinery Division of the Caterpillar Company where they will continue to manufacture the Russell line of road building machines. Hereafter all Caterpillar tractor dealers in this country and abroad will have charge of the sale of Caterpillar tractors, Russell road machinery and Holt combined harvesters. The latter are produced in the harvester division of the Caterpillar Company located at Stockton, California.

The Caterpillar Company, whose headquarters are in San Leandro, California, has announced its intention to build an eastern combined harvester factory at Peoria, Illinois, where its principal tractor plant is now located.

Timken Roller Bearing Co. Establishes Permanent Offices in Far West

The Pacific Coast territory of the Timken Roller Bearing Company has been reorganized, with the result that a permanent office has been established in Los Angeles, California, and one in Seattle, Washington. Mr. Roy Cross, located at 1361 South Figueroa Street, will have charge of the Los Angeles office, and Mr. Marshall Cooledge with address at 321 South Pine Street will direct the Seattle office. Mr. G. C. McMullen will continue to serve from the Company's San Francisco office as district manager.

Construction Machinery Co. Plan Road Show Dinner for Representatives

Mr. R. C. Weller, sales manager of the Construction Machinery Company, Waterloo, Iowa, announces that their annual dinner for representatives will be held at Cleveland at the time of the Road Show. The dinner will take place at the Cleveland Hotel, Monday evening, January 14th. Discussion will center around the many interesting features of the combined Construction Machinery and Marsh-Capron program for 1929, according to Mr. Weller's announcement. Indications point to many improvements to be offered in the new models which are to be shown under the Wonder or Marsh-Capron banner at the Show.

The Construction Machinery line is now one of the most complete in the field with Wonder Tilting Mixers; Marsh-Capron Drum Type Mixers; Mechanical Hoeman Plaster Mixer; Power Sawyer; Construction Machinery Company Hoists and Blackhawk Snow Plows.

New Sales Manager Appointed by Penn. Dixie Cement Co.

The appointment of Mr. Walter S. Wing as General Sales Manager for the Pennsylvania-Dixie Cement Corporation has just been announced. Mr. Wing will be in general charge of the marketing

Mr. Walter S. Wing, General Sales Manager for Pennsylvania-Dixie Cement Corp.

of the corporation's products and will be located at 131 East 46th Street, New York City.

Mr. Wing entered the steel business in Pittsburgh, during the summer of 1907, following his graduation from Cornell University with the degree of Mechanical Engineer. About a year later he was transferred to a subsidiary company, the Universal Portland Cement Company, where he remained until very recently. For the past 13 years his office has been in Pittsburgh, where he served the Universal Company as Eastern Sales Manager.

Public and civic affairs have always interested Mr. Wing and he has taken part as an active member of the United States Chamber of Commerce, Pennsylvania State Chamber of Commerce, Ohio State Chamber of Commerce, Pittsburgh Chamber of Commerce and the Civic Club of Allegheny County. He is also a member of the American Society for Testing Materials, Cornell Society of Engineers, and in Pittsburgh is a member of the Duquesne Club, University Club, Longue Vue Club, Railway Club of Pittsburgh, Automobile Club of Pittsburgh, Pittsburgh Builders Exchange and others.

Browning-Ferris Co. to Handle Tracksons

The Trackson Company, Milwaukee, Wis., manufacturers of Trackson Full-Crawlers, Loaders, Shovels, Cranes, etc., announce that they have arranged with the Browning-Ferris Machinery Co., 205 Exposition Ave., Dallas, Texas, for the distribution of Trackson equipment for McCormick-Deering Tractors.

These distributors will have the entire state of Texas for their territory. They also have branches in Houston, Fort Worth, and Amarillo. They are authorized distributors for McCormick-Deering Industrial tractors, and are in a position to give quick service on the International and Trackson lines.

Wemlinger, Inc., Opens Chicago Office

Word has just been received that Wemlinger, Inc., 149 Broadway, New York City, has opened an office in Chicago at 228 North La Salle Street. This office will be under the direction of Mr. Alexander Mayer who is thoroughly equipped to help the contractors in all matters concerning steel sheet-piling and to render many services to the customers of Wemlinger, Inc. Practical suggestions concerning the product of this company is mailed out in unique folder style each month to interested users of piling. This service is called "Piling Facts" and a line to either the Chicago or New York office, we are sure, will place your name on the mailing list to receive this information.

New Appointments

The Harnischfeger Corporation of Milwaukee, Wis., has enlisted the services of the Ed. P. Phillips Machinery Co., of Richmond, Va., as new district agents for the Virginia territory.

The Phillips Machinery Co., has satisfactorily supplied the needs of a large number of Virginia contractors, over a period of many years. They will handle the complete line of P & H Excavating equipment, including shovels, draglines, clamshells, trench-hoes, skimmer scoops, trenchers and backfillers.

Announcement has been received that McCarthy-Jones & Allen Co., Inc., 111 First Avenue, South, Nashville, Tennessee, has been appointed distributor of all the products of the Botfield Refractories Co., Philadelphia, Pa., manufacturers of Adamant Fire Brick Cement; Adamant-Adachrome Super-Refractory Mixtures and the Adamant Gun.

Murray - Wheeler Company, 329-31 Ellicott Square, Buffalo, New York has been appointed distributor for the Eastern territory for the Erie Machine Shops, Erie, Pennsylvania, manufacturers of Erie steam and gasoline rollers.

By writing the manufacturers named and mentioning this magazine, copies of the following catalogs will be sent to you without obligation

TRADE PUBLICATIONS

Hose Coupling Vib-Restor.—This is the trade name given to the latest addition to the pump industry by the Chicago Pump Company, 2336 Wolfram Street, Chicago. This is a vibration deterrent for horizontal centrifugal pumps presented by the engineering department of this company. It is a scientifically designed rubber hose coupling, special rubber fabric and special couplings being employed in the manufacture. This coupling is recommended by this company where a quiet pump installation is desired. If interested write to Mr. Clem Peterson, at the above address for folder on Vib-Restor. If you will mention this magazine it will be appreciated.

Water Softeners.—The International Filter Company, 333 West 25th Place, Chicago, present in an illustrated bulletin Crystalite, a water softening product. This is an attractive 16 page booklet, well printed on heavy enamel paper. It discusses the chemistry of zeolite water softening; the early history and development of zeolites; Crystalite as a super rapid zeolite; the advantages of upflow softening illustrated with curves. Crystalite Water Softeners installed by the International Filter Company are illustrated, and special industrial uses for Crystalite are listed. If writing for this bulletin, kindly mention our magazine.

Distribution Transformers.—Bulletin 160, recently issued by the Wagner Electric Corporation of St. Louis, Missouri, is a 52-page catalog describing Wagner distribution transformers in a single-phase and three-phase, pole type and subway-type, in ratings up to and including 500 Kv-a. Detailed description of design and construction of these distribution transformers fills the first half of the catalog, while the remainder is given over to ratings, shipping weights, prices, etc. Mr. C. B. Dietrich, identified with the St. Louis office of this company at 4600 Plymouth Avenue, will be pleased to send you a copy of this book on request. If you will mention this magazine it will be appreciated.

Chlorination.—Wallace & Tiernan, Newark, New Jersey, manufacturers of chlorine control apparatus will be pleased to send you full particulars in regard to the sterilization of water by their method, and to furnish you with record of cities where their apparatus is being used. If writing for information, we would like to have you mention our magazine.

Dual Control Trencher.—Bulletin 20-X gives detailed information regarding the P & H Trencher manufactured by the Harnischfeger Corporation, 3902 National Avenue, Milwaukee, Wis. One of the important features of this equipment is the fact that the operator can work from either side. This company has branches in all the principal cities. Write to Mr. H. S. Strouse for copy of this bulletin, mentioning this publication.

Dragline.—Write to Koehring Company at Milwaukee, Wis., or to any of their branches in the principal cities, for Dragline Bulletin DL9. The ease of control and speed in functioning are important features of this heavy duty Koehring equipment. Mr. O. C. Dahlman will furnish bulletin on request. If writing mention our magazine.

Centrifugal Pumps.—Write to De-Laval Steam Turbine Company, Trenton, N. J., for Catalog B-64, which gives detailed information concerning the reliability and economy of these pumps, which are widely used by American municipalities for automatic pumping stations. In writing to Mr. H. B. Watson of this company for the bulletin, kindly mention our publication.

Francois Cementation Process.—The Dravo Contracting Co. have acquired the sole American rights to the Francois patents, and have a highly skilled staff who will be pleased to help you with your problems. This method of grouting covers chemical processes for a hundred and one different cases, the engineers of the Dravo Company are ready to help you solve your problems. Write to their company at Pittsburgh, Pa., mentioning our magazine.

Sewer Cleaning Machine.—W. H. Stewart, whose factory is at Walkerville, Ontario, has branches in St. Louis, Mo., Jacksonville, Fla., and Boston, Mass., so that his patrons on this side of the border may be served without paying duty. Literature describing his sewer and conduit rods will be furnished on request. Rods will be shipped on trial. If writing to Mr. Stewart for information concerning his equipment kindly mention our publication.

Manhole and Catch Basin Covers.—Write to Wm. E. Dee Company, 30 North La Salle, Chicago, Ill., for particulars concerning the different types of manhole and catch basin covers. Prices will be included on request. If writing, kindly use the name of our magazine. This company also manufactures sewer pipe, drain tile, culvert pipe, well tubing, flue lining, wall coping and fire brick.

Cast Iron Pipe.—The U. S. Cast Iron Pipe and Foundry Company of Burlington, N. J., have branches in all the principal cities and will be pleased to send you full information if you will state your requirements. They manufacture pipes for all purposes. If writing for information, will you mention our publication.

Hydrants, Valves, etc.—Full particulars for supplies needed by water works and fire departments will be sent upon request by the Bourbon Copper & Brass Works Co., 618 E. Front St., Cincinnati, Ohio, manufacturers of fire hydrants, gate valves, and extension valve boxes. Write for their catalog, giving the name of our magazine.

Trencher.—Details and specifications of the new Parsons Model-31, the big full-crawler trencher, manufactured by the Parsons Company, Newton, Iowa, may be secured upon request. Before offering this machine to the market it was given a thorough test by its sponsors and they would like to tell you all about it. Like its predecessor, the Parsons 21, the 31 is built to dig at either side or in the center and digs with boom offset so that it can handle close-quarters jobs where some machines might fail.

Valves.—Golden-Anderson Valve Specialty Company located in the Fulton Building, Pittsburgh, have issued a descriptive and data catalog on their automatic valves for steam and water service. Full details are given on each page as to construction, operation variations together with cross-section drawings. Data required for ordering is made very clear. If you desire a copy of this catalog write to Mr. J. A. Voland of the Golden-Anderson Company mentioning the name of our magazine.

Meter Testers.—A catalog giving complete information on the Mueller Meter Tester will be sent upon request if you will write to Mr. C. N. Wagenseller of Decatur, Illinois, mentioning this publication, or they may be secured at any of the branch offices of this company. The Mueller Meter Testers are simple of operation and of a lasting quality of construction. Statistics show that meters under-register oftener than they over-register and an accurate meter tester insures honestly earned revenues. Meters should be tested befor installation and at regular periods

thereafter. The Mueller catalog will give you complete information on this subject.

Zeolite.—"Softening Municipal Water Supplies by the Use of Zeolite" is the title of a bulletin issued by the Zeolite Chemical Company, 140 Cedar Street, New York City. This booklet describes Green Sand, a natural base exchange Zeolite Mineral, used for the purpose stated. Write to Mr. R. E. Wagner of the Zeolite Company for a copy of this bulletin. If writing, we would appreciate it if you would mention this magazine.

Meters.—The Union Water Meter Company of Worcester, Mass., with offices in New York City and Philadelphia, will be pleased to send you literature concerning their King Frost Protected Meter, built to overcome every known weakness in frost meter design. If interested in meters of this type write to Mr. E. K. Otis for full particulars. We would appreciate it if you would mention this publication.

Hydrants and Valves.—The Mathews Fire Hydrants, built for easy installation and so that an extension section may be used to adapt them to new grades, are described in literature of the R. D. Wood & Co., Philadelphia. If you will write to Mr. C. Becker of this company he will gladly send you full information about their sand-cast and "sand-spun" centrifugal cast iron pipe fittings, valves, boxes and hydrants. Please use the name of our magazine if writing.

Automatic Air-Lift.—The Sullivan Machinery Company, 130 South Michigan Avenue, Chicago, Ill., has a handbook on their atuomatic air lift, and special automatic control information of particular interest to water works superintendents. A letter to the Sullivan Machinery Co., attention of Mr. S. B. King, will bring you this information. Ask for Catalogs 6171-I and 6156-J. If you will mention the name of our magazine we will appreciate it.

Filtration Plants.—Officials considering filtration plants will find much interesting information in the literature of the Norwood Engineering Company, Florence, Mass. If writing mention our paper.

Cast Iron Pipe.—James B. Clow & Sons, 201-299 North Talman Avenue, Chicago, with foundries at Coshocton, Ohio, Newcomerstown, Ohio, and Birmingham, Alabama, carry large stock of pipe at points where large supplies can be obtained on short notice. Wire or write them concerning your requirements, they will be glad to care for your needs without delay. Mention our magazine when writing this company.

Lubricant.—The Dot Lubricant Equipment Company, Division of the Carr Fastener Company, Cambridge, Mass., has issued a unique little folder called "Little Journeys in Dot Lubrication," illustrating and describing the various steps in the use of this lubricant. The trip described is that of taking the grease from the storage tank to the bearings quickly, comfortably for the user, absolutely free from dust and dirt.

Centrifugal Pumps.—In order to be of assistance to users in choosing the right pump for their needs, Bulletin 1632-I has been issued by the Allis-Chalmers, Milwaukee, Wis. Types for steam turbine drive, motor drive or gasoline engine drive are described to best fit the purposes of installation. Write to Mr. H. G. Hoffman for copy of this bulletin, mentioning Municipal News and Water Works.

Sanitary Specialities.—Manufactured by the Servicised Products Corporation include Bituminous rope, sewer compound and sewer belts (both acid and root proof), and asphalt liner slabs, proof against sewer liquors. Illustrated literature giving complete descriptions and details concerning these products for obtaining permanently tight and lasting sewers will be sent upon request by the Servicised Products Corporation, 6051 West 65th Street, Chicago, Ill. If you will mention our publication when writing to Mr. A. C. Fischer of the Servicised Company for this information it would be greatly appreciated.

Moir-Buchanan Centrifugal Process.—This process is to obtain high density, low absorption and long life of concrete pipe. Rights to use this process may be secured through the Asphalto-Concrete Corporation, 1440 Broadway, New York City. If interested in learning about this process and how strength and durability are secured by this method write to Mr. Geo. H. Schroder of the Asphalto-Concrete Corporation, using the name of our magazine and ask for full particulars.

Chlorinator.—Bulletin W-21 issued by the Paradon Manufacturing Company of Arlington, N. J., describes in detail the Paradon Chlorinators for city and private water and sewage systems, industrial plants and swimming pools. If writing for this bulletin address Mr. R. V. Donnelly, care of the manufacturer. We would appreciate it if you would mention our publication.

Cast Iron Pipe.—The Central Foundry Company, manufacturers of cast iron pipe with offices located in the principal cities, will be pleased to have you call at the nearest office or write to the New York office, 420 Lexington Avenue, for complete information in regard to their product, an iron to iron joined pipe, allowing for expansion and contraction, vibration and uneven ground settlement. Used for water supply, fire protection and other service.

Valves.—The Darling Valve & Mfg. Company with offices in New York, Chicago, Houston and Oklahoma City and headquarters in Williamsport, Pa., will be pleased to send you full information in regard to the design and performance of their valves which are built to minimize friction and wear. If writing for literature to Mr. A. G. Smith at the Williamsport office of the company, kindly use the name of our magazine.

Pipe Cutting Tool.—A folder from the Tucker Company, Inc., 75 Murray Street, New York City, illustrates and describes the Anderson pipe cutter for cast iron pipe. This tool can be used in any ordinary trench without extra excavating, and will make a clean cut in gas or water main in the trench. All parts are of steel or malleable iron. Prices for the cutter in different sizes are given, as well as a price-list of all parts. Further information will be furnished upon request. If writing kindly mention this magazine.

Rayflectors.—The trade name of patented reflecting devices designed for utilizing light from automobile headlights, or other outside sources, to make signs and signals visible at night. The Rayflectors are manufactured by the Ray-Signs Corporation, of New Haven, Connecticut, and are described and well illustrated in a very attractive, well bound, 12-page booklet. These devices come in three sizes and in white, red, green and amber. This black and gold booklet will be sent upon request by the manufacturer, and we would appreciate it if you would mention our publication when writing.

Road Maintenance.—Several attractive pieces of literature have been received recently from Edw. J. Jockoboice, Grand Rapids, Michigan. A 12-page enamel-paper booklet describes in detail and illustrates the Monarch Road Planer and Maintainer. The sharp and carefully lettered and numbered illustrations both in this booklet and in broadsides issued by this company make it easy to comprehend the outstanding features of this machinery. The blade on the "Perfection Reversible Monarch" Road Planer is set with swinging arms attached to each side of the truck which allows the blade to be swung to reserve angle, thus whether cutting to or from the center of the road the truck is always with traffic.

Seal Tight Expansion Joints.—The necessity for expansion joints, types that have been used, types of premoulded joints, etc., are discussed in a little booklet called Seal Tight issued by W. R. Meadows, Inc., Elgin, Illinois. Allowances must be made for the expansion and contraction of concrete as affected by weather conditions, and this booklet gives results as accomplished with Seal Tight in controlling this problem. Write to Mr. W. R. Meadows at Elgin for complete information regarding these expansion joints, mentioning the name of our magazine.

Portable Compressors.—Ingersoll-Rand Company, 11 Broadway, New York City, will be glad to send you catalog describing their gasoline engine or electric driven portable compressors, in six sizes. If writing for this information, will you please mention our magazine.

Lubrication.—The story of the Alemite Manufacturing Corporation system of lubrication issued in magazine style. This pamplet, Lubrication Maintenance, is published in the interest of better industrial lubrication and lower production costs, and will be mailed free to any one interested. If writing for this booklet, will you kindly mention our publication? The address of the Alemite Manufacturing Company is 2646 North Crawford Avenue, Chicago.

Four Wheel Drive Trucks.—Several pieces of literature have just been received from the Coleman Motors Corporation, of Littleton, Colo., Washington, D. C., and Chicago. The trucks described and illustrated are Model C-25 (2 tons), Model D-40 (3 tons), and Model X-100 (5 tons). Specifications are given and the trucks are shown performing seemingly impossible feats. The front axle of the Coleman truck is placed under the frame at a point that will give an equal distribution of weight upon both axles when the truck is loaded to capacity. This factor adds to the tractive ability and to tire life. Full information regarding any or all models will be sent upon request addressed to any office of the manufacturer. If writing we will appreciate it if you will mention this publication.

Steel Sheet Piling.—Lackawana Steel Sheet Piling, particularly suitable for the long sea wall. For information regarding this product write to the Bethlehem Steel Company, Bethlehem, Pa. Mr. S. H. Yorks is sales-manager. If writing Mr. Yorks, give the name of our magazine.

Hydraulic Dredge Capacity Indicator.—The Ellicott Machine Corporation, 1111 Bush Street, Baltimore, Maryland, specialists in dredging outfits, are equipped to furnish you with well designed hydraulic dredge, either diesel, electric, gasoline or steam driven, built for efficient and economical service. Mr. C. E. Ellicott, Jr., will be pleased to furnish you full information concerning outfits for jobs of all sizes. If you will mention this magazine, he will send for your convenience a hydraulic dredge capacity indicator.

Steel.—Write to the Inland Steel Company, 38 South Dearborn Street, Chicago, Ill., for information regarding their Inland Copper Alloy Steel Sheets, made for resisting corrosion. State your requirements and particulars will be given to you on sheets, bars, plates, shapes, rails, track accessories, rivets, billets, etc. If writing for literature, kindly give the name of our publication.

Pumps, Engines, Hoists.—If you have hoisting problems, write to Mr. Clarence E. Bement, of the Novo Engine Company, 200 Porter Street, Lansing, Michigan, asking for a free copy of Novo Hoisting Handbook. This is not a catalog but a book of useful information for the man who must meet hoisting problems. They will also be glad to send you full particulars concerning their entire line of products.

Lumber.—For the users of lumber, the National Lumber Manufacturers' Association, Transportation Building, Washington, D. C., has much valuable information in booklet form, which they will be glad to send you. Bulletin No. 16 is called "Simplified Practice" and another booklet containing much general information is called "Information on Lumber and Where to Find It." Either of these booklets will be sent without obligation by addressing the company at Dept. 4651, at the address given above. If applying for a copy, kindly use the name of our magazine.

Slackline Cableway.—"Excavating for Profit" is the name of a booklet issued by Sauerman Bros., Inc., 428 S. Clinton St., Chicago, giving many instances of work done by a Sauerman machine which presented problems to the contractor to know how to handle the job at a profit instead of a loss. We would appreciate the use of our name if writing for a copy of this booklet.

Mast Hoist.—The Insley Manufacturing Company, Indianapolis, Indiana, invite your inquiries in regard to the results obtained by the use of their mast hoists. This piece of equipment handles concrete with the buckets and chutes, and also hoists miscellaneous material with a material elevator operating independent of the bucket, and with a boom handles such material as reinforcing steel which is too long for an elevator. Write for literature giving complete information on this machinery. Mention of this magazine would be appreciated.

Governors.—How to increase production and profits and lower operating costs, by the use of Pierce Governors, is described in Booklet No. 14, issued by the Pierce Governor Company, of Anderson, Indiana. This equipment on power engines results in a smooth, uniform flow of power to meet every load. Fuel, operating and repair bills are reduced and the life of engines prolonged. Mr. D. J. Nolan, of the Pierce Governor Company, will be pleased to send you a copy of this booklet, and we should be pleased if you would mention our magazine when writing.

Cranes - Shovels - Draglines. — The Koehring Company, of Milwaukee, Wisconsin, manufacturers of pavers, mixers, gasoline shovels, cranes and draglines, would be pleased to send you detailed information concerning their heavy duty construction equipment. This company emphasizes the service which goes with all sales of their equipment, and their sales offices and service warehouses are located in all the principal cities. Kindly mention the name of our publication if writing Mr. O. C. Dahlman of the Koehring Co., for literature on this equipment.

Tractors.—Caterpillar Tractor Company, San Leandro, Calif., will be pleased to send you literature on how to spread your profits by the use of their caterpillar track-type tractors and tracks so that the bull-doze blades can be run up to the very edge of dumps, spreading and filling in as fast as the earth is dumped. Write for information, mentioning this magazine.

Shovels-Draglines-Cranes-etc. — The Osgood Company of Marion, Ohio, makers of pile drivers, cranes, clamshells, shovels, draglines, back hoes, etc., will be pleased to have you write them, giving your requirements. They will furnish you with full information to meet these requirements without obligating you in any way. When writing give the name of our publication.

Electric Calculator.—For the man who has to figure, the Burroughs Electric Calculator offers lightning like help in checking stresses and strains, dimensions, areas, cubic content, estimates, payrolls, costs or other calculating. Write to the Burroughs Adding Machine Company, Detroit, Michigan, attention of Mr. H. J. Boone for further information about this electric calculator. If you will mention our magazine, it will be appreciated.

Shovels.—Gasoline, steam or electric powered shovels, cranes, draglines and backdiggers manufactured by the Thew Shovel Co., Lorain, Ohio, will be described to you in detail, with stories of what they have accomplished, if you will write for particulars to Mr. Joe Selzer, c/o The Thew Shovel Company, giving the name of this magazine.

Explosive.—For lowering blasting costs the Hercules Powder Company advise that you investigate without delay the results accomplished by the use of Hercomites. Full information concerning Hercomites No. 2 to No. 7 will be sent if you will write to Mr. N. S. Greensfelder, Hercules Powder Company, Wilmington, Delaware, mentioning this publication.

Cement.—Of interest to the cement users is the new booklet issued by The Universal Portland Cement Company, called High Early Strength Concrete. This booklet gives full details for securing strong concrete in three days with the usual materials and labor. Write to Mr. Charles S. Rye of the Chicago office of the Universal Portland Cement Company for a copy of this booklet. We would appreciate your mentioning our magazine if writing.

Electric Power.—A very attractive forty-eight page booklet, well bound and profusely illustrated, is now being distributed by the Electric Machinery Manufacturing Company of Minneapolis, Minnesota. It is devoted to the subject of power factor correction with capacitors (static condensers). The title of the book is "Reducing the Cost of Electric Power" and gives a non-technical explanation of power factor and shows when and how to apply capacitors to reduce electric power cost. It also explains the construction of capacitors. This company has offices in all the principal cities where copies of this book may be secured, or from their main office at Minneapolis.

Cranes, Clamshells, Draglines, Skimmers, etc.—Write for Bulletin 45-D if desiring full information regarding the Universal-35, the new ½-yard machine of the Universal Crane Company. This is the 2-speed center drive crawler, a powerful rope crowd center drive shovel, readily convertible to crane, clamshell, dragline, skimmer, and backdigger. There is no obligation on your part in asking for this bulletin, just write to Mr. J. L. Beltz of the Universal Crane Company, 1324 E. 28th Street, Lorain, Ohio, for a copy, mentioning the name of our magazine.

Portable Flasher.—The Eveready Portable Flasher, is manufactured by the National Carbon Co., Inc., and when operated continuously the Columbia Dry Batteries should last two months. This is because the intermittent character of the load has been calculated to get the longest possible service from the battery. The operating cost of the Eveready Flasher is low, and the only attention required is the changing of batteries every two or three months. The National Carbon Company has offices in the principal cities, or they will be pleased to receive your inquiries at their New York office, 30 East 42nd Street, and will send you complete information in regard to this serviceable warning signal. If writing kindly give the name of our magazine.

Bituminous Heating & Distributing Unit.—Catalog KHD, issued by the Good Roads Machinery Co., Inc., Kennett Square, Pa., will give you complete details concerning their new Champion Bituminous Heating and Distributing Unit, for the application of asphalt and tar products. Write for description of this piece of equipment and then look it over at the Road Show. In addition to catalog KHD this company has a new catalog on sand and gravel KSG. Both of these catalogs will be found very helpful to persons interested in these fields. Booklets are profusely illustrated and contain useful tables. If writing for copies, please mention our magazine. Mr. J. W. Kitts is advertising manager and will be pleased to see that this literature reaches you.

Rock Drills.—The new Sullivan Rotator "L-8" is fully described in their new Bulletin 581-T. Write to Mr. S. B. King of the Sullivan Machinery Company, 76 East Adams Street, Chicago, for this booklet. The "L-8" features automatic rifle-bar rotation of the bit; improved steel retainer; automatic lubrication; automatic ejection of cuttings from drill hole; cushioned return stroke; adaptability to use on mountings; simplicity and convenience; drilling speed and power. Selected steels and Sullivan standard workmanship are employed in the perfection of these drills. If writing to Mr. King for information kindly refer to our magazine.

Calcium Chloride.—The Solvay Sales Corporation, have for free distribution a book on the use of calcium chloride in concrete construction. Their product, Solvay Calcium Chloride, is recommended for making stronger and denser concrete in any weather, but particularly for construction in freezing weather to insure profitable work. Much practical information is given in Booklet 6553. It is yours for the asking. Mr. A. T. E. Newkirk of the Solvay Sales Corporation, 40 Rector Street, New York, will be pleased to send it to you. If writing to Mr. Newkirk, kindly mention our magazine.

Asphalt.—The National Asbest-O-Phalt Corporation located in the Builders Building, Chicago, places the services of their engineering department at the disposal of architects, contractors and engineers for the purpose of investigating the uses of Asbest-O-Phalt in its many forms. There is also an office in New York to serve the eastern territory and one in San Francisco for the far west, as well as offices in London and Paris, for information concerning this modern chemical development of a product comparable with the natural asphalt of the ancients. If writing or consulting the National Asbest-O-Phalt Corporation we will appreciate it if you will give the name of our magazine.

Excavating.—A limited edition of a copyrighted piece of literature called "Excavating in Pre-Drained Wet Soils" is yours if you care to write to the Domestic Engine & Pump Company, N. Queen Street and P. R. R., Shippensburg, Pa., and request that a copy be sent to you. This booklet contains valuable information for engineer and contractor. We would appreciate it if you would mention our publication when writing for a copy.

Tractors.—Literature on the Atlas 4-wheel drive and 4-wheel steer tractors will be sent to you without obligation if you will write to Mr. C. W. Zimmerman, c/o The Atlas Engineering Company, Clintonville, Wis., mentioning our magazine. Particulars as to construction and performance will be furnished. This tractor is particularly well adapted for climbing hills, crossing ditches and pulling stumps and other heavy loads.

Floor Plates.—A new bulletin is now available describing the service of the Central "Knobby" Non-Skid Floor Plates, manufactured by the Central Iron & Steel Company, Harrisburg, Pa. These plates will stand the wear and tear of the most constant traffic. This company has offices in the principal cities, where information can be secured, or by writing direct to Mr. L. F. Nagle, Central Iron & Steel Company, Harrisburg, Pa., using the name of our paper.

Cresolac.—This is a transparent waterproofing preparation for brick, concrete, stucco, stone and plaster surfaces, and can be used without stain or discoloration. For full information concerning this product write to the Ceresit Waterproofing Corporation, attention Mr. F. A. Mitchell, 512 So. Canal St., Chicago. We would appreciate mention of our magazine if writing for particulars about this product.

Dredges.—Catalog E issued by the Norbom Engineering Co., Darby, Pa., gives full particulars concerning the Norbom Hydraulic Dredges. These dredges will be built to suit your special requirements. Write for a catalog giving the name of our magazine.

Textured Tile for Building.—The Clay Products Company, Inc., of Brazil, Ind., has just issued a very beautiful as well as authoritative text book on textured tile. It is a 60-page catalog, in loose leaf style, with cover and inside plates in nine colors. In presenting this catalog for the consideration of architects, engineers and builders, Mr. E. C. Gaertner, sales manager for the Clay Products Company states: "Textured tile is really a new type of building material, and we felt that architect, engineer and builder were entitled to a thorough treatise on the subject. We believe this is the most elaborate work of its kind that has ever been published." As rapidly as this field develops, additional pages will be sent to all the owners of the catalog to keep it up-to-date, which was the purpose in adopting the loose-leaf style of binding.

Bags.—Let the Bates Valve Bag Corporation, 35 Wacker Drive, Chicago, tell you about their multi-wall-paper bags in a very attractive folder which they have recently issued. These bags are proving of inestimable value to the contractor in protecting his plaster from losses by the elements. This company also manufactures the Bates Ties and Tools for the use of contractors in speeding up reinforced concrete work, by fast, tight, non-slipping ties requiring no special skill to apply. Write to this company for their latest literature, mentioning the name of our publication when writing.

Inertol.—This is a waterproofing and anticorrosive compound for impregnating concrete surfaces and for protecting steel, making the structures waterproof under pressure and immune against aggressive chemicals. This is manufactured by the Inertol Company, Inc., 253 Broadway, New York City, and stocks are carried in Newark, N. J., Chicago and San Francisco. In color it is a glossy black and comes ready for use, and needs no skill in applying, but is used cold with brush or paint sprayer. An illustrated broadside has just been received from this company giving the many uses for this product, prices, etc. Write to the manufacturer for full information, mentioning this magazine.

SAVE YOUR TIME! USE OUR SERVICE! Prices on equipment, names of manufacturers or their catalogs will be cheerfully furnished to you by our Service Department. Write Municipal News and Water Works, 221 E. 20th St., Chicago.

Operating Experiences With California Water Purification Plants

How Problems at East Bay Water Co. Plants Were Solved

By WILFRED F. IANGELIER

Associate Professor of Sanitary Engineering, University of California, and Consulting Sanitary Engineer, East Bay Water Co., and

JOSEPH D. DECOSTA

Assistant Sanitary Engineer, East Bay Water Co.

THE East Bay Water Co.* supplies water to Oakland and Berkeley, Calif., and other adjoining municipalities on the east side of San Francisco bay. The average daily consumption of water for 1927 was 32,000,000 gal., approximately two-thirds of which was filtered water from surface sources. There are two major filtration plants, the San Pablo plant, located just north of Berkeley, and the Upper San Leandro plant, 15 miles to the southeast in Oakland.

Raw Water Supplies.—Both plants are supplied with impounded waters of practically identical composition. The watersheds lie adjacent to one another and are of similar physical character. In general these waters are characterized by moderately high organic and mineral content and the reservoirs are subject to heavy growths of plankton or algae. The turbidities are flashy. During the heaviest run-off season, usually in February, the raw waters may attain turbidities of 2,000 or more p.p.m. Two weeks later the turbidities may have dropped to 25 p.p.m. and may not rise above this value for a full year.

The soluble and colloidal organic matter, mostly of vegetable origin, is continuously high. This is indicated by oxygen consumer values of approximately 10 p.p.m. and color of 40 p.p.m. A chlorine absorption test made recently gave a result of 70 lb. per million gallons, equivalent to 8.4 parts per million. These raw waters are capable of absorbing chlorine gas to upwards of 20 lb. per million gallons without causing taste or odor. That some of the organic matter is in colloidal suspension is indicated by the fact that the filtered water, although apparently clear, shows a marked Tyndall effect. It is practically impossible, with the use of ordinary alum dosages, to reduce the color to less than 15 parts per million.

The hardness of either water is slightly greater than its alkalinity and averages 3.5 milli-equivalents per liter or 175 parts per mil. The equivalent Sodium-Magnesium-Calcium ratios are approximately 1.0, 1.25, 2.25, and the Chloride-Sulphate-Bi-Carbonate ratios 0.75, 1.0, 2.75. The reaction of the water is slightly alkaline, pH=7.6.

The watershed lands that produce run-off water of this character are only sparsely wooded. Possibly 25 per cent

*The properties of the East Bay Water Co. have been taken over by the East Bay Municipal Utility District, which now operates them.

of the land is forested. The top soil is mostly clay. The lands are 70 per cent owned by the company and the density of population is very low, so human pollution is a negligible factor in the purification process. In 1927 only 10 per cent of 1,200 ton c.c. portions of raw water tested were found positive for M.R.+organisms of the Colon group.

Other characteristics of the raw water which relate to the problems of purification are the seasonal presence of Plankton growths, more particularly the blue-green types of floating algae, and traces of Manganese, both of which may be very troublesome in connection with filtration.

Plankton Growths.—In this region, plankton or algae, if permitted, may grow abundantly the year around in practically all storage and open distributing reservoirs. In our storage reservoirs, where in many instances not more than 50 per cent of the water is replaced annually, the growths may be exceptionally heavy. Throughout the winter and spring months the plankton consists most of Crustacea and Rotifera and seldom exceed 10 p.p.m. by volume. Beginning in May or June, however, the sudden development of certain forms of Cyanophyceae may exceed 39 to 40 p.p.m., and if not controlled, may remain until October or November. Peak growths as high as 200 p.p.m. have occurred.

It has not been the practice to treat these stored waters with copper sulphate. The cost of such treatment, if given frequently in reservoirs holding upwards of five billion gallons, would be considerable, and since even the Blue-Green algae do not produce tastes and odors which survive the treatment process afforded these waters, coppering, up to the present time, has not been considered necessary.

In addition to the Crustacea which are present in varying density throughout the year, the predominating and most characteristic organism in the storage reservoirs is the Blue-Green alga Apanizominon. This organism has made its appearance each year and when the growth is at its peak a scum forms on the quiet waters around the margin of the reservoir which in places may be ¼ in. thick. Away from the shore the large masses are broken up by wave action, but the characteristic tiny clusters may be seen with the naked eye. Although this organism is reputed to impart to water a characteristic grassy taste and odor, our experience indicates that in the supplies under consideration taste and odor production is negligible until the organisms are undergoing decomposition. At such times the moldy odor, commonly associated with decay of vegetable matters, is usually noted. During periods of heavy growth, the removal from the water of the organisms themselves may add a heavy burden to the filter units. This burden is considerably lessened by excluding, from entrance into the intake, waters from the upper strata of the reservoir. These organisms do not penetrate, in large numbers, depths below 25 ft. except on very windy days. Treatment of the water at the intake with chlorine kills the organisms, but such treatment has not proven to be an advantage. Only a small portion of the organisms either dead or alive can be removed in the sedimentation basins after coagulation. When these growths are heaviest, the salvaging of the wash water from the filters, as ordinarily practiced, is dispensed with.

In the uncovered distributing reservoirs much algae trouble has been experienced in the past. We have found that during the summer and fall months dosing with copper sulphate, at regular intervals of about four weeks, is essential to the elimination of taste and odor complaints. Such treatment, moreover, not only prevents the periodic development of taste producing algae, but improves the appearance of the water by the destruction of brownish nannoplankton which otherwise would be present almost continually. It appears also that these treatments exert a cumulative effect in reducing materially the larger aquatic vegetation which formerly developed in some of the larger reservoirs. The elimination of nannoplankton requires a rather large dosage of copper sulphate. On a few occasions we have added as much as 15 to 20 lb. per million gallons of water. It seems that copper sulphate is less toxic to these smaller organisms. The effectiveness of chlorine in the destruction of

bacteria would indicate the possibility that such treatment would be more effective than copper sulphate in the destruction of these smaller algae, but we have, as yet, no conclusive data on this matter.

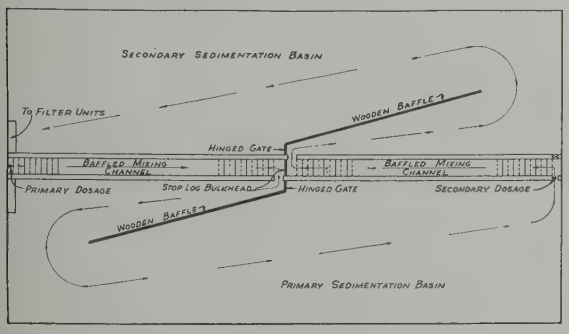
Filter Sand Troubles.—Within a few months after the San Pablo plant was placed in operation in 1921, a dark brown or almost black discoloration of the sand grains in the filter units was observed. This indicated the possible presence of manganese in the raw water and analyses confirmed this suspicion. The manganese content was found to be quite small, however, being somewhat less than one-tenth of a part per million. Realizing the damage that might result from permitting a manganese-bearing water to enter the distribution system, and also realizing the effectiveness of manganese-coated sand in removing manganese from water, it seemed desirable not to interfere with its further deposition. The discoloration and subsequent incrustation of the sand began at the top of the bed, where lay the finest sand, and gradually worked downwards. The first indication of any unfavorable effect was observed in connection with filter washing. The incrusted sand showed a marked tendency to cake, thereby causing the wash water to jet through the sand unevenly. In the course of a few months it became necessary to thoroughly prod the beds with rakes while admitting wash water. The condition of the sand kept getting worse until, in the summer of 1923, two years after beginning plant operation, under water cracking of the sand beds in very serious form occurred. At this time the upper 6 in. of sand had accumulated a heavy coating, equivalent to 20 per cent by weight. The amount of incrustation decreased with depth, averaging only a little over 1 per cent for the bottom 6 in. Analysis of the dried incrustation showed it to contain: Organic Matter 60 per cent, Aluminmum Oxide 26 per cent, and Manganese Dioxide 11.5 per cent. Describing this condition at the time, it was stated:

"The incrustation as found on the sand grains when a filter is drained is heavily hydrated, and when the sand is compressed in the hand the feel is like that produced by squeezing a handful of granular cork or rubber. The wet sand is also very plastic, so much so that a rod forced into the sand to the gravel layer, upon withdrawal will leave a perfect impression. If the wash water is then turned on, a jet will be formed at this point."

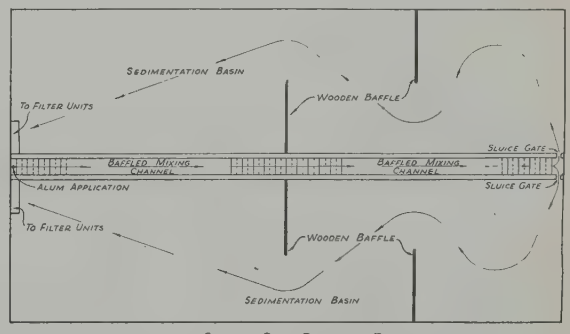
Much has been written concerning filter sand incrustation and filter bed cracking, which is sometimes associated with it. Our observations lead us to believe that filter sand incrustation may develop regardless of the character of the sand, provided the water is of a certain character and contains essential constituents, as for example, traces of manganese, colloidal calcium carbonate, suspended organic matter, etc.; and that cracking may occur if the coated sand is sufficiently compressible and subject to vertical stratification with relatively incompressible clean sand from underneath and brought to the surface by the jetting action of the wash water. We believe that the cracks are formed by unequal settlement of the sand bed, and that having once formed are subject to enlargement as a result of lateral compression of the vertical filtering surfaces. The correctness of this theory was indicated by frequent examinations of the sand on opposite sides of a crack and also from the observation that when a filter was drained immediately after washing, small cracks were formed upon standing, and always in a plane of vertical stratification.

It occurred to us that a system of washing more effective than the high rate water wash and the temporary experient of hand raking would be desirable. These units are designed with perforated pipe underdrainage and it seemed a very simple matter to adapt them to supplementary air agitation. It was assumed that a preliminary blowing of air through the bed would loosen the compacted sand and permit of a better wash water distribution.

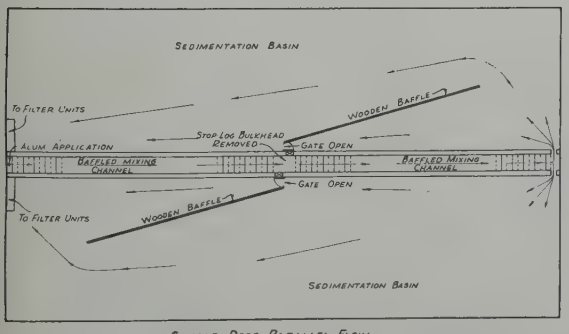
Accordingly, a complete unit was dismantled, the laterals carefully leveled, and the central manifold tapped to admit air. This unit was operated through a full season with excellent results and complete freedom from cracking. The following year the remainder of the units were treated in a similar manner. Since the introduction of air applica-



DOUBLE-DOSE SERIES FLOW OPERATION



SINGLE-DOSE PARALLEL FLOW



SINGLE-DOSE PARALLEL FLOW

Diagram Showing Alterations to Coagulation and Sedimentation Unit of San Pablo Filtration Plant

tion preliminary to the water wash, we have not once observed any cracking of the sand.

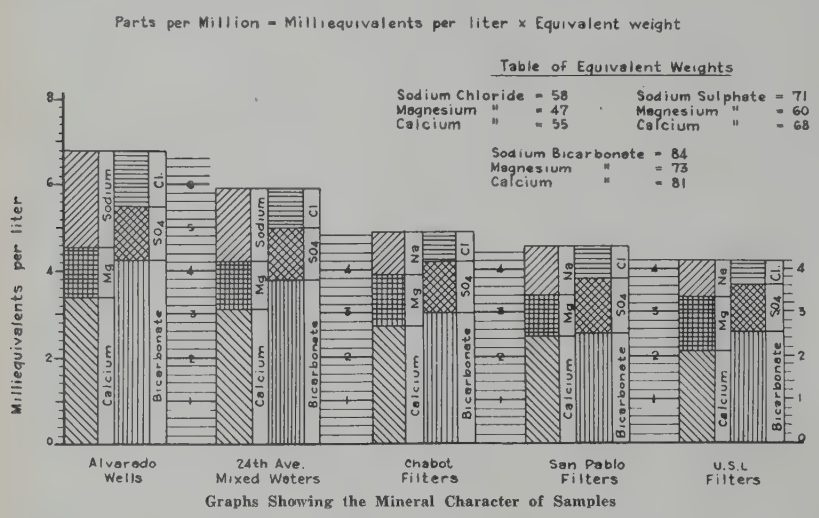
With this experience as a guide, the newer Upper San Leandro plant was designed for both preliminary air application and high rate water wash. We are convinced that air application is a cheap and effective method of preventing filter troubles caused by sand that has become plastic through coating of the grains. We have observed that the application of air in this manner does not materially agitate the sand. Its effectiveness depends upon a mere piercing of the plastic sand directly above each orifice such that the water may loosen subsequently the entire bed.

In this connection, it should be noted that the successful distribution of air through perforated pipe drainage laterals requires that they be set perfectly level. Studies made with separate laterals submerged under water showed that a difference of elevation of ⅛ in. at the opposite ends of a 14-ft. lateral was sufficient to impair distribution.

In the matter of manganese deposition, however, we are still perplexed with at least one phenomenon. Whereas at the San Pablo plant the fine sand at the top of the bed was the first to become coated, at the Upper San Leandro plant the gravel became coated before any of the sand was affected. We are unable to explain this definitely at the moment, but we suspect that it has to do with bacterial activity influenced by oxygen potential. In the latter plant the admission of air preliminary to washing may have been sufficient to maintain aerobic conditions in the gravel layer. At the San Pablo plant a gradual depletion of the dissolved oxygen content of the water, as it passes through the sand bed, indicates aerobic activity in the upper sand layers where the deposition occurs. One other condition surrounding these experiences is the fact that at the San Pablo plant the gravel was found to be quite heavily incrusted with iron oxide resulting from corrosion of the steel underdrains. It is well known that manganese oxides are not readily precipitated in the presence of ferrous iron. At the Upper San Leandro plant the underdrains are of brass tubing and iron deposits in the gravel are absent.

Salvage of Soiled Wash Waters.—The high cost of raw water development in this locality is such as to warrant the salvaging of soiled wash waters. This is accomplished at both plants with the use of suitable storage basins and pumping equipment. At times of excessive plankton growth, it is necessary to waste some of these waters for short periods each year. We estimate, however, that upwards of 95 per cent of these waters are redeemed, and this at a very considerable saving in water development costs. Throughout the greater part of the year the quality of this water after sedimentation compares very favorably with that of the original raw water. We believe that the ideal basin should provide a capacity equal to the wash water production for 24 hours, the return of the water to be distributed over a period of about 12 hours.

One item of interest in this connection relates to the problem of preventing accumulations of Crustacea which are not removed by sedimentation and are not easily destroyed with an algaecide. For a time this gave us some trouble until we hit upon the idea of their destruction on the filter beds by desiccation. This is accomplished by draining the filter unit and keeping it out of service for several hours. After such treatment the dead organisms are easily removed by sedimentation in the storage reservoirs. Where filter capacity is limited, it is believed that spraying the drained filter surface with an algaecide would accomplish the same result instantaneously; we have not, however, had occasion to give this a trial.



Graphs Showing the Mineral Character of Samples

Coagulation and Sedimentation.—The San Pablo plant as originally designed and built was found to be somewhat inadequate with respect to coagulation and sedimentation facilities. It was found that the highest turbidities occurring from three to four weeks each winter could not be lowered to the point of yielding a perfectly clear filtered effluent, even when the plant was operated at one-half capacity. This is believed to have been due to a variety of causes.

The coagulation and sedimentation unit as originally designed comprised two rather long rectangular basins, separated longitudinally by a shallow mixing channel, equipped with the usual "over and under" type of wooden baffles. The arrangement was such that the sedimentation basins could be operated only in parallel. Short circuiting occurred in these basins to an abnormal extent, due partly to the absence of suitable and properly designed inlet and outlet facilities. Wing baffle walls were first experimented with, but the results were not altogether satisfactory. Later, laboratory experiments indicated the desirability of double coagulation and sedimentation for the preliminary treatment of this water. In 1924 the basins were temporarily equipped to operate in this manner. The results were so satisfactory that permanent alterations were later made.

The problem of converting the existing parallel flow basins into series flow with double treatment and mixing was solved in what we regard to be a rather unique and highly satisfactory arrangement. This can best be visualized by reference to the accompanying sketches.

The mixing channel was blocked off at the middle point. On opposite sides of this bulkhead and in opposite walls of the channel an outlet weir into each basin was made. Opposite these outlet weirs, and somewhat diagonally toward opposite ends of each basin, a wooden baffle wall was installed. With this arrangement the water is given a primary dosage of alum, after which it flows through one-half of the total length of mixing channel, is diverted into the primary settling basin, through which it flows in a gradually retarded velocity into the far end of the mixing channel, where it receives a second dosage of alum. The water then travels back through the secondary mixing channel toward the center of the unit, over the second outlet weir into the secondary settling basin, in which the path of flow is identical to that in the primary basin. Conversion of the unit to single dosage and parallel flow is accomplished by removal of the channel bulkhead and by closing the adjacent weir openings with stop logs, so that the water may travel directly to the far end of the channel. At this point in each wall a large weir has been installed to replace the original 24 in. sluice gates. A simple adjustment of each baffle wall, made possible by a

free hinged end, has the effect of converting a portion of each basin into two parallel flow compartments. Experience indicates that the baffles in this position are desirable in that they assist in preventing transverse currents.

These simple alterations were carried out at very small cost and have had the effect of greatly increasing the efficiency and capacity of the whole plant, especially during periods of high turbidity.

Tests of normal operation this past winter showed that with a raw water of 1,000 p.p.m. turbidity, a clarification efficiency of 90 per cent was obtained in the primary unit, and 80 per cent in the secondary unit, making a total reduction of 98 per cent, resulting in an applied water turbidity of 20 p.p.m. The alum dosages in the two units were 4 and 2 grains per gallon respectively. Unfortunately, at this plant the total available mixing period at normal capacity of the plant is only 10 minutes. A longer period would undoubtedly produce a more rapidly settling floc with a smaller alum dosage. This fact is indicated by laboratory experiment and from our experience in operating the Upper San Leandro plant, where a mixing period of 25 minutes is provided. This latter plant has been in operation but little over a year. It was designed with the San Pablo experiences in mind and we are pleased to say that it is functioning excellently and in complete accordance with our expectations.

Circular Coagulation Tanks at Upper San Leandro Plant.—Circular coagulation tanks with mechanical stirring, used originally at Sacramento and in a slightly modified form at this plant, constitute perhaps the most interesting feature of design. These units differ from the Sacramento units more particularly in the matter of the ratio of paddle width to tank diameter. In the Sacramento design this ratio is 0.9, whereas in the Upper San Leandro plant the ratio is 0.24.

Paddles of this type have a lower starting torque and permit of much lower gear reduction. They are particularly well adapted to small units, since in these the paddle tip velocities are not excessive. Studies of these ratios with respect to hydraulic characteristics and other operating features are in progress and will be discussed in a later paper.

The high coagulation and sedimentation efficiencies at the Upper San Leandro plant are an important factor in reducing the burden on the filter units to a minimum. The average dosage of alum used at this plant for the entire first year of its operation was .89 grains per gallon as compared to 1.73 grains per gallon at the San Pablo plant. Applied water turbidities moreover were lower, averaging 10 and 15 parts per million respectively.

The mechanical mixing devices and exceptionally large waterways at the Upper San Leandro plant permit of a practically neglibible loss of head in the coagulation and sedimentation basins. Actual measurement at the rated capacity of the plant shows this loss to be only 1 in. The San Pablo loss of head with present baffling is 16 in., which at actual cost of pumping of 7 ct. per foot, per million gallons, would be $1.13 per day for the rated capacity of the plant. Electrical input at the Upper San Leandro plant for the four units is 3.6 hp., equivalent to $1.03 power cost per day also based on the same and actual rate for power. Although the costs are roughly equal, it should be noted that the mechanically operated units provide a retention period 2.5 times greater. Moreover, the mean velocities in these units are higher, averaging 1.3 ft. per second as compared to 0.8 ft. per second for the gravity mixing channel.

Chlorination.—All filtered water is chlorinated, primarily as a safety measure, because even the raw waters fall within the U. S. Public Health Service Standards throughout most of the year. The dosages vary from 2.5 to 8.5 lb. per million gallons and are controlled by frequent Tolidin tests. Our operators try to maintain between 0.50 and 1.00 lb. of residual chlorine per million gallons, ten minutes after application.

One ton chlorine cylinders have been in use since November, 1926, and we believe them to be the safest, cheapest and most reliable form of container for plants or groups of plants within a trucking radius of each other using a minimum of about 30 tons of chlorine per year.

Acknowledgment.—The above is an abstract of a paper presented at the San Francisco convention of the American Water Works Association.

Proper Disposal of Farm Sewage Important to Health.—Farmers' Bulletin No. 1227-F, entitled "Sewage and Sewerage of Farm Homes," reissued recently by the United States Department of Agriculture, warns against the dangers to human health and to livestock of negligence in properly caring for all forms of farm sewage. Details and illustrations are given for construction of approved privies, chemical closets and septic tanks. Suggestions are also made for the proper placing of them on farms so they will not drain toward wells. The use of disinfectants and deodorants is also explained. Proper care of the kitchen sink drainage is urged and illustrations show methods of disposal. The placing and construction of cesspools and grease traps are also discussed. Methods and details of construction are explained and illustrated in such a way as to be understood by homeowners. Copies of the bulletin may be obtained by application to the Office of Information, United States Department of Agriculture, Washington, D. C.

Pipe Line Inlet Air Valves

By J. W. LEDOUX
Consulting Engineer, Liberty Trust Building, Philadelphia, Pa.

In the July, 1926, issue of Water Works, the writer presented a paper on "Pipe Line Inlet Air Valves." Two very important experiences—one occurring in 1922 and the other during 1928—are convincing that there is a vitally important application of inlet air valves, or equivalent, that was not suggested in that paper.

The first experience was a number of serious breaks that took place on a 36-in. line, the cause of which was diagnosed as "water-hammer" due to a draft on the pipe line at a low point at a greater rate than the pipe capacity on the flatter grade above, causing the pressure on the flat grade to be reduced below the atmosphere, and the consequent parting of the column of water. When the draft on the line decreased, the upper column of water came in contact with the slower column of water in the lower part of the line, causing an enormously increased pressure, which broke the pipe. This experience was repeated five times within a year, and the pipe broke at different places not more than half a mile apart.

The remedy suggested was a surge tank at the point where the grade changed, and after this was installed no further breaks took place.

The writer was called in on a very similar experience in another part of the country where a 36-in. main had broken six times within four or five months. He diagnosed the cause to be the same as previously, and in this case, to avoid expense, advised combined automatic inlet air valves and outlet air valves. The first was to let in air as soon as the pressure was reduced to the atmosphere, which would provide an air cushion to prevent diastrous increase of pressure due to two columns of water coming together. The outlet air valves were necessary to relieve the line from air and permit the normal flow to be maintained.

This application of automatic inlet and outlet air valves is extremely important and they should be installed in a great many places where such conditions are possible, and may save the immense cost of surge tanks.

New York City Has 16 Garbage Incinerators.—New York now has 16 garbage incinerators in operation, located: three in Manhattan, two in Brooklyn, eight in Queens, and three in Richmond; three more are under construction in Brooklyn, and four more new incinerators were approved by the board of estimate and apportionment in November. It is expected that upon the completion of all—a total of twenty-three plants—the dumping of the city's garbage at sea may be entirely eliminated.

Cleaning a Water Main

Ice Plugs Used to Remove Soft Substance

By G. E. SHAW
Manager Chilton Hills Spring Water Co., Aylesbury, England

WHEN carrying out repairs or alterations on a public water supply system, the difficulties encountered are usually increased by the fact that, if the supply be curtailed, even to a slight extent, some of the consumers will lodge complaints. Perhaps, therefore, an account of a problem which had to be solved, without interfering with supply, by the Chilton Hills Spring Water Co. will be of interest.

Recently it became necessary to clean a length of 14-in. main which had become considerably choked by deposit. The main, which is shown in plan and profile in Fig. 1, runs from a service reservoir A to a point K, some 1¾ miles across country. All the water passing into the service reservoirs A and B is previously softened by Clark's lime process, and sometimes the water coming from the softening tanks is slightly grey, owing to the presence of minute particles of a flocculent nature. These particles, which have a specific gravity practically the same as that of water, remain in suspension in the water until they touch the walls or columns, when they appear to adhere to them tenaciously, but do not harden. The particles which are not arrested in this manner, enter the 14-in. main, and when they touch the sides of the pipes they adhere to them. In that way the main had become much clogged.

It was at first thought that the heaviest deposit was in the low-lying portion of the main, near the point F in the drawing, and in the hope of removing it, a wash-out had been inserted at the point K at the far end of the main. Although, however, that valve discharged the water faster than the main could bring it down, no great amount of deposit was washed through, which was taken to show that the deposit was in the upper part of the main, that is, between the points F and A, and that other measures would be required to remove it.

As a commencement, a 1-in. gas tapping hole was bored in the main at E, and on inserting a candle on a wire into that hole, it was found that the interior of the pipe was coated evenly all around to a depth of 2½ in. with a soft chalky substance.

It would, of course, have been possible to remove the deposit by means of the usual type of scraper, but there was hesitation in using a scraper, for, in the event of its sticking, the water supply of the whole system would have been cut off until it was removed. As the main was, in some places, as much as 16 ft. below ground level, it would have been a lengthy undertaking to open the ground and cut out the scraper if it happened to stick in any of those places.

It was therefore decided to clear the main by using plugs of ice which would melt if they did happen to stick. The main was, accordingly, cut at the points E and G, and a hatch-box was inserted at each place, a 14-in. valve being at the same time inserted at H. The point G was chosen for the insertion of a hatch-box, as it was a little way up a hill side, and, by cutting a channel at the lower end of the excavation, water and debris issuing from the hatch-box could be discharged into a valley at the foot of the hill, so that no pumping would be required to keep the excavation clear of water.

It may be explained that, before starting operations preliminary experiments had been carried out at the works with a short length of 10-in. main. A 10-in. diameter plug of ice, which had a 1-in. diameter hole formed through it from end to end, was employed. The 1-in hole was formed because it was thought that it would be necessary to have a flow of water through the plug so as to wash away the debris as it was scraped off the sides of the main. It was found, however, that the flow of water through the hole speedily melted the ice, so that the plug became disintegrated in traveling some 200 ft.

For the actual work of cleaning the 14-in. main, it was therefore decided to use solid plugs, 14-in. diameter, and they were made 4 ft. long. There was a doubt at first as to whether (a) the debris scraped off the pipe would pack in front of the ice block and choke the pipe if the block were allowed to travel too slowly, or (b) on the other hand, the plug would melt quickly if allowed to travel too fast. It was decided, however, that it would be safer to let it travel faster rather than slower; but, as an aid to keeping down the temperature, and lowering the speed of melting, about 5 cwt. of broken ice were inserted in the pipe from each end of the hatch-box E. A 14-in. plug of ice, 4 ft. long, was then inserted in the hatch-box and the cover put on. The valve H had been closed and the cover of the hatch-box G had been removed while the ice was being inserted.

In order to carry out the work of clearing the main at a time which would cause the least inconvenience, operations were begun late one evening when the demand on the system was low. The valve at A was therefore opened at 10 p. m. As a result, the plug of ice was driven through the main to the hatch-box—a distance of over 3,000 ft. —in 10 minutes. After the water had been allowed to run through the main for a further few minutes, it was shut off, a second plug was then inserted in the hatch-box E and the operation repeated, the valve A being closed after a 20-min. flush.

It may be explained that when the main was cut to insert the hatch-box G the coating inside the pipe was found to be 1¼ in. all around, but after draining the low part of the pipe by means of the scour valve shown on the drawing, an acetylene lamp, passed along the main on tubing from G in the direction of F, showed the black of the Angus Smith coating for 300 ft.—the furthest distance that the lamp could be passed up the main—which proved that, for that length, at any rate, the main had been effectively cleared.

At 11 p. m. the valve F was closed, ice was inserted at G and the wash-out valve K and valve H were opened. While that was being done the main between F and A had become charged to its full pressure. The valve F was then opened, and the ice and debris was flushed through the valve K, a distance of nearly 5,000 ft., and discharged there, the operation being completed at 12:30 a. m. The whole length of the main from the reservoir A to the wash-out valve K was, therefore, cleaned in 2½ hours.

On visiting the site next day it was estimated that about 20 cart loads had been discharged at G—of which 14 cart loads were actually scraped off the grass and removed—and from 6 to 7 cart loads had been discharged at K. Judging from the portions of ice discharged, the writer arrived at the conclusion that 4,000 ft. is the maximum length that can be efficiently scraped by means of ice plugs, but that it would be possible to scrape a longer length by using a plug made of sugar of a similar consistency to that of hard boiled sweets, which would take much longer to dissolve than ice would to melt.

Acknowledgment.—The foregoing is taken from the Dec. 28 issue of The Engineer, London, England.

City Engineers' Problems Discussed at Cleveland Convention A. R. B. A.

Important Reports Presented by City Officials' Division

The Objects of the City Officials' Division

An Outline of What Is to Be Done

By CAPT. H. C. WHITEHURST
President City Officials' Divison; Assistant to Engineer Commissioner of Washington, D. C.

THE officials of the American Road Builders' Association, realizing the necessity for closer cooperation and greater standardization in the municipal highway field, organized on June 8, 1928, the City Officials Division. This division will doubtless fill the greatest existing gap in the highway industry.

It is through this division that municipal highway engineers will be afforded the opportunity to meet for an exchange of ideas and a study of new developments and methods. The advantage of conferring with manufacturers, contractors and others from every section of the country will be of inestimable value to all of us, and we trust every city official will endeavor to cooperate with us in our plan to improve municipal highway conditions.

It is my belief that every city should have a representative actively engaged in the work of this division.

Four Hundred Million Dollars Spent Yearly for New Paving.—The extent of the municipal highway activity is difficult to realize. No accurate figures as to the total yardage of pavements or improved streets covering all cities of the United States have ever been compiled. It has, however, been conservatively estimated that the total exceeds twenty billion square yards. Reports and estimates of new construction undertaken during 1927 indicate a total expenditure of over $400,000,000 for roadway paving, to which must be added $100,000,000 for maintenance. These figures do not take into account the expenditures for alleys, sidewalks, grading, roadway replacement and other municipal highway projects, such as street widening, bridges and grade crossing elimination projects.

Four General Committees.—The division has been organized into four committees for the work, as follows:

1. Organization, Administration and Finance.
2. Design and Construction.
3. Maintenance.
4. Traffic.

Each of these general committees has been divided into various sub-committees; however, for the first year, pending a survey of the municipal field and a broader acquaintanceship with those who will cooperate in the work, the general committee chairmen will develop the subjects for study by presenting at this convention an outline compilation of practices and thoughts for further study. The subjects under the several general committees cover practically the entire municipal highway and traffic field.

To me, however, under each of these committees there are outstanding features worthy of special consideration and thought mainly because of the past neglect, not only in the city I represent, in the city in which you are interested, but in 95 per cent of the other cities of the United States.

Organization, Administration and Finance.—Committee No. 1 deals with organization, administration and finance. I have found in my study of this subject that the methods employed in various cities differ to a marked degree. Of course, many of the methods are due to charter of state laws, and undoubtedly the systems in use serve in most cases, the purpose. There is, however, one neglected activity under study by this committee which is not controlled by basic laws and is vitally essential to the efficient and economical operation of any city street or highway department, no matter how organized or administered. I refer to cost records. You would be surprised to know that few cities of hundreds we have been in touch with keep any cost records, as we understand the term. Some have records of labor and material, but only a very few can give you accurate cost data of various operations. Without these, how can we compare methods, how can be say we are operating economically, or how can we be assured that we are getting the most out of our appropriations? Do we want to know? It may be like the man who owns an automobile; he doesn't want to know. Cost data are essential to the proper and efficient management of a municipal highway department; without it who can say when pavement and plant replacements are to be made or decide dozens of other questions? If such records were available over a period of years and the repairs of a certain kind were costing twice as much in Cleveland as in Chicago, your engineers would want to know why—without such figures, accurately and honestly made, we go pounding on in the dark. A uniform system is preferable so comparison may be made.

Such records would not only guide the engineer in maintenance work, but materially assist the designing and construction engineer in the selection and design of types of pavements.

Design and Construction.—Committee No. 2 deals with design and construction. Not to minimize the testing, research and experimental work that has been carried on in this field with inestimable value to every engineer interested in highway work, there is one, as important, but neglected subject assigned for study to this committee—field control and inspection. Associations, research bureaus, federal agencies and others have given us data for design and construction based upon scientific research and experiments that guide both the state and municipal engineer in the right path in this field; however, not one has put forward an educational campaign to insure the proper construction. Leaving for the moment mistakes in judgment and of sub-grade conditions, I dare say 90 per cent of other failures of streets and roads are due to poor inspections and lack of field control, or improper maintenance, the latter a subject I will touch upon. We carefully investigate the qualifications of applicant for design and field engineering positions, spend thousands of dollars in preparing plans and specifications, much time and thought in the testing and selection of materials, and then turn the work in the field for actual construction over to men who oftentimes fail to carry out either the spirit or intention of the work, either through incompetency or neglect. I have recently examined the paving specifications of some seventy odd cities. While there are provisions in some I do not agree with, there is not a single one if properly carried out that wouldn't insure a reasonable good pavement for the purpose intended. A relatively short time ago, I had the opportunity of visiting fifteen cities of the larger class and three state highway projects during the construction season. When I tell you that in eight of these cities there were no inspectors on the work, in four of them where inspectors were present they did not have nor had they seen the specifications, and in the remaining three, inspectors were present with the specifications but only two had read them, do we wonder why pavements fail. The state jobs were all well conducted with an inspector present and in each case he understood his work. These facts are almost unbelievable.

While I have for some time recognized the necessity and value of well trained inspectors, it so impressed me that I have given the subject since more thought than ever. Pavements are designed, specifications drawn and materials tested to provide and insure a predetermined strength in the structure. If construction is carried out in accordance with these instruments of service by the inspectors and engineers in the field, success will be attained in practically every case.

If men have to be employed in a city force for one reason or another, men untrained for the character of work in hand, incompetent or otherwise unsuited, don't put them in your inspection service, for if you do, the value of your engineers is partially destroyed and thousands of dollars invested in your construction jeopardized. Cities too small or whose work is not uniform so that they can maintain the nucleus of a good inspection force under a highly qualified chief inspector, would do well not to attempt to provide any inspection service but rather look to the established inspection bureaus for service, the services of which may be obtained at exceedingly low cost. Such service is vital to success.

Street Maintenance.—Committee No. 3 deals with the important subject of maintenance in all its branches. I am not going to attempt to go into detail on the operation of a maintenance division of a highway department, but I do want to bring out the importance of the necessity of keeping our streets in a high state of repair at all times, such being in the end the far more economical plan as well as providing better and safer traffic conditions.

Systematic maintenance with well defined policies will pull us out of the holes and result in far more economic operation, to say nothing of the comfort and convenience of the public. It takes a systematic procedure, a well balanced organization and sincere efforts. Do we want it? Is it worth while? The replacement value of paving and accessories of improved streets of the cities of the United States amounts to many billions of dollars—shouldn't such an investment be protected by proper maintenance—should highway maintenance, the right-of-way of the public, be carried on in a systematic and efficient manner the same as our principal railroads practice?

It is my belief that if sincere field control and inspection together with systematic and efficient maintenance were practiced today, failures of pavements would be reduced 90 per cent and in a few years result in large economy to municipalities. We condemn pavement design and materials unjustly instead of facing and stating our honest belief. I know of one city that has increased both the richness of mix and depth of base of the concrete for asphalt tops each year for the last three, attempting to prevent failure. Do you think the failure is due to design? What does the inspection cost?—probably less than 2 ct. per square yard, yet without any hesitancy the cost is increased 20 ct. per square yard by a change in specifications while everyone fears to increase the cost of inspection 1 ct. to correct the evil.

Traffic.—Committee No. 4 deals with the problems of traffic from many different angles. As a highway engineer, I am primarily interested from the standpoint of the use of streets, their capacity both as to volume and loads. The impression I have gained from my study of the traffic situation as related to a highway engineer's interest is the entire lack in nearly all cities of coordination of highway, traffic and public utility interests. The works of one are constantly upset by the works of another. There must be a closer and more cooperative spirit developed among these municipal activities if we are to succeed in our ultimate goal of service for the public. A highway system of a city may be likened to a railroad system in many ways. Where the arterial highways and main thoroughfares correspond to the main lines, the local or residence streets to the branch or secondary lines and the dirt or unimproved streets to sidings. In a railroad system each is constructed and maintained for the service intended. Is not the same applicable to a city highway system? To accomplish this, however, cities must zone or designate the street for use, design and maintain them for the service intended. Cities like railroads cannot, if for no reason than economic ones, construct all lines for maximum service and traffic. It is also true that railroad authorities design for certain classes of rolling stock which they control. So it must be with highway engineers or still greater losses may be expected.

If the City Officials' Division can accomplish no more than work out constructive suggestions for the benefit of cities to bring about the proper cost records, improvement in inspection service, systematic and adequate maintenance and a closer relation between traffic and highway authorities, it will have not only fulfilled its purpose and duty to the municipal authorities but will be the means of pointing out the way of saving millions of dollars to the taxpayers throughout our American cities.

Organization, Administration and Finance

Preliminary Report of Committee Presented Jan. 15 at Cleveland

By H. C. WHITEHURST

Chairman Committee on Organization, Administration and Finance, City Officials' Division

REPORTS, annual and special, were received from the highway departments of over sixty cities in the United States, and covered every state in the Union. They indicate many and varied methods of operation, administration, and financial procedure showing that to accomplish the same purpose there is no approach to standardization or the adoption of a uniform system. Due to this varying procedure, comparison is difficult. However, a compilation will afford a basis for discussion of the merits of the methods and will serve as an expression or guide to the sub-committees which may further develop the problem.

Six Major Subjects Considered.—The executive committee, after thorough study, tentatively divided the work of

the Committee on Organization, Administration and Finance into six major subjects as follows:

1. Organization.
   a—Cities of more than 300,000 population.
   b—Cities of less than 300,000 population.
2. Method of financing for new pavements.
3. Contract procedure.
4. Selection of types of paving and streets to be paved.
5. Financing and charges for street openings or cuts.
6. Cost records.

It is the intention of the executive committee to later develop each of these subjects through sub-committees, and to add other subjects which appear desirable.

Organization.—The organization of the highway departments of the sixty odd cities studied, indicate varied and detailed methods of control and organization. Generally speaking, their entire highway activities are centralized under one coordinating or directing head who is charged with full responsibility for administration, design, construction, maintenance and inspection. On the other hand, in some cities of the first rank, there is a division of authority and responsibility. In these, design and construction are under one chief and maintenance is under another, without a supervising and coordinating head over both. In this latter class of decentralized control is one of our larger cities, which has separate and independent boards; one controls construction and the other controls maintenance. The law under which the maintenance board operates prohibits maintenance repairs to more than 15 per cent of the street area. Consequently, if maintenance funds are not readily available the street is neglected until 15 per cent or more of its area is in need of repair. It then automatically becomes the burden of the board on new construction. As a consequence many streets with several years of life and which are worthy of economical repair are left to go to pieces until new construction can be undertaken.

Organization detail in cities must necessarily vary widely due to local laws and conditions. The work of construction and maintenance is so closely related that a division of authority cannot be economical or efficient regardless of the size of the city. While the resurfacing of an asphalt street by stripping the base or by the super heater method may be primarily called a maintenance operation, the construction division is usually better equipped to handle such operations. Many conditions could be cited to illustrate the desirability of and necessity for both branches reporting directly to a common active head.

Many cities while reporting the design and construction division as one, seemingly divide these functions. The peculiar operation of this division in the highway department of the District of Columbia may merit your consideration. The engineer in charge of the division of design and construction, in addition to his assistant construction engineer, is supported by nine assistant principal engineers, each in charge of a designated character of work. The assistant engineers are responsible for and execute the design of their own field work under the supervision of the assistant engineer of construction. They are responsible for design, field layout, co-ordination and general supervision. This organization has been found to operate satisfactorily by centralizing responsibility for results and progress.

Few cities attempt to maintain, as an independent unit of the highway department, an inspection division. Most cities, of any size, necessarily provide for inspectors in their organization but usually place them under the construction engineer in charge of the project. My study of this highly important phase of our work and organization has convinced me of the necessity in cities of sufficient size for an independent unit under a chief inspector who is responsible only to the bureau chief. Construction engineers, while interested in quality, are chiefly concerned with grades, progress and the like, while the inspector is or should be interested above all other things, in quality and compliance with the plans and specifications.

If a city on account of its size or the amount of work being performed annually cannot justify qualified annual inspectors, the employment of the services of an organized and qualified inspection bureau is necessary and justified. Without proper field control, inspection of materials, engineering and design goes for naught. Field control is the heart of your work, if it is inadequate failure is inevitable.

The organization charts of the highway activities of three cities are presented to show some of the variations in organization:

No. 1—A city of 200,000 population.
No. 2—A city of 500,000 population.
No. 3—A city of 1,100,000 population.

Method of Financing for New Pavements.—The usual procedure of financing for new pavements is through special assessment and bond issues. Local streets are financed by the assessment method and main arteries by bond issue, followed in some cases by partial assessment. Only in rare instances do cities report direct appropriation followed by assessment. This latter method is followed in the District of Columbia and reacts with great favor to the highway department, whose work for the season can thereby be well planned in advance. In new sections a great deal of paving is undertaken by private parties under the whole cost method; the work being performed under permits issued by the engineering department, which require that the work be carried out under current specifications and district inspection.

In the matter of special assessment for street improvements, in spite of its importance, very little study has been given to the subject; consequently there is little uniformity or standard procedure.

A study of assessment procedure based upon reports from twenty-six cities having each a population of 100,000 or more shows the following methods:

New Street Paving.—The method most used is the 100 per cent assessment of abutting property by the front foot. In some instances this method is not completely used as intersections and other exceptions are made. In ten cities paving costs including intersections are assessed. In eight, the paving, except intersections, is assessed. In two, the city pays for intersections plus 2 per cent of the remaining cost. In two, the assessment is to the extent of actual benefit and the remainder is paid by the city. In one, the abutting property is assessed for a 12ft. strip, the balance,

including intersections, is paid for by the city. In one, parkways and special traffic streets are paid for entirely by the city; on other streets the abutting property pays 100 per cent, less intersections. In two, assessment is based entirely upon character of street, varying from 20 per cent to 100 per cent.

Eighteen cities of those studied assess benefits on the front foot basis, one on the area basis, three use zones, and two a combination. In several cities, property on the intersecting streets for a part of the block, are assessed.

Washington's method is based upon the so-called Borland Amendment passed in 1914, which requires street paving to be assessed once only. Fifty per cent is assessed against the abutting property owners (25 per cent on each side) up to a width of 40 ft., less all intersections, and the balance, including intersections and widths in excess of 40 ft., is paid by the city.

Sidewalks.—In practically every city the entire cost of sidewalks is assessed against abutting property. In Cleveland and Philadelphia sidewalks are constructed and paid for by the property owner. In Washington 50 per cent of the entire cost is assessed (whole cost sidewalks are permitted when laid under district specifications and supervision).

Grading.—In fifteen of the cities studied, the cost of grading is assessed by the same method as paving, or included in the paving cost. In one, however, only sub-grading is included and general grading assessed against a benefit district. In ten cities, original grading is assessed either by assessment against abutting property or a benefit district created for the purpose. In two, one of which is Washington, there is no grading assessment.

Curb and Gutter.—In practically all cities the assessment for curb and gutter follows the paving assessment procedure.

Repaving.—Sixteen cities assess the same as for original pavements, however, some add special provisions as to age when replaced. Five cities make no assessment for repaving. In one, there is no assessment for repaving, if pavement is less than 15 years old. In one, cost of assessment is limited to $3 per yard. In Cleveland, the assessment is for 50 per cent of the cost. In one, two-thirds of the cost is assessed against abutting property. In one, one-half, and in one, one-fourth.

In Washington, pavement assessment can be made but once. Prior to 1914 there was no assessment. As the pavements so far replaced were laid before 1914, assessments are made as streets are repaved and at the same rate of assessment as for new pavements. If it is desirable to surface a street paved with concrete or block, and which had been previously assessed, the property cannot again be assessed. In the case of all street improvements, except paving of roadways, the law provides for advertisement for objection at a public hearing of abutting property owners. The board of commissioners determine after a hearing whether or not to overrule any objections and order the work to proceed in the interest of the public.

It appears that all cities use assessments in one form or another and that the usual manner of payment to the contractor for the work done is by one of two methods:

(1) By certificate of assessment, in which case the contractor assumes the responsibility for collection and suffers any loss of those that are uncollectable.

(2) By cash. The city obtaining the necessary funds partly from property owners, who pay when the work is completed, and partly from the sale of assessment bonds. Bonds are liens against the property, some cities guarantee them; some do not.

(Washington pays by cash appropriated directly by Congress. The cash funds are obtained from general taxes and the gasoline tax.)

The first method which is practiced in a great many cities where the 100 per cent assessment plan is used undoubtedly encourages and necessitates the contractor to increase his unit bid to cover anticipated losses.

The assessment for street improvement as applied to roadway paving was practiced years ago as a purely local benefit. When the laws were written undoubtedly such was the case, but today, except in the case of purely local residence streets, the extent of the local benefit is doubtful. Conditions, since the original assessment laws of most cities were passed, have materially changed. Roadways are designed and constructed today for general traffic requirements and only in a small part as local benefit. If our assessment laws are out of date, the time has arrived when a larger part of the pavement cost should be passed on to the user and the property owner relieved of some of his burden.

Contract Procedure.—Applying the term "contract procedure" to mean the method of letting contracts for street improvements, it is found that cities utilize the same general policy of letting a separate contract for each street whether the work is for one block or more. Several streets may be included in one letting but separate contracts made for each. This procedure is undoubtedly made necessary in many cases by law, but it involves enormous clerical and other work, judging by the number of contracts in each city during one year. In cities over 300,000 population, where considerable work is undertaken each year, the number of contracts for street improvements vary from 94 to 997. In cities with a population of 100,000 to 300,000, contracts vary in number from 21 to 180.

In Washington the system is so entirely different from other cities that it may merit your interest. Bids are invited at the start of the working season, usually in March, for each class of work. Projects are advertised in groups of sufficient size to constitute a season's work, except that a few minor contracts are made from time to time. Some of the contracts require completion by December 1 and some require a percentage of completion on that date. The balance of the contract being completed during the following spring by June 30, the end of the fiscal year. The exact dates are determined by our ability to pay and the size of the contract. The specifications are issued stipulat-

-ing the amount upon which bids will be scheduled. The statement is included that a list of streets from which work will be allotted the contractor is on file for his examination in the engineer of highway's office. The system has proven successful and has resulted in low bid prices as compared with those of several other cities. This method also insures continuous work during the working season and attracts contractors who have adequate organizations and equipment.

The qualification of bidders and contractors for executing important highway and street improvement in cities should receive the serious consideration of the sub-committee on contracts. The pre-qualification of bidders is practiced in some states while in others contractors are required to present satisfactory evidence of adequate experience, financial resources and equipment to execute the work successfully. Cities would do well to follow, in part at least, the requirements made by our states.

Selection of Types of Paving and Streets to be Paved.—The selection of the character of paving for various projects, certainly in all of the larger cities, is based almost entirely on traffic requirements. Generally speaking, the types, without reference to the design, have been generally standardized. Exceptions are the local or unimportant streets and the reclaiming of existing structures.

The procedure of selecting streets to be improved is similar. Cities follow practically the same course, namely, the improvement of main arteries and thoroughfares are selected by the board of improvement and the local streets are selected after reviewing requests and petitions of property owners and others.

Financing and Charges for Street Openings or Cuts.—The charges to public utility companies and others for repairing cuts or openings in improved streets are made on both the flat rate system and the cost plus system. Some cities use both. Washington, for example, is in the latter class and uses the flat rate based on published charges for replacing all existing types of paving and sidewalks when the area is less than 10 square yards. The cost plus system is used when the erea is in excess of 10 square yards. The percentage added where the cost plus system is used varies from 5 per cent to 15 per cent. Nearly all cities require a deposit in advance of permit. The whole subject of cuts, including replacement and repairs, is one in which all cities are vitally interested. I believe it merits the appointment of a special committee to study and report in detail on financing, charging, methods, repairing and inspection.

Cost Records.—Few cities keep or attempt to keep any detailed cost data. Some have records of labor and material, but only a few can give accurate cost data for various operations. Even those that attempt any system of accounting procedure are so vague as to details included in ascertaining the cost, that the reports are of little value. Cost data is essential and indispensable to the proper and efficient management of any municipal highway department. A uniform system of accounting would make comparisons possible, which would lead to more effective management and standardization of principles of operation.

In connection with keeping cost data as applied to roadway repairs it would be decidedly advantageous to have a corresponding record of area repairs, exclusive of cuts, for each type of paving.

In reviewing the subjects assigned this committee I have reached the conclusion that organization and selection of streets to be paved, are problems for the individual cities. Further detailed study will accomplish little but to furnish interesting data for comparison. The matter of assessment or financing for new pavements, contract procedure, financing and charges for cuts, and cost records, are in my judgment worthy of close study and investigation by subcommittees, one for each subject. An exhaustive investigation and study of the various practices followed by a report with specific recommendations will be of inestimable value to all city highway officials.

Pavement Design and Construction

Preliminary Report of Committee Presented Jan. 15 at Cleveland

By GEO. B. SOWERS

Chairman Design and Construction Committee; Deputy Commissioner of Engineering and Construction, City of Cleveland, O.

MANY millions of dollars are spent each year, by the cities of this country in the construction and maintenance of pavements, more money than is spent in any other one municipal enterprise. This tremendous expenditure is prompted and justified by the health and pleasure of the people and the economic demands of business. A city must provide and maintain a pavement in every street.

Much of the city paving work is still in an experimental stage. New designs, methods and materials are being adopted in different places without taking advantage of the experiences of other cities. Experience is expensive, and requires years of time to be acquired. No one city official has the time or facilities to gain personal experience on the service and merits of all the paving designs, or methods and materials which are available.

What better way is there for obtaining the accumulated experiences of many cities than through the work of the design and construction committee? Cannot our greatest service be through the accumulating and disseminating of the paving experience of cities? Factors of size of city; climate; kind of subgrade; the variety of machinery; the quantities and size of materials used, all offer most valuable fields of study.

The executive committee therefore thought it best to present a tentative outline of such a study as a basis for work during the coming year. There are no findings or conclusions in my report, but only suggestions which will be still further enlarged, I hope, by discussion. The executive committee has divided the tasks of the design and construction committee into seven major topics:

I. Contracts and Specifications.
II. Roadway Widths.
III. Subgrade.
IV. Pavement Bases.
V. Wearing Surfacing.
VI. Street Railway Tracks and Paving.
VII. Field Engineering and Inspection.

Let us take up each in turn and see what possibilities can be developed.

Contracts and Specifications.—First let us consider contracts and specifications because they offer an unlimited field for study.

I have found the standardization of specifications very interesting and profitable. Standardization and simplification of specifications will bring about the elimination of economic wastes, and permit the producers of paving materials to lower the selling price of their product through a reduction in manufacturing costs. They also allow the manufacturers of road building equipment to reduce the number of sizes of equipment, and thereby lower their costs. Standardization and simplification will therefore lower the final cost of the pavement to the public.

In the Cleveland metropolitan area there are a large number of independent municipalities. A few years ago it was realized that the same paving contractors and material dealers served all of the municipalities under many different specifications. At the instance of Mr. Hopkins, our regional vice-president and the city manager of Cleveland, the engineers representing the Cleveland metropolitan area met and adopted a uniform set of paving and materials specifications. These standardized specifications have proven to be very advantageous.

There are a great many national associations and boards working upon the standardization of paving materials. As the requirements for materials become standardized throughout the country, the combining of these ma-

terials into a pavement can be standardized.

Standard specifications advocated by an association such as ours, should be so prepared that each engineer can adapt them to his peculiar conditions.

Competition is an essential requirement in all specifications issued by municipalities. It is generally prescribed by law. How can paving specifications be written to use the new patented materials and processes, and at the same time permit competition?

The contract form and general provisions, as well as the more general part of the specifications are not well adapted to standardization. State laws, municipal ordinances, and local practices govern these features in each municipality.

Progress towards standardization will be slow and we must not expect too much this first year.

Roadway Widths.—Roadway widths are probably a function of city planning, but they generally are determined by the city engineer. If the street right-of-way is wide there is always the opportunity to use a liberal roadway width. Many of our street rights-of-way were fixed before the era of motors, and the paving engineer is limited to the width of the roadway that he can crowd into the existing right-of-way and still leave room for a sidewalk of reasonable width, together with a space for poles and fire hydrants.

In a city such as Washington, the roadway widths may be made more generous in order to carry out the picture of spaciousness, but in cities such as Philadelphia, where land is very valuable, the right-of-way is made the narrowest permissible, and the paving engineer must plan the pavement width with the greatest care.

On inter-city highways the general rule for fixing the roadway which seems to be 10 ft. of pavement for each line of moving vehicles, and 8 ft. for each line of parked vehicles. Does this same rule apply to the main traveled business streets of our cities where traffic naturally moves more slowly, or can a narrower width of lane be used with safety?

The width of traffic lanes around curves should perhaps be given study. The theoretical additional width required for a turning vehicle can easily be determined, but the proper allowance that should be made for the inability of drivers to keep within the curved lines of a traffic lane apparently has never been determined.

Subgrade.—The subgrade is one of the most popular paving subjects today. The study of soils in pavement subgrades is intensely interesting because of the great variety of soils and the many possibilities for improving the unsuitable ones. Subgrade soils range from the most perfect sand soils to the worst clay, silt or muck.

Each unsuitable type of soil requires a different treatment to meet different kinds of climatic and pavement conditions. As yet no certain rules have been found which will apply in every case. Much work has been done in the United States Department of Public Roads and the results of some of their studies will soon be published. Wonderful progress in soil investigation is being made in some of the state highway departments, but little study has been given to the subgrades in cities.

Instead of continuing to build thicker and stronger pavement bases in an effort to carry the increasing traffic loads over more or less unstable subgrades, it is more logical and economical to increase the supporting power of the subgrade. No economical thickness, or strength, of plain concrete will carry the loads of traffic over a subgrade which becomes unstable under certain climatic conditions. The only reasonable solution of this problem is the increasing of the supporting power of the subgrade.

The subgrade material in the City of Cleveland ranges from perfect sand to clays that heave and lose almost all of their supporting power at certain times in the year. In the clay areas of Cleveland the supporting power of the subgrade is being economically increased through the use of a 4-in. cushion blanket course of granulated slag under the concrete base, with plenty of drains to take the water from the porous layer. The past year has been the third season that this porous sub-base has been used. It has overcome considerable cracking of the surface and the pavements are carrying the maximum loads without failure.

The granulated-slag cushion blanket course has a tendency to cement together, forming not only a porous insulating layer, but also adding greatly to the strength of the pavement foundation.

The compacting of the subgrade prior to paving is another of the subgrade problems. Should not the soil under a pavement be left or placed in its natural condition, if it is to provide a uniform bearing for the pavement? If over compact, it will expand to its natural condition in the course of time and raise the pavement, and if undercompacted, it will gradually consolidate and settle away from the pavement foundation.

Some engineers believe that the subgrade should be rolled with a 15-ton roller, while others require only a 5-ton roller. The heaver roller finds all the soft spots and uncompacted trenches in the subgrade, but it may over compact compressible subgrades in spots. The result is that the subgrade material expands to its natural condition in the course of time, causing unequal support under the pavement foundation.

It frequently happens after the subgrade is fully prepared to receive the pavement that it is cut to pieces by the trucks hauling the concrete aggregate or the mixed concrete. This damage has been overcome in Cleveland by the requirement that no trucking shall be allowed directly upon the subgrade or cushion blanket course. Trucking is permitted only upon a plank roadway or equally effective method for distributing the load.

Pavement Bases.—Pavement bases cover a large field for study. The thickness of the concrete base for various kinds of surfaces and assumed load conditions is worthy of considerable study.

Many engineers believe that a concrete having a 2,000-lb. crushing strength is the most economical for pavement bases; others claim that cement should be added to produce a concrete having a 3,000 or 4,000-lb. crushing strength. If it is only a question of additional density or of waterproofing, the same results might be obtained through a waterproofing of the concrete, instead of using a mixture which is richer in cement and which therefore expands and contracts to a greater extent.

A 4-in. Granulated Slag Cushion Blanket Course on East Boulevard, Cleveland

The city of Cleveland's specifications produce a concrete having a crushing strength of between 2,500 and 4,500 lb. per square inch at 28 days. This is probably 1,500 lb. higher than was used 10 years ago. There is some question as to whether or not the resulting increased coefficient of expansion is the cause of many of the broken places in the pavements.

In some parts of the country, macadam pavements have been used quite extensively in city streets. The old macadam pavements have been resurfaced with bituminous mixtures and the resulting surfaces in many cases are highly satisfactory. There is no doubt a field for the use of macadam bases under bituminous wearing surfaces, but all the facts are not known.

Some study should also be given to the use of such foundations as black base, and the natural sand bases.

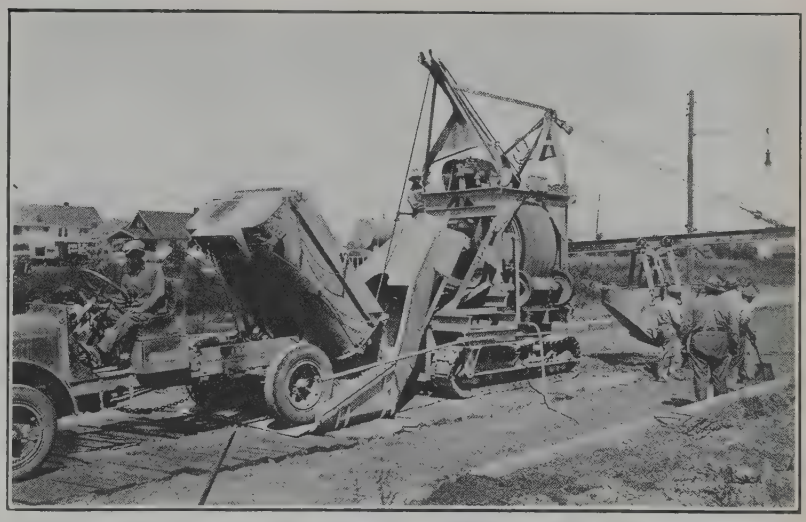
The Highway Research Board found that wire mesh reinforcement is advantageous in concrete roads because it reduced the width of cracks. Wire mesh reinforcement would probably be of value in pavement foundations. The city officials' division will make a comprehensive investigation of the question of pavement foundations, including the use of wire mesh reinforcement. Mr. Hogentogler of the Bureau of Public Roads, who conducted the survey on the use of reinforcement in concrete pavements, has consented to undertake the study of pavement bases. He is prepared to give a large amount of his time to this investigation.

The drilling of cores from pavement bases is a comparatively recent development. There is still much to be learned. Many city engineers do not believe that it is necessary, but Cleveland has found that it results in better and more uniform concrete foundations, both in thickness and strength.

Individually the cores drilled from pavement bases prove nothing, but collectively they give a good indication of what might be found if the entire base could be taken up, measured and tested. It is true that one little core taken from a length of pavement is a very small part of the whole, but obviously it is impracticable to examine the entire pavement base.

I believe that this committee can render a valuable service to the city engineers through the working out of a standard method for checking and testing the strength of concrete bases. All engineers desire uniform thickness and strength of the concrete, but they have not developed satisfactory methods for checking these items. Cores drilled from the pavements greatly assist in the solution of these problems.

The proportioning and grading of the concrete mixture and the consistency and workability of the concrete can all be more easily controlled at a central mixing plant. The resulting concrete has a more uniform final strength. There is also the possibility that the transporting of the concrete results in the elimination of air entrained in the concrete. This fact may account for some of the additional strength shown by the ready-mixed concrete. Warm concrete for use in cold weather construction is accomplished more easily with ready-mixed concrete than with concrete mixed on the street. Specifications should be developed to permit and control its use.



Planking on Subgrade on West Avenue, Cleveland

Many of the methods adapted to the curing of concrete roads in rural sections cannot be used in city streets. Ponding, earth covering or straw covering are some of the methods not practical in cities for obvious reasons. Sprinkling with water is probably the most common method used. Sodium silicate, asphalt spray and calcium chloride are being tried. Data and specifications for the use of the various curing methods would be welcomed by the city engineers I am sure.

Wearing Surface.—The wearing surface of pavements offers another unlimited field for study. The Bureau of Public Roads has found that the function of the top layer or wearing surface is to take the wear and absorb a portion of the impact from moving loads. Smoothness without slipperiness is one of the essential qualities of a wearing surface.

Time is an important factor in the paving of most city streets. Wearing surfaces which can be laid and opened to use in the shortest possible time have decided advantages. The minute a pavement is completed the public demands that it be turned over to them for use. The closing of one block in a built-up city means congestion in all adjoining streets, with a subsequent loss of business, and an increase of traffic and fire hazards.

The increase in the use of asphalt as a filler for block pavement surfaces has brought the problem of how to keep the asphalt from forming an unsightly and rough surface on the pavement during the first year after it is laid. Some asphalt fillers also become very sticky during warm weather. There are also asphalt fillers which become brittle and pull away from the blocks when the surface contracts, thereby defeating one purpose of an asphalt filler, namely, that of flexibility.

A non-skidding surface is one of the most desirable features of a pavement. Stone, vertical-fibre brick and some bituminous concretes present excellent non-skid surface. A cold-laid asphaltic mixture is being tried in the Cleveland area on hills having as high as 6 per cent grades.

The low annual cost and the ease with which it can be opened and replaced makes the sheet asphalt pavement surface very desirable for use on wide, heavily-traveled city streets.

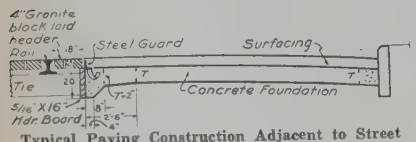
The plain and reinforced concrete pavements have proven very economical on rural highways. The use of concrete as a city pavement has not been as well developed. The finishing machines which have been so successfully used on rural highways have not been perfected for all classes of street paving, with the result that much of the finishing must be done by hand with consequent unevenness and over or under compacting and finishing. Study by your committee could do much to perfect the design and construction methods for concrete pavements.

Brick or stone-block gutters are used in many cities in combination with asphalt surfaces. There is some question as to whether these gutters are necessary or justified from the standpoint of cost. Some engineers claim that it is cheaper to use brick or stone gutters than to replace disintegrated asphalt gutters with new asphalt.

Street castings, manhole tops, valve boxes and catch basins are pavement details which require study and stand-

ardization. The improper setting of these castings results in holes and bumps, too many of these castings are designed solely from the standpoint of the public utility with no consideration given to the paving. We are very careful to obtain a smooth pavement surface, yet many city pavements are filled with street castings, each making a bump which is as undesirable as a hole in the pavement surface. The breaking of manhole and catchbasin tops is a continual source of damage claims in cities having heavy concentrated loads passing over the streets. Considerable study could well be given to the standardizing of street castings, their design and construction.

Street Railway Tracks and Paving.— The paving of the street railway tracks is closely allied to the construction of



Typical Paving Construction Adjacent to Street Railway Tracks, Cleveland

the tracks. Studies of track construction are being carried on by the American Railway Association. It is possible that the work of this division can be coordinated with the study being made by the railway companies themselves.

Considerable difficulty has been experienced in maintaining the roadway pavement outside the track area because of the vibrating and moving of the track construction. The edge of the pavement adjacent to the street railway track probably receives the heaviest traffic of the entire roadway. To compensate for the lower strength of the edge of the concrete pavement base, it has been found desirable, in Cleveland, to thicken the edge of the roadway slab adjacent to the track construction. It has also been found desirable to make a complete separation between the roadway pavement and the track construction, in order that the renewal and repairing of the track might not undermine the edge of the pavement or cause the paving surface to unravel. The present paving construction of the City of Cleveland now provides that a concrete beam shall be cast integral with the pavement base adjacent to the ends of the ties. The beam extends below the subgrade of the track pavement. The pavement surface is supported by a metal curb, which is built into the concrete base.

A number of materials have been used for pavement surfaces within the street railway tracks in Cleveland. The greater portion of the recent construction has been grout-filled granite blocks. Where the railway tracks are new and solid asphalt has proved satisfactory. Some concrete and brick paving has also been used.

Field Engineering and Inspection.— Finally, unless the field engineering and inspection follows a uniform interpretation of the standard specifications, the purpose of standards is only partially accomplished. Much good could be secured through the preparation of a standard manual of instructions and interpretations for the use of field engineers and inspectors.

The City of Cleveland has a manual of instructions for the use of its district engineers and inspectors. The city's contractors are assured of uniform engineering and inspection requirements whether their work is in one part of the city or another.

The form of the field organization in any city is largely determined by legal requirements and by precedent. Changes in the form of the organization can be made but slowly. It would probably be of value to city officials if they knew more about the form of field organizations in other cities. Such data could be collected and prepared in tabular form by your committee.

The use of full time, all-year-around inspectors, is very desirable from the standpoint of paving construction, but it brings the greater problem of how to pay and where to use this large group of men during the winter season. Perhaps some other city has solved this problem and your committee can learn of the solution.

Street Maintenance Committee Report

Committee Report Presented Jan. 15 at Cleveland Convention

By MAJOR C. E. MYERS
Chairman Committee on Maintenance; Director of Transit, Philadelphia, Pa.

IT is contemplated at this time to divide the maintenance committee into eight sub-committees, as follows:

1. Pavement Bases.
2. Concrete Surfaces.
3. Bituminous Surfaces.
4. All Types of Block Pavements.
5. Street Openings or Cuts.
6. Street Cleaning.
7. Resurfacing and Salvaging of Existing Pavements.
8. Unpaved Streets.

This first report of the general maintenance committee plans to touch briefly on the proposed work of each of the subcommittees. It does not contemplate making recommendations, but plans simply to state briefly the present status of the various kinds of work and the normal methods of procedure now in vogue in various cities. When it is realized that nearly twenty-five and a half million dollars is spent annually on maintenance alone, and largely by forces employed directly by the City, in some three hundred and twenty-six cities that have been tabulated, the importance of this subject may be grasped.

The work of a maintenance committee differs somewhat from a construction engineer's work. The maintenance end of the proposition does not advocate changes of types of paving, but must take what it finds, having inherited all kinds and all types of bases and surfaces. Its problem is to present a method of making repairs to its inheritance, whether or not the committee enjoys or believes in what it has inherited.

Pavement Bases. — Maintenance of pavement bases consists in most cities of making repairs to existing concrete bases. There are, of course, some old broken stone bases and some bituminous bases, but the larger quantity of the present street bases throughout the country appears to be concrete. Rigid type bases are found to exist varying from 5 in. of a 1:3:6 mixture up to extreme cases of 10 in. of a 1:2:4 mixture.

Repairs, generally, are made by maintenance forces directly in the employ of the municipality. Some cities have portable units, and make the repairs and mix the concrete on the street; other cities use pre-mixed concrete or wet batches for maintenance repairs. Some cities use an admixture in their concrete in order to close their openings as quickly as possible; others use a foreign fast-hardening cement and some an American fast-hardening cement; still others use a richer mixture for their repair work than was in the original base. There seems to be no uniformity in this field, each municipality being more or less of a law unto itself.

Concrete Surfaces.—As far as municipal work is concerned, with the exception of Seattle, Wash., and Washington, D. C., very few cities have adopted a concrete surface for city pavement work, owing, in general, to the difficulty in making repairs. The city of Washington, which probably has the largest yardage of concrete surface pavement to maintain, repairs entirely by city forces. They operate a concrete repair gang which is organized as a mobile unit and mix their concrete at or near the point of deposit. They maintain another gang exclusively for the pouring and sealing of cranks and joints. Throughout the country the general method is to make the repair of the same material and the same mixture as the original surface.

Bituminous Surfaces.—Repair work to bituminous surfaces, which, in the case of most cities, means sheet asphalt pavements, is taken care of almost universally in the larger cities by municipally-owned asphalt plants, and the material is laid by city employees. There are, of course, some exceptions to this rule. Some cities have annual contracts for asphalt repairs. The contractor is required to make the repairs not to exceed a total annual established yardage when and where desig-

nated by the engineer. Some cities also use small portable units for making their repairs.

Repairs to other types of bituminous surfaces are made in general with two types of material commonly known as "hot mix" or "cold mix." Under each of which sub-divisions there are a number of established methods.

Bituminous surface treatments are usual practice on the various macadam types of paving which are found in the outlying sections of the smaller cities, and sometimes very generally throughout the smaller cities. Again there are two general types of treatment—the hot and the cold application.

All Types of Block Pavements.—The general types of block pavements are wood block, asphalt block, vitrified block and stone (including granite) block.

Wood block has found but very little favor in city paving work in the past few years, and is rapidly being replaced with other types, quite frequently by the city maintenance forces. It is a very difficult pavement to maintain, as it is difficult to replace a small area because of the uneven wearing of the wood block.

Asphalt block has, in general, been unsuccessful, except in certain locations on wide streets where the traffic is well distributed. Like wood block, this material is very difficult to maintain because of the replacement. In many cases it is being replaced by another type of surfacing, usually by sheet asphalt. Asphalt block, however, is a convenient type to maintain in the small town that is not equipped with an asphalt plant.

Vitrified block at one time was used, especially in the smaller cities, almost exclusively, then fell into disfavor owing, generally, to inadequate bases. It is now rapidly returning to its proper field supported by an adequate foundation. It is a very easy type of pavement to maintain. Work can be handled with small gangs and small areas adequately patched. The older types are found with a sand filler; the more recent ones with a portland cement grout filler; and the very latest almost exclusively with a bituminous mastic filler.

Granite block has been and always will be the most nearly perfect surface for heavy traffic streets, especially on narrow width streets which are subject to tracking or rutting. Its expense, however, prevents quite frequently its use where conditions really warrant it. Its maintenance is very easy and simple, and replacements can be made in small areas, which is a distinct advantage. Like vitrified block, it is found in older cases on a sand foundation with a sand filler. The more modern pavements are either portland cement grout or bituminous mastic filler.

Street Openings or Cuts.—This is probably the most annoying of all maintenance problems. The practices in general use necessitate securing a permit to make the opening and replacement of the pavement in kind, i. e., the replacement to be made of the same material as the pavement removed. The method of making cuts and restoring them varies widely. Some cities require the company wishing to make the cut to take out a permit for each opening, to pay a fee to the city for the permit, and to make the replacement under city supervision. Other cities permit a company to have a blanket annual authority for making openings where they will, and to pay the city for the number of openings made in a calendar year, the company to replace the pavement. Still other cities permit a utility company to make the cut, charge them a fee for the permit and for the restoration, and then have the restoration made either by city forces or by an annual city contract. The committee believes that this subject should be one of those brought out at an open meeting discussion, and some effort made to secure uniform practice throughout the country.

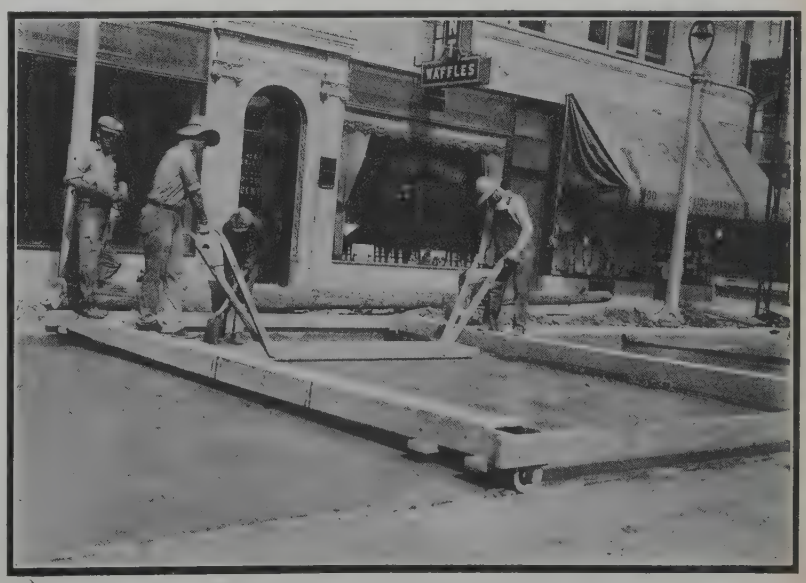
Street Cleaning.—The subject of street cleaning comes, from an organization standpoint, in some cities under the same head as highways; in others it is a separate bureau or department and has no connection with the highway organization. The street cleaning work sometimes consists of the flushing and cleaning of streets, the cleaning of inlets, the removal of garbage and waste, including ashes and sometimes one or more of these functions are done by other bureaus. Snow removal is handled, in some cities, by the street cleaning department, and in some by the highway department; other cities unite both departments and clean snow as an emergency measure.

For the normal cleaning of streets, the larger cities nearly all use power equipment for cleaning and flushing, supplemented in many cases by hand sweeping. Some cities use a vacuum or horse drawn brooms followed up by hand sweeping.

Snow cleaning and snow removal are handled in many ways by different cities. Some use snow blades mounted on trucks and simply plow the snow to the sides or center of the street; other cities use power loaders and remove the snow from certain streets; other cities do certain snow removal by hand. This is a very large subject, and it is hoped that this division will see fit to give it a great deal of study.

Resurfacing and Salvaging Existing Pavements.—This is a most interesting subject and one upon which much future discussion will be profitable. In many cases the resurfacing or salvaging is almost as expensive as complete repaving unless the base condition is completely ignored, and if this is done the salvaging is usually of little value. There are many cases where old block or brick pavements which are worn down can be crowned up to a true cross section, and by the use of surface heaters asphalt or other bituminous mixture may be applied to them. This same surface treating method may be used on portland cement concrete pavements, and many engineers believe that the ultimate end of the existing portland cement concrete roads is to cover them with a bituminous top.

Unpaved Streets.—The question of unpaved streets is one that varies in each locality. In many sections where there is a hard gravel natural soil, very little attention is paid to a street that has been graded and not paved until such time as buildings are erected on the abutting property. There are other cities, however, where street paving may have been omitted in one or two blocks on a street that is a very



important thoroughfare, and because of the assessment system in vogue the property owners on the abutting property, not having developed it, object to the paving charge. The result is that in most large cities there are certain sections of unpaved streets which are subject to an undue amount of traffic and must be kept in fair condition by the maintenance forces. This usually consists of taking care of the drainage as well as possible, and doing such crowning, including road dragging, as is practicable.

In many cases earth roads are given a dust laying oil treatment; in other cities they are sprinkled with water; while in still others, a bituminous application is made and chips are placed and rolled to give an inexpensive surface which is satisfactory for light traffic, at least in warm, dry weather.

In conclusion, it is believed that the eight sub-committees should be appointed and their work laid out for them at an early date, in order that at the next annual meeting a complete report may be made by each of the sub-committees. There seems to be throughout the country a wide difference of opinion as to the best methods to be employed in maintenance work, and it is believed an effort should be made to standardize the maintenance work of the various cities and that next year the maintenance committee should make recommendations along this line.

The work of sub-committee No. 5, Street Openings or Cuts, and of sub-committee No. 7, Resurfacing and Salvaging of Existing Pavements, covers, we think, two of the most important subjects in the highway field today.

Traffic on City Streets

Committee Report Presented Jan. 15 at Cleveland Convention

By M. O. ELDRIDGE
Chairman Committee on Traffic; Assistant Traffic Director, Washington, D. C.

THE City Officials' Division of the American Road Builders' Association, when organized in Washington on June 8, 1928, decided that one of its four major committees should deal with the question of traffic.

The object of the association in creating this committee was to collect and disseminate useful information, regarding traffic problems and to cooperate with other organizations in bringing about a reduction in the appalling loss of life, personal injury and property damage, and to facilitate the movement of traffic on the nation's streets and highways.

The traffic committee has not yet been organized, but a tentative schedule of assignments for committee work has been proposed as follows:

1—Causes of Accidents.
2—Rules of the Road.
3—Traffic Light Signals and Signs.
4—Parking Regulations.
5—Weights and Loads.
6—Traffic Zoning and Classification.
7—Drivers' Permits.
8—Safety Equipment.
9—Street Lighting.
10—Traffic Law Enforcement.

A letter was sent to each member of the city officials' division, who had indicated his willingness to serve on the traffic committee, requesting suggestions based on observations and experience on any one or all of the subjects selected for committee assignment. This was done in order that a preliminary report might be prepared and presented at the annual meeting of the association.

Sub-committee chairmen will be selected as soon as possible and assigned to the task of finding out how cities are going to take care of their future traffic problems and at the same time bring about a reduction in traffic fatalities and accidents.

Uniform Motor Vehicle Laws.—It is believed that the association should at this time approve and support the National Conference on Street and Highway Safety in its effort to bring about the enactment of uniform motor vehicle laws in the various states and uniform municipal ordinances in the various cities.

After two years' work by nearly a thousand representatives from every state in the Union, composed of traffic specialists, engineers and experts, and including official delegates appointed by the governors of forty-three states, a uniform motor vehicle code known as the "Hoover" Code was adopted in 1926.

This code, consisting of four separate acts, has been approved by the National Conference of Commissioners on Uniform State Laws and by the American Bar Association.

These proposed acts are—first, a motor vehicle registration act; second, a motor vehicle anti-theft act; third, an operators' and chauffeurs' license act; and, fourth, an act relating to the rules of the road and the operation of motor vehicles.

Municipal Traffic Ordinance.—Owing to the fact that there is less uniformity in traffic regulations of cities than in state laws the National Conference on Street and Highway Safety was requested to supplement its previous work by the preparation of a municipal traffic ordinance which might be used as a model for cities. Accordingly the Uniform Vehicle Code has been supplemented by a model Municipal Traffic Ordinance which was adopted by the Conference in August, 1928.

The Uniform Vehicle Code includes all the provisions ordinarily contained in the state laws, such as the basic regulations relating to speed limits, reckless driving, rules of the road, safety equipment of vehicles, licensing of drivers, suspension and revocation of operators' permits, registration of vehicles and anti-theft provisions.

The model ordinance sets up a uniform procedure in regard to the direction and control of city traffic, the erection of directional and warning signs, signals and markers, the parking of vehicles, and rules of the road for the protection and regulation of both pedestrian and vehicular traffic peculiar to city streets.

The proposals made in both of these codes are based on the wide experience and good judgment of the best known traffic specialists, engineers and experts in the United States.

This work was recently supplemented by a valuable contribution made by the American Engineering Council for the National Conference on Street and Highway Safety suggesting standard practices, relating to street traffic signs, signals, markings and traffic control devices.

The Traffic Committee will endeavor to place in the hands of those members who are interested in traffic, a copy of the three reports above referred to, and, it is urgently requested that they use their influence to bring the adoption of these model laws and regulations in their respective states and cities. This is particularly important just now at some forty-three legislatures meet early this year.

Need for Traffic Surveys.—No city can expect to make any real progress in reducing accidents or in solving its intricate traffic problems until it is in position to make careful and continuous engineering surveys as to the quantity and quality of its traffic, and until it is able to say to some degree of certainty where, when, how and why accidents occur.

To this end it is recommended that every city in which the traffic problem has become acute, and that means practically every large city, should establish an engineering traffic department or bureau. The municipal traffic ordinance contains in an appendix a suggested form of municipal enactment creating such a traffic engineering department.

Such department should be equipped with adequate funds and trained personnel for making traffic surveys, flow maps and spot maps and for tabulating and analyzing traffic accident reports. Such surveys and studies will indicate among other things:

1—Where traffic lights should be erected.

2—Which streets should be designated as through streets.

3—Where "Stop" signs should be placed.

4—Which streets should be well lighted at night.

5—Which streets should be designated for one-way traffic.

6—Where, in the interest of safety or for increasing street capacity parking should be restricted or eliminated.

7—Those streets which should be

paved, widened or zoned for special classes of traffic.

Improvement in Traffic Conditions at Washington, D. C.—Many of the proposals made by the National Conference of Street and Highway Safety have been adopted in Washington, D. C. Additional features of the code will be adopted as soon as Congress can be induced to so amend the traffic act. The proposals already adopted have resulted in bringing about an improvement in traffic conditions.

This improvement has been brought about by—

1—Electric traffic signal lights along the lines suggested by the American Engineering Council.

2—The establishment of a system of through streets and the prohibition of parking on the flow side of such streets during the rush hour.

3—By the installation of a practical and effective program providing for the licensing of all motor vehicle drivers after an examination on the regulations and a driver's test.

4—By the prompt cancellation or suspension of the drivers' permits of those who have committed serious traffic offenses or who are found to be mentally or physically incapable of safely operating an automobile.

5—By a vigorous and impartial enforcement of the traffic laws and regulations.

That the traffic reforms adopted in the nation's capital are accomplishing the desired results is shown by the fact that fewer persons in each 100,000 of population have lost their lives in traffic accidents in Washington during the past three years than in any other metropolitan city in the United States.

In all fairness it must be said, however, that during the past year the traffic fatality record of one large city, namely, Baltimore, has shown an improvement over that of Washington.

In conclusion let me emphasize the thought previously expressed in this report and that is, that no city can expect to make any material improvement in its traffic accident problem until it is able to say with some degree of certainty where accidents occur, how they occur and why they occur.

City officials should always remember that accidents do not happen—they are caused. It is, therefore, recommended that this thought be adopted as the slogan of this committee—

"ACCIDENTS DO NOT HAPPEN—THEY ARE CAUSED."

Typhoid in the United States.—According to Public Health Reports for Sept. 7, 1928, the number of typhoid fever cases was unusually small during the past summer. The total for the eight weeks from July 1 to Aug. 25 was 5,821 as compared with 7,600 for the corresponding weeks in 1927 and 8,527 in 1926.

Bibliography on Regional Government

A Bibliography on Regional Government has recently been prepared under the auspices of the School of Applied Social Sciences and the Political Science Department of Western Reserve University.

Considerable time has been spent in making the Bibliography as complete and specific as possible. It contains 58 pages and references to about 645 specific sources, together with an outline and index with page references.

Part I includes articles and books of a general nature, while Part II refers to the various forms such as Special Districts, Annexations, City-County Consolidation, Borough Government and Metropolitan Areas. Parts III and IV contain references to County and Township Government. Part V includes articles on the Legal Aspects of this problem. Part VI deals with current bibliography. There are references to English and German articles as well as American.

This Bibliography has been carefully mimeographed and bound ready for distribution. Copies may be purchased at 50 ct. each on application to Roland Mulhauser, Library of Research in the Social Sciences, Western Reserve University.

Westchester County, N. Y., to Spend $1,545,000 for Park Maintenance.—The Westchester County Park Committee White Plains, N. Y., has notified the County Board of Supervisors that its 1929 budget would call for about $1,545,000 to operate and maintain the park system, including the general offices at Bronxville and "Playland," the newly opened amusement park operated by the commission at Rye Beach. This is an increase over the 1928 appropriation of approximately $343,000, but is due to more park facilities.

Indiana Water Works Men Meet in February.—The next meeting of the Indiana Section of the American Water Works Association will be held Feb. 27-28 at Indianapolis, Ind. C. K. Calvert, 1902 North New Jersey St., Indianapolis, Ind., is secretary.

Water Wasted by Various Size Orifices

The 40th annual report (1927) of the Board of Water Commissioners of Dover, N. H., contains the following interesting table showing the amount of water wasted through different sized openings. The table is calculated for a rate of 23 ct. per 100 cu. ft:

Cost of Water Wasted by Various Sized Openings

Diameter of orifice in fraction of an inch	POUNDS PRESSURE PER SQUARE IN. AT ORIFICE 50 lb. Cubic feet discharged per day	50 lb. Value at 23c per 100 cu. ft.	65 lb. Cubic feet discharged per day	65 lb. Value at 23c per 100 cu. ft.	85 lb. Cubic feet discharged per day	85 lb. Value at 23c per 100 cu. ft.
1-16	153	$ .35	167	$ .38	198	$ .45
1-8	613	1.31	667	1.53	760	1.74
1-4	2,467	5.77	2,667	6.13	3,066	7.05
3-4	21,333	49.07	24,400	56.12	28,000	64.40
1	39,466	90.87	42,667	98.12	49,066	112.85
1-2	9,867	22.79	10,667	24.53	12,266	28.21

The Troubles of the City Clerk

The following quip comes to us on the back of the business card of Mr. Arthur W. Smith, City Clerk, Amsterdam, N. Y.:

Pity the City Clerk

If the City Clerk writes a letter, it is too long.
If he sends a postal, it's too short.
If he sends out a notice, he's a spendthrift.
If he doesn't send out a notice, he's lazy.
If he attends a committee meeting, he is butting in.
If he stays away, he is a shirker.
If he sends out bills, he is insulting.
If he fails to collect bills, he is slipping.
If he asks for advice, he is incompetent; if he does not he is bull-headed.
If he writes his reports complete, they are too long, and if he condenses them, they are incomplete.
If he talks on a subject, he is trying to run things, and if he remains quiet, he has lost interest in the city.

Ashes to ashes,
Dust to dust,
If the others won't do it,
The City Clerk must.

Sewer Cleaning at Chicago.—During 1927 the Bureau of Sewers of Chicago cleaned 9,685,000 ft. of sewers by flushing, and 892,200 ft. by scraping. In addition 28,860 catch basins were cleaned by machine and 48,665 basins by hand. The cost of the work, according to the annual report of Geo. E. McGrath, Superintendent of Sewers, was as follows:

Flushing, per 1,000 lin. ft.	$ 7.58
Scraping, per 100 lin. ft.	13.67
Catch basin cleaning by hand	3.93
Catch basin cleaning by machine	2.63

Rocky Mountain Water Works to Meet.—The 3rd annual meeting of the Rocky Mountain Section of the American Water Works Association will be held Feb. 14 and 15 at Denver, Colo. D. E. Kepner, Division of Sanitary Engineering, State Board of Health, Denver, Colo., is secretary.

Eight Million Dollars Voted for Airports.—Bond issues for the purpose of purchase or development of municipal airports were voted at the November election by Detroit, Columbus, St. Paul, Seattle, Hartford, Chattanooga and five other cities aggregating almost $8,000,000. Detroit alone voted a bond issue of $5,000,000.

Annual Convention of Montana Water Works Men.—The 4th annual convention of the Montana Section of the American Water Works Association will be held April 4, 5 and 6 at Great Falls, Mont. H. B. Foote, Division of Water and Sewage, State Board of Health, Helena, Mont., is secretary.

The Water Filtration Plant of the City of Montreal, Quebec

Construction and Operation Features of New Extension

By F. E. FIELD and J. H. HARRINGTON
Filtration Engineer, Montreal Water Board; and Chemist Montreal Filtration Works

THE plant as originally designed by Messrs. Hering and Fuller and constructed under their supervision included the following:

Low lift pumping station, capacity 150 m.g.d. (Imp.).

Sixteen pre-filters, nominal combined capacity, 50 m.g.d. (Imp.), unit sand area, 1,200 sq. ft.

Sixteen final filters, nominal combined capacity, 50 m.g.d. (Imp.), unit sand area, ⅝ acre.

Filtered water basin No. 1, capacity 6¼ m.g. (Imp.); and such conduits, gate houses and equipment to make the installation complete and ready for operation.

Construction work was started in 1911, but on account of numerous delays was not completed and placed in service until April, 1918.

The cost of this plant complete, exclusive of land, was $1,408,300, or $28,000 per m.g.d. (Imp.) at normal rating.

The original scheme was to have the pre-filters and final filters operated together as one plant, i. e., double filtration, without the use of coagulant, but the conduits and gatehouses were designed to permit of the pre-filters and final filters being operated as separate plants or as partially combined plants.

This foresight on the part of the designers of the original plant has been amply justified.

In 1910 the average daily output of the municipal water works plant was 38 m.g. and the filter plant was designed for 50 m.g.d. nominal capacity which would permit of a 30 per cent increased output.

In 1918, the first year of operation, the required output of filtered water was 60 m.g.d. (Imp.) or 20 per cent above the designed nominal capacity of the plant.

The demands for filtered water increased rapidly in succeeding years and last year, i. e., 1927, the daily output was 85 m.g. (Imp.) or 70 per cent in excess of the designed nominal capacity of the plant.

During July, 1928, the average daily output was 92 m.g. and the maximum day's output was 97.6 m.g. or 94 per cent in excess of the designed nominal capacity of the plant.

Notwithstanding this excessive overload on the filters, the plant has run continuously and has at all times delivered to the citizens of Montreal a water satisfactory in all respects.

Filter Extension.—The need for additional filters has been recognized for several years, but construction was delayed until adequate pumping capacity was provided by the completion of the new low level pumping station.

This contains six 30 m.g.d. pumping units with provision for extending the building to house six additional pumps of the same capacity.

To provide ample storage of filtered water, filtered water basin No. 2 was constructed between filtered water basin No. 1 and the new low level pumping station. This basin, having a capacity of 20 m.g. (Imp.), was constructed at a cost of $624,400.

During the construction of the new low level pumping station and filtered water basin No. 2, several schemes for filter extension were studied and estimates of cost compared. The satisfactory operation of the existing pre-filters and the comparatively low cost of constructing 32 additional filters, similar in size, arrangement and general design, above the roof of filtered water basin No. 1 resulted in this plan being adopted.

These 32 additional filters will have a combined nominal capacity of 100 m.g.d. (Imp.) which added to the original plant will make the total nominal capacity of the plant 150 m.g.d. (Imp.), which equals the nominal capacity of the new low level pumping station.

In all probability the original 16 pre-filters and 16 final filters will be operated as a combined plant and the 32 new filters will be operated as rapid sand filters and discharge independently into filtered water basin No. 2.

The cost of this work now nearing completion may be subdivided as follows:

Earthwork, filters, buildings, etc.	$ 360,000
C. I. piping, gate valves and sluice gates	213,958
Air piping and small piping	17,880
Filter rate controllers	40,000
Filter operating tables and gages	66,641
Filter strainer and air system	67,867
Wash water gutters	17,203
Filter sand and gravel	69,038
Gages, telephone system and signal system	12,129
Chlorination building and equipment	24,000
Park lighting system	14,303
Fence and gateways	46,000
Greenhouse, trees and shrubs	11,500
Miscellaneous work and equipment	48,621
Total	$1,009,140

This makes the cost of the filter extension $10,000 per m.g.d. (Imp.) nominal designed output.

The total cost of the filtration works is therefore $2,417,440, which on the nominal designed capacity, 150 m.g.d. (Imp.), makes the construction cost $16,116 per m.g.d.

Filter Strainer and Air System.—The strainer system in the original pre-filters and the new rapid sand filters are identical and furnished by the Roberts Filter Mfg. Co. It consists of C. I. manifolds and 1¾-in. C. I. pipe laterals on 6-in. center, approximately 6 ft. in length with two ⅛ bronze orifices for each 6 in. of lateral.

This system is for both air and water wash. The air is supplied from a rotary Root's blower having a capacity of 5,000 cu. ft. of free air per minute against a pressure of 5 lb. per square inch, which gives approximately 4 cu. ft. of air per minute for each square foot of sand surface in a filter.

The wash water is supplied from a wash water tank and is delivered at the rate of approximately 8½ Imp. gallons per minute for each square foot of sand surface.

Filter Sand and Gravel.—The filter gravel in the original pre-filters and in the new filters is deposited in four layers of specified screened sizes to a total combined depth of 15 in.

The filter sand is 30 in. in depth. In the original pre-filters this sand had an effective size of between 0.50 m.m. and 0.60 m.m. and a uniformity coefficient of about 1.65.

In the new filters the effective size of the sand varies from 0.40 m.m. and 0.50 m.m. and the uniformity coefficient is about 1.68.

In the original final filters, there is 12 in. of graded gravel placed in four layers and 27 in. of sand having an effective size of from 0.25 m.m. to 0.35 m.m.

Rate Controllers.—Each of the original pre-filters and final filters was equipped with controllers of the Earl type with a master controller to regulate the entire system. These controllers have given satisfaction in all respects.

The new filters will be equipped with controllers furnished by the Builders' Iron Foundry and will work in conjunction with their new pendulum diaphragm units for loss of head and rate of flow below and their new loss of head and rate of flow gauges on the operating tables in the filter galleries.

These controllers are also provided with master control.

Operating Tables. — All operating tables in the galleries are of the piano type and constructed of gray marble, which makes an attractive contrast with the red tile floor of the gallery.

Clock and Signal System.—The wash water pumps, wash water tank and piping system do not have sufficient capacity to permit of more than one filter to be washed at the same time.

This makes it necessary for the filter operator in one gallery to be kept informed, not only as to the supply of the water available in the wash water tank, but also as to whether or not filter washing is in progress in either of the other two galleries.

It is expected that the clock and signal system will systematize the filter washing and prevent interference in the work of filter operators in the three filter galleries.

This system includes the master clock and signal lights in the superintendent's office, and secondary clocks and signal lights in each of the three galleries, the entire system being electrically operated.

The system is so arranged that when the influent valve to any filter is closed by operating a handle on the operating table, a light will automatically show at the master and secondary clocks and continue to show until the influent valve is again opened; thus completing the cycle of a filter wash.

There is also a switch on each operating table whereby the automatic lighting of the signal from that particular table is cut out, if, for any reason, the influent valve is operated for any purpose except the washing of the filter.

The lights to indicate when filters are being washed are three in number and show red for filters in gallery No. 1, yellow for filters in gallery No. 2, and green for filters in gallery No. 3.

The master clock in the superintendent's office is of the wall type with the three signal lights incorporated in the bottom of the case.

The secondary clocks, suspended from the ceiling in the center of each operating gallery, are double-faced with illuminated dials so as to be easily read from the far ends of the gallery.

The three signal lights are incorporated in the bottom of the bronze case.

The depth of water in the wash water tank is also indicated on the clock in the following manner:

Immediately concentric with the outside of the dial is a ring which is automatically illuminated to show the depth of water in the tank. The total depth of the wash water tank is 12 ft., which corresponds to the hour figures on the clock dial. Therefore, by reading clockwise, the hour figure at the end of the band of illumination will indicate the depth of the water in the tank.

Inter-Phone System.—To still further assist the operators in the performance of their work, an inter-communicating telephone system will be installed.

Telephone sets will be installed in the superintendent's office, clerk's office, in each of the three filter operator's booths, at the electrical operator's desk in the pumping station, in the chlorination building and at such other places as are deemed necessary.

In galleries Nos. 2 and 3 the discharge from each filter enters a gallery effluent conduit which extends the entire length of the pipe gallery and passes through a gatehouse into a conduit which discharges into the filtered water basin.

The water level in the filtered water basin is several feet lower than the invert of this gallery effluent conduit. With water in the filtered water basin at a low level and with a low rate of discharge in the gallery effluent conduit, the discharge ends of the filter effluent pipes would not be submerged, thus allowing entrance of air to the bottom of the filter beds when the water level in the filtered water basin raised or the discharge through the gallery effluent conduit was increased.

To prevent any possibility of air entering the filters in this manner, a water level controller will be installed in the gatehouse at the end of each pipe gallery.

A float operating a pilot valve connected to the piping of the hydraulic cylinder of a 60-in. by 60-in. sluice gate, controlling the discharge of the gallery effluent conduit, will automatically maintain the water level in the gallery effluent conduit in such manner as to keep the filter effluent pipes submerged, and not decrease the available loss of head in the filters.

Chlorination Building and Equipment. —This building is above the chamber through which all filtered water passes on its way to filtered water basin No. 2 and the new low level pumping station.

This chamber is provided with baffle walls to obtain a thorough mixing of the chlorine dose with the filtered water.

The central portion of the floor of the chlorination building is depressed to permit of the installation of weighing scales with platforms level with the operating floor.

The platforms of these weighing scales are of such size as to allow 12 cylinders of liquid chlorine to be placed thereon.

Each cylinder is connected by piping to a manifold which leads to the chlorination control table. This table is of grey marble, of piano type, similar in design to the filter operating tables.

This table houses "Duriron" ejectors and distributors. The suction produced by water under pressure passing through these ejectors draws the chlorine from the cylinders on the platform scales and discharges it into the baffled current of filtered water in the chamber below.

On the top of the operating table are located the necessary gauges and valve controls and also apparatus for testing the water after chlorination.

The building is of sufficient size to permit of the entrance of a truck loaded with cylinders or drums of liquid chlorine, and an overhead travelling crane facilitates the handling of these liquid chlorine containers.

Park Features.—The filtration works and low level pumping station are located on an 80-acre tract of ground between the water supply aqueduct and the city of Verdun. An attractive iron fence, 5,000 ft. in length, marks the boundary line on three sides of the property. There are eight gate entrances to afford easy access to all parts of the works.

The north end of the property has already been made into an attractive park by the construction of driveways and paths, grading and seeding and the planting of trees and shrubs.

Two lagoons, each 50 ft. by 150 ft., with water sprays and several flower beds, greatly improve the appearance of the new low level pumping station.

This year we are grading, seeding and planting about eight more acres; and at this rate of progress it will only require a few years to develop the whole

property. Largely due to the interest shown by the filtration staff during the last few years in the growing of plants and flowers, a small greenhouse, 18 ft. by 37 ft., is now under contract. It is so located that access is available from a covered passage from filter gallery No. 1 and will permit the growing of plants for the outside flower beds and for decorating the filter buildings and pumping station.

Raw Water Supply.—The two river intakes from which the filtration works obtains its supply of raw water are located about 20 miles below the confluents of the St. Lawrence and Ottawa Rivers. The intake normally in use is about 1,200 ft. from shore; the other or shore intake is protected by ice cover in winter and can be used when frazil ice causes trouble in obtaining the required volume from the outer intake.

Both intakes supply varying mixtures of the St. Lawrence and Ottawa River waters, depending upon seasonable and local weather conditions.

The shore water is largely Ottawa River water and carries all the domestic pollution of 12 small towns, except that which is diverted into the Lachine Canal.

From these intakes, the raw water is conveyed by the Montreal aqueduct canal and its lateral conduit, a distance of about five miles to the filtration works. The lower three miles of the Montreal aqueduct now serves as a sedimentation basin with about 30 hours storage at a 100 m.g.d. rate of flow which quite materially reduces the number of bacteria of sewage origin in the raw water before it reaches the filtration works.

As regards physical characteristics, the outside water is more desirable than than from the shore. Turbidity is not a serious problem, as neither river carries much suspended matter except for short periods in the spring and sometimes in the fall.

The normal color of the St. Lawrence River (outside water) is from 10 to 15 p.p.m., while the color in the shore water may reach a maximum of 8 p.p.m.

The operator therefore endeavors to have the intakes controlled in such manner as to reduce as far as possible the entrance of shore water.

Rapid and Slow Sand Filters, 1927.

Total	$27,632.14	$29,216.78	$5,322.22	$2,307.87	$64,479.01	$2.07	100.00

Total filtrate in 1927, 31,125.12 m.g.

—The rapid sand filters show an average bacterial removal of 73 per cent when operated at an average rate of 139 m.g.a.d. without use of coagulant.

The final filters, with a mixture of raw and pre-filtered water in the approximate ratio of 3 to 4 as applied water, show an average bacterial removal of 85 per cent when operated at an average rate of 11.5 m.g.a.d.

The overall bacterial removal by filtration (i. e., before chlorination) was 87.5 per cent.

Chlorination.—The slow sand filter effluent and that part of the rapid sand filter effluent diverted to the filtered water basin to make up the total daily demand on the plant have been chlorinated during the past year at their mixing point in gate house No. 2.

A small sample pump returns chlorinated water from a point in the filtered water basin representing an absorption period of about two minutes. Hourly samples at this point show the residual chlorine content under these conditions to be very uniform.

Occasionally sixteen tests are made in rapid succession. These tests are always within .03 to .05 p.p.m. variation from the standard required and show that the mixture of chlorine is instantaneous and uniform, a condition essential to otbain high efficiency.

The dose is varied to obtain 0.2 to 0.3 p.p.m. residual chlorine after two minutes absorption.

The percentage of Ottawa River water at the intake varies seasonally and may vary daily through the agency of high winds.

The dose increased or decreased as the percentage of Ottawa River water is greater or less, "Straight" Ottawa River water requires seven times as much chlorine as that from the St. Lawrence to insure practical sterility.

The overall removal of bacteria after chlorination for the past year was 99.9 per cent.

Operation Records.—The following tables show the details of operation during the year 1927:

General Characteristics of Water from Plant, Year 1927

Alkalinity Ca Cos	82	60	71
Turbidity, less than	2	2	2
Color	30	7	22
Incrusting solids	12.6	9.3	11.0
Total solids	129.	109.	118.
Bacteria per c.c.	12.	3.	6.
B. coli per 10 c.c., less than	1.	1.	1.

Acknowledgment.—The above is an abstract of a paper presented at the Montreal Convention of the New England Water Works Association.

Philadelphia Engineers Club to Discuss Concrete

A meeting when the subject of concrete construction—roads and structures—will be under discussion will be held at the Engineers Club of Philadelphia, 1317 Spruce St., Philadelphia, on Feb. 19, 1929. There will be two sessions, with dinner intervening. The first session will be from 2:00 to 5:00 p. m. Dinner at 6:00 o'clock. The evening session, 7:30 to 10:30 p. m.

Papers and discussion will specialize on "High Strength, High Early Strength, and Waterproof Concrete, both from a Theoretical and Practical Standpoint in Design and Construction," will be given.

A number of engineers who are prominently identified with this type of construction will read papers and take part in the discussion. Men from New York, Philadelphia, Washington, Chicago and other cities will be present.

Engineers and contractors who are interested in this subject are invited to attend.

The committee in charge is W. H. Connell, Henry Delaplaine, F. O. Dufour, W. E. McComas, P. M. Taylor, T. P. Watson.

A Few Details of Sewage Treatment in Germany and England

Some Comments Based on Recent Personal Observation

By SAMUEL A. GREELEY
Of Pearse, Greeley & Hansen, Hydraulic and Sanitary Engineers, Chicago, Ill.

IN England and Germany, much as in the United States, there is an increasing public demand for cleaner streams and for the return of fish life where this has been driven out. This has resulted in Englnad in the recent creation by Parliament of the River's Pollution Research Board with a notable personnel; and in both countries in an increasing activity in sewage treatment work. Munich is building a very large installation of fish ponds for the final purification of a settling tank effluent (cost 5 million marks or $1,250,000); Stuttgart is enlarging its sprinkling filters; Sheffield is doubling the size of its aeration plant; at Birmingham a project has been approved for bringing the capacity of the pre-aeration works up to 24 U. S. M. G. D. and of the sludge gas engine installation from 150 to 600 H. P.; much new construction may be seen in the Ruhr valley, etc. Some of the more pertinent details are briefly described below—based on recent personal observation.

The sewage of most European cities is, of course, low in quantity and high in concentration as compared with sewage in the United States. But, in addition to this proportionate concentration, the strength of the sewage is increased in many instances by the industrial wastes, which have a marked effect because of the relatively small volume of human sewage. Thus at Bury, the sewage is at times acid and at many cities the characteristics of the sewage change sharply from hour to hour.

Preliminary Treatment.—A special point of interest are the oil removal tanks in the Ruhr valley. It is Imhoff's view that perhaps half the oily matters are attached to particles of suspended matter and are not removed by quiescent flotation. Therefore the sewage is agitated or scrubbed with air to break the oil loose from the suspended matter. Quiescent side-pockets trap the oily matters. The quantity of air is indicated at one-tenth the volume of sewage 0.0133 cu. ft. per gallon and the aeration period at three to five minutes.

In many of the English plants, settling periods of eight hours or more are used. Thus the new settling tanks at Reading, to work ahead of aeration tanks, will have a displacement period of about ten hours. These relatively large settling tanks serve as balancing tanks tending to make both the rate of flow and character of sewage more uniform. Further, experience seems to indicate a coagulating process in the settling tanks which tends to wash out some colloidal matter and so better prepares the sewage for further treatment.

In the Ruhr valley, separate sludge digestion tanks are being used in conjunction with deep 2-story tanks having relatively small sludge compartments. It is held that the sludge is concentrated in the 2-story tank, thus requiring much less volume in the separate tank; and that the temperature and reaction of digestion can be better controlled in the separate tank. The combination of the two is thus favorable as to both economy and efficiency.

Sludge Digestion.—The digestion of sludge in separate tanks appears to be gaining in favor somewhat slowly, but along sound lines. The oldest separate digestion works visited were at Birmingham, first started in 1909; the most recent were in the Ruhr valley. Most of the digestion tanks were characterized by having relatively flat bottoms as compared with practice in the United States. Bottom slopes as flat as 1 in 100 were used. The sludge is withdrawn by gravity or by pumping, but sludge pumps are generally provided for circulating sludge and for mixing ripe and fresh sludge. In fact, a sludge pump appeared to be required for good operation and the intimate mixture of ripe and fresh sludge was often regarded as an essential routine procedure and was accomplished by passing them together through the pump. The proportions of the two sludges in the mixture varied of course, even at the same plant, but approximated one part of ripe sludge to from 3 to 5 parts of fresh sludge.

It seems to be accepted that the best way to heat the sludge is by pumping hot water into it. This was done in the Ruhr valley, at Stuttgart, and occasionally, in very cold weather at Birmingham. The temperature of the hot water supply at Stuttgart was 150° F. and at Essen Relinghousen upward of 185° F. The water was heated by burning the sludge gases and was relatively small in quantity, the indication being that the radiation losses were not considerable.

A variety of covers were in use. The floating sectional concrete covers at Birmingham made a very favorable impression. As Essen Relinghousen the digestion tank has a fixed concrete cover with a circular opening about the circumference which laps over a triangular corbel built out of the side wall, much like the traps in a 2-story tank. The fixed concrete cover was submerged about 2 ft. with scum, but there was little or no escape of gas. At Stuttgart a flat arched slab was used. However, there appeared to be little fear of odors from open digestion tanks which were being adopted for some new installations.

Sludges from primary settling tanks, final settling tanks and excess activated sludge were all returned to the digestion tank, but the weight of practice favored the delivery of the final and wetter sludges to the incoming sewage, to be settled out and recovered with the primary tank sludge and then discharged into the digestion tank. Their moisture content was thus reduced and Imhoff suggests a capacity of 2 cu. ft. per capita for digesting both primary and final sludge, one-third being in the 2-story tanks.

Sludge Gas.—Gas from the digesting sludge is being caught, measured, and used. In some cases the gas is used only for heating the water which is pumped into the sludge tank as at Stuttgart and Essen Relinghouse. But at Iserlohn in the Ruhr valley all the power required for the operation of the sewage plant is made by the operation of a small gas engine working directly on sludge gas. At Birmingham a 150 H. P. gas engine has been working directly on sludge gas for the last nine months and an additional 450 H. P. unit is about to be installed. The gas is not cleaned in any way and there is no gas holder, the only storage being in the gas catchers floating on the sludge. It was stated that there had been no evidence of pitting during nine months of almost continuous service. It is estimated that the sewage of Birmingham (close to one million people) will yield enough sludge gas to produce 1,000 brake horse power.

Extensive detailed information relating gas quantities to weights of organic matter, temperatures of digestion, and the like cannot be acquired in a short visit. The following round figures, however, were given for sludge from primary settling tanks:

Place	Gas in Cubic feet per capita
Ruhr Valley	0.37—0.28
Stuttgart	0.32
Munich	0.47
Birmingham	0.41

In the new (1928) edition of his hand book, Imhoff gives an excellent typical computation of gas quantity based on organic matter under digestion and the conditions of digestion. Thus (page 67) on the basis of 15 grams per capita per 24 hours of organic matter in the settling solids, the actual quantity of gas is 0.37 cu. ft. (10.5 litre) per capita per 24 hours, of which Imhoff estimates 0.28 cu. ft. may be developed in routine operation.

Biological Treatment.—Aeration by mechanical agitation has been in operation in England for three to four years and its use is continuing. The paddle wheels at Sheffield have been treating 9.6 to 12. U. S. M. G. D. of settled effluent for nearly four years with, apparently, marked success and the installation is now being doubled in size. The plant makes a most favorable impression. Simplex aerators have been in operation at Bury for over three years and are being installed in several other places. Plants using air are also being built and there seems to be no preponderance of opinion. Perhaps, on the whole, more aeration plants are being built at the present time with mechanical agitation than with air and in the Ruhr valley a combination of air and paddles is successfully used in the same tank.

Sprinkling filters are still in use for two-thirds of the sewage at Bury and new units have been added at Birmingham within the last year. There seems to be no disposition to discard them in favor of the activated sludge method and many can be seen in operation in England. In a general way, comparative total annual costs of sprinkling filter and activated sludge plants were not far different from the trend of such costs in the United States, the total annual costs being about equal when power costs around 1 ct. per kwh.

The partial aeration of the sewage between the settling tanks and sprinkling filters at Minworth has been successful and the capacity is being extended from 9.0 to 24.0 U. S. million gallons per 24 hours. The sewage is agitated in contact with activated sludge by air and paddles for one hour in channels having a cross-section of 18 sq. ft. and a flow length of 3,300 ft., and then settled in upward flow settling tanks. The sludge is reaerated with air for 10 hours at the rate of somewhat over 1.5 cu. ft. per gallon of sludge. This pre-aeration has permitted an increase of the quantity of sewage applied to the filters of about three times.

There is no indication of projects to process activated sludge to a fertilizer base in England or in Germany.

I was told in England that the cost of a complete treatment plant was not far from 2 pounds ($10) per capita of rated capacity.

The new filters at Minworth (Birmingham) have been equipped with travelling disturbutors on rectangular beds. I gathered that operating experience with travelling and fixed spray distributors indicated that a somewhat greater load could be handled by the filters with the travelling distribution. It is interesting to see sprinkling filters at Birmingham which have been in continuous operation for 25 years without any marked deterioration of the filtering material. Broken granite, coke breeze and broken gravel are used. Some of the filters have a top layer of fine gravel (about ¼-inch size), some 12 in. thick.

Final Sedimentation.—I found more common use of deep upward flow tanks for final sedimentation than of any other sewage treatment device. Such tanks are generally built square or round, perhaps 30 ft. in diameter and 25 to 30 ft. deep. The aeration tank or filter effluent is discharged at the bottom of a relatively large vertical

flume and generally not over 10 to 12 ft. below the surface. Weirs, built very accurately, are provided on all sides for taking off the clear liquor. The settling periods in these tanks were not generally over two hours, but the upward velocity computed on a displacement basis was the more usual index of size, the following figures being typical:

Character of sewage	Limiting Upward Velocity in ft. per hour
Crude or screened sewage	14.0
Filter effluent	10.5
Aeration tank effluent	4.5

With aeration tank effluent, the sludge was withdrawn continuously, the rate being controlled by a valve on the outlet pipe and the quantity measured by a weir between the outlet pipe and the sludge return pumps. At Essen Relinghousen, the sludge was passed through a fine screen (1 mm. mesh) before it was returned to the aeration tanks. The material retained by the screen and washed off with a stream of sewage was coarse and fibrous and was considered to contain little active sludge. It was pumped to the sludge digestion tank with the excess.

General.—The visitor is especially struck by the generally fine appearance of the Europeon sewage works. Most of them have attractive buildings and considerable planting including shrubs, vines, and flowers. Except where there was little or no attempt to digest sludge, odors were not in evidence, partly because of the fresh sewage and partly because of the clean condition of the plants.

There is a considerable range in the methods of treatment and the loadings as illustrated by the long displacement period in the English settling tank as compared with the short ones in the Ruhr valley works. The relatively low per capita quantities of sewage, brings more ample capacities within financial reach and the plants as a whole appeared to be less heavily loaded than many in the United States. Thus the strong sewages at Decatur and Ft. Worth, which approximate the strength of the Birmingham sewage, have nearly four times and twice the per capita rate of flow respectively.

Note should be made of the care given to the distribution of the sewage to the various units by vertical swing gates, weirs, and orifices. At Birmingham the inlet pipe to each settling tank is flanged and a vertical plate orifice inserted between the flanges with a valve on the inlet side. A U tube indicates the loss of head through the orifices and this loss is kept the same at each inlet throughout the battery of tanks.

Other points of interest related to the conveyor machines for removing sludge from drying beds at Stuttgart and Munich; and the general use of some form of storm water treatment.

The Beccari Plant at Scarsdale, N. Y.

Fermentation Process of Disposing of Organic Waste

By ARTHUR BONIFACE
Village Engineer, Scarsdale, N. Y.

IN THE choice of a method for garbage disposal, local conditions must of necessity govern the type selected and the fact that these conditions are different in almost every locality calls for the guidance of competent technical talent to solve the problem.

Why the Type Was Selected.—Perhaps the most difficult situation to meet is the one presented by the high class built up community with a population of about 10,000. Lacking an appropriate district to choose as the site for a disposal plant, the unmost caution must be exercised for fear of the effect its establishment would have on adjacent property.

It is under the latter category that Scarsdale takes its place and explains why the choice of plant fell to the one selected. Scarsdale is located about six miles north of the northern limits of New York City. It is known as one of the highest type residential communities in the east, has a population of about 9,500, embraces territory over six square miles, and has an assessed valuation of $50,000,000. Prior to 1923 its household wastes were removed by 15 private collectors, with the usual indifferent service that accompanies a method lacking governmental control. Therefore, during the summer of that year the municipality took over the collection and disposal of waste, and after extended study chose for the disposal of its organic waste, a plant patterned after the fermentation type much used in Italy. Its choice, primarily, was due to the fact that the building lent itself to architectural treatment, was simple to operate and further, that a humus could be produced bearing high value as a fertilizer.

To those not familiar with this method of disposal it may be stated that the Fermentation System established in Italy in 1914 first contemplated the reclamation of organic waste accumulated on farms, with a view not only to its salvage, but to an increase in its effectiveness as a fertilizer. Later the system was successfully applied to the disposal of organic waste produced by municipalities.

The plant erected in Scarsdale was an eight cell unit constructed of concrete, the design being practically identical with the units in use in Florence, Italy.

No reference will be made to the details of design, followed in the original structure built in Scarsdale, for reasons that will be obvious later.

Early Operating Results.—The plant commenced operation in December, 1923, following closely the methods employed in the Italian cities, viz., cells were charged to capacity with organic matter, hatches and side doors closed, and the contents left undisturbed for periods varying from 45 to 60 days, at the expiration of which the residue was removed and stored in the side sheds built as a part of the plant.

The humus produced in the early operations contained about 45 per cent moisture and on removal from the fermentation chambers emitted decidedly objectionable odors; moreover, it bore no resemblance whatever to the humus produced in the Italian plants, and although subsequently it was dried and ground and the work and nuisance involved in so doing made it undesirable to continue.

Numerous studies, investigations and experiments followed, all of which form an interesting chapter in the development of this means of disposal. It should be stated, however, that the early operation of the plant fell short of expectations, first—because, filling a chamber 9 ft. high with wet garbage resulted in producing a mass impervious to air, which was fatal to success, and second—the various components of our raw garbage seemed to produce an acid condition detrimental to the development of the biological processes.

The design and operation of a fermentation plant do not call for any complicated technique, only the observance of two fundamental principles, which are, neutralization of the mass and sufficient means of aeration in the cell after the mass has passed its initial stage of decomposition.

Details of Reconstructed Plant.—As reconstructed, the plant in Scarsdale consists of an eight cell unit, each chamber having a capacity of 20 cu. yds. The floor of the cell is graded so as to drain the liquid to the sump or sewer below. The interior is divided into five layers by means of gratings, spaced 18 in. center to center. These are constructed of 2 x 3 creosoted pine for ease in handling. Two small port holes for the admission of air are located just above the floor, and in the roof a six inch hole is provided for the passage of the gases generated in the mass below. There is a hatch on top for charging and a sliding door on the side for discharging. Connected to the outlet in the roof is an air washing chamber two feet in diameter and 10 ft. long in which a series of sprays are located; these are operated by a one inch centrifugal pump, and a one-third H. P. motor connected to a 50 gal. tank, charged with a 1:500 solution of potassium permanganate. The object of this washer is to remove any possibility of nuisance due to the emanation of gases from the mass during its early anerobic stages.

Practice at Scarsdale.—The practice followed in Scarsdale is to bring the raw garbage to the floor formed by the

roofs of the cells; here it is dumped and spread, and commercial hydrated lime in proportion of about 1½ per cent by weight is added to effect neutralization. To stimulate anerobic action a small quantity of ammonium sulphate in the form of a 10 per cent solution is poured over the mass. The garbage is then shoveled into the cell, and the process described repeated until each chamber is filled.

Immediately after closing the cell, a vigorous nitrifying action is noted, and the temperature gradually rises, until about the third day it has reached around 150 to 155° F., which it holds for three or four days, then slowly drops, according to the season of the year, to 110 degrees at the 30th day, when the residue may be removed, ground and bagged.

The quantity of humus obtained from one cell is 12 to 16 per cent by weight of the original charge, and when analyzed averages:

Nitrogen	2.59 to 3.00 per cent
Potash	0.60 to 1.76 per cent
Phosphoric Acid	2.64 to 3.50 per cent
Moisture	10.00 to 12.00 per cent

The humus is sold wholesale at $25.00 per ton, which yields a net revenue of approximately $22.00 per ton after deducting cost of treatment.

The procedure just described might give the impression of being involved, but all operations are conducted by common labor only.

Briefly summarizing, the process divides itself into two interrelated treatments. In the first stage, the garbage is enclosed in a cell against the access of air, thus stimulating the action of the anaerobic bacteria which cause the mass to break down and liquefy the readily decomposable elements. Passing into the second stage, the mass is subjected to a current of air at atmospheric pressure initiating the action of aerobic bacteria. The flow of air admitted through the small portholes and thence through the mass not only stimulates aerobic action, but tends to dry the contents of the cell, and finally a good grade of fertilizer is obtained, free from noxious odors.

Cost.—As to the cost of such plants, figures will differ according to locality, but roughly estimated, the cost is $2,000 per 1,000 population, or $20,000 for a village or city of 10,000. It would be well, however, to have several cells in reserve in case of emergency, which would add to the unit cost proportionately.

In designing the individual cells, a size should be chosen that would provide for its being filled within 48 hours, otherwise there is a chance of arresting the vigorous nitrifying action that commences almost immediately after the first two or three loads of garbage are deposited in the cell.

Important advantages over other methods of disposal are low initial cost low operating and maintenance costs, absence of noxious odors due to operation, complete destruction of the pathogenic germs, its high revenue producing possibilities, and ease of enlargement of plant without disturbance of original unit, as the municipality grows.

Its disadvantage is that it is essential to maintain the three-can system which in some localities might introduce considerable difficulty in the collection phases. It is necessary also to make provision for the consuming of combustible waste, but in the complete plant design there should be no difficulty in incorporating this feature. Putting it broadly, a fermentation plant accomplishes in one month what the old compost heap took a year or more to do, and does it minus the nuisance.

As has been pointed out, garbage disposal by fermentation is not new, Italy has used it for 14 years. What is new is the adaptation of the process to American conditions, which differ vastly from those of Italy, and, therefore, present serious difficulties not faced there.

Acknowledgment.—The above paper was presented at the 9th Annual Conference of the International Association of Street Sanitation Officials.

Horn Controlled Traffic Signal

Sound and light assume a unique duty as traffic policeman in a new scheme of control whereby the operation of traffic lights at certain outlying intersections is to be placed in the hands of the traffic itself. Under this plan it is claimed vexatious halts at isolated intersections when there is no cross-traffic for which to halt will be entirely eliminated. And pedestrians, accustomed to taking their chances at street crossings, are also cared for; in addition to allowing cross traffic to interrupt main traffic. the new system enables pedestrians to obtain right of way by pushing a button.

The automobile horn is a vital factor in the plan, devised by Charles Adler, Jr., of Baltimore, and being introduced by the General Electric Company. The sound of the horn starts an electric sequence that changes the lights.

Approaching a much-traveled main artery, the motorist in the cross-street finds himself stopped at the street-intersection by a red signal-light, and knows, of course, that the signal-light on the main avenue is green. He halts his car near a horn-like contrivance mounted on a pole at the curb. He honks his auto-horn.

Immediately a sensitive microphone inside the sound-collector on the pole picks up the noise, converts it into an electrical impulse, transmits it by wire to a control-box, and which operates the mechanism to change the lights.

The first thing that happens is the appearance of an all amber light in the lens below or adjacent to the red light,

Horn-Controlled Traffic-Signal Installation at Schenectady

informing the motorist that his signal has registered. A moment later he gets his green light, a red light appears on the main thoroughfare, and the cross-street car secures the right of way.

After a premeditated interval, the lights change back from red to green on the main avenue and from green to red on the side street. The timing cycle operated by the sound-controlled device is completed shortly thereafter, main traffic retaining the uninterrupted right of way at that particular intersection until the next cross-bound vehicle appears.

In case a second motorist, travelling through the cross-street, reaches the intersection just after the lights have changed back to favor main traffic, he cannot immediately get the right of way, even though he blows his horn at the sound collector. He sees the amber light, indicating his signal has registered, but the red light against him continues until the timing cycle is finished, whereupon he also receives a green light, main traffic receiving a red light.

There is also provision for push-buttons on the poles, so that pedestrians can operate the system and obtain the right of way when desirous of crossing main-artery traffic.

Several initial installations of the device, known as the G-E novalux traffic-operated controller, are already under way. It is expected to be particularly useful at outlying street-intersections and upon country highways.

State Aid for City Highways

In a very interesting letter, published in the December issue of ROADS AND STREETS, Mr. J. H. Howe, City Engineer of Cresco, Iowa, comments upon our editorial article, "Why States Should Build Pavements Through Towns."

Mr. Howe says: "Heroic efforts are being made to get the country roads out of the mud, while in the cities and towns we are still in the ox team days so far as any legislation calculated to speed up the construction of modern paved streets is concerned." This is true, and our editorial article emphasized one aspect of the legislative problem, namely a more equitable distribution of the cost burden. We are convinced that there will be inadequate progress until the practice of assessing street construction entirely against abutting property is discontinued.

Mr. Howe points out that the "city fathers" are usually less to blame than the state legislators for the prevalent injustice of laws relating to taxation for street improvement. He adds:

"Many members of the legislature seem to find it better and safer politics to neglect the cities and towns, but have them pay the bills. They talk farm relief but not city relief."

There is a growing irritation among city residents over the distribution of gasoline tax money, for example. They complain that in many states the residents of cities pay more than half the gasoline tax, but get only a very small percentage of the benefit derived from the tax. We predict that this complaint will grow in volume until state legislators do give adequate attention to "city relief." As a first step in that direction we urge the improving of "through streets" with money raised by gasoline and other motor vehicle taxes.

We agree heartily with Mr. Howe that if state-aid is thus extended to cities and towns, it should not be limited to building street pavements only 18 to 20 ft. wide. A city street should not be treated like a country road. If state-aid is extended to cities and towns, state highway departments may well delegate to city engineers much of the designing and construction supervision of state-aid streets. Co-operation, in short, is needed between state and city engineering forces.

We may have been too severe in our criticism of the seeming inertia of the "city fathers" relative to changes in the practice of assessing street improvements. Where they are hampered by state laws, the inertia is not theirs alone. Yet it rests mostly upon them to initiate efforts to change the state laws. Perhaps city engineers themselves are even more responsible for the inertia than are the "city fathers."

A city engineer should be more than a technical expert on construction and maintenance of city works. His is also the province—if he will but assume it—of advocating economic reforms even in laws. No one knows better the defects of a law than the men who have to conduct their work under its prescriptions and proscriptions. The city engineer sees such defects almost daily, and he chafes under them. But the old conception of an engineer as purely a technician usually prevents city engineers from aggressively advocating changes in laws, for that is supposed to be a job for legislators.

Engineers who, like Herbert Hoover, have risen to high executive positions, have usually taken a very broad view of the province of engineering. They have regarded all phases of their economic problems as being essentially engineering, regardless of the prevalent practice.

If engineering is the application of science to problems of economic service, engineers should not hesitate to extend their activities into the uttermost parts of the social realm. Certainly there is as much need of scientific study of the economic effects of laws and ordinances as of the scientific study of strains and stresses. Who, we ask, is better equipped for such study of political economics than is the engineer?

"Engineering Schools Should Teach Economics"

Under the title "Engineering Schools Should Teach Economics" a recent editorial article in an engineering magazine criticized some alleged errors of an engineer and placed the blame for his alleged mistakes upon his apparent lack of training in economics. We agree with the editorial opinion that engineering colleges should teach economics; but we think that the editor in question himself exemplifies the very lack of economic training that he deplores.

The first criticism of the engineer by this editor was that he used 7 per cent instead of using about 5 per cent in computing interest charges on a municipal pumping plant. This criticism was probably correct if the municipality could borrow money at 5 per cent without straining its credit. Not infrequently engineers of railways, on the other hand, make the mistake of using a bond interest rate of about 5 per cent instead of using a "fair return rate" of about 7 per cent.

The second criticism was that the engineer had used a 7 per cent annual depreciation rate; and this editorial statement was made: "Now, if a depreciation charge is set up, the invested capital decreases each year by this amount. Consequently, the interest should either be calculated on the basis of a diminishing capital or a diminishing depreciation."

Neither the premise nor the conclusion is correct. If a depreciation charge is set up and if a sinking fund is established to retire the plant at the end of its life, both the capital investment and the depreciation rate should be regarded as constant. This is the ideally correct treatment of depreciation where no change in price levels occurs. An approximately correct method consists in using a depreciation rate determined by dividing 100 by the estimated life in years, and in that case an approximately correct result is obtained when the invested capital is reduced each year by the amount of the annual depreciation found by multiplying the "straight-line" rate by the original cost (not the depreciated value) of the plant. On short lived property this approximate "straight-line" method is often satisfactory enough, but on a long lived plant it leads to very incorrect results, for it is tacitly based on the assumption that the depreciation annuity can earn no interest, which is clearly erroneous.

The third criticism of this engineer is even more clearly wrong than the second criticism, yet it exemplifies one of the commonest of economic blunders. Says the editor: "To make the situation still more illogical, when comparing the cost of operation of the present plant and purchased energy, this engineer ignored the fixed charges on the present plant when estimating the cost with purchased power, even though the investment still exists in the shut down plant."

Here we see that the critical editor regards the original cost of an obsolescent plant as being an element that must be considered in ascertaining whether it is cheaper to retire it or buy electric current from a central station. As a matter of fact it is wholly immaterial what the original plant did cost. The problem differs radically from one in which two alternative new and rebuilt plants are being compared economically, or from a problem in which the cost of generating power with a proposed new plant is being contrasted with the price at which such power can be purchased. In the case of an old plant that is obsolescent, the problem is really whether its obsolescence has progressed so far that its true economic value is less than its scrap value, or not. If not, it should continue to be operated, even though its true depreciated value be but little more than its scrap value.

Stated differently, the problem then is to ascertain whether the operating expense (exclusive of interest charges) per unit of power generated by the old plant is greater or less than the price per unit of purchasable power.

The problems of depreciation and the allied problem of when to retire an old plant or plant-unit, have been discussed in the "Handbook of Mechanical and Electrical Cost Data" by Gillette and Dana, to which the reader is referred for full proof of certain of the statements above given.

In the course of a rather extensive experience, the editor has found more ignorance among engineers on the problems above mentioned than on almost any other economic matter.

Because of ignorance of economic facts and principles hundreds of millions of dollars worth of plant have been retired too soon, and other hundreds of millions have been kept in service too long. To emphasize the seriousness of the whole matter, we have just quoted from a prominent engineering magazine a criticism of an engineer in which the editorial critic displayed his lack of understanding of certain principles involved.

It is apparently the opinion of the majority of teachers of engineering that there is no necessity of teaching economics as a special subject, and that all the principles of engineering economics can be learned incidentally as a sort of by-product of one or more of the engineering studies. It should not be difficult to test this opinion by submitting the fourth year students to a thorough examination in economics. It may be that the editor has been peculiarly unfortunate in having employed so many graduate engineers who could not pass such examinations.

Ask a number of such questions as this: How would you determine what rate of interest to use in capitalizing annual expenses? The answers that the editor has received have almost invariably shown no appreciation that it is a real problem itself to determine the correct percentage. Throughout Wellington's "Economic Theory of Railway Location" a bond interest rate is erroneously used to capitalize annual expenses and to estimate that part of fixed charges that relates to interest. In the original appraisal of the franchise value of the railways of Michigan and Wisconsin, a bond interest rate was erroneously used in capitalizing net earnings.

There seems to be prevalent the idea that if correct principles are applied it is a matter of minor concern whether the alleged facts are correct. Last year's net earnings, for example, are often assumed to be typical, without a thorough study to show what is a typical year's net. Depreciation rates are guessed at, although usually they may be ascertained with considerable accuracy from past accounting records that are properly interpreted. Here again very few engineers that the editor has encountered in rate cases know how to derive a depreciation rate from past accounting records; most of them asserting it to be impossible because in the earlier years no distinction at all was made between maintenance expenditures and retirement (depreciation) expenditures. The problem can be readily solved none the less.

Like any other subject that attains the rank of a separate branch of science, economics should be studied by itself. Unfortunately that particular branch of economics known as political economy has come to be regarded by many as being the only economics. For the most part it still remains a mass of unproved hypotheses and hot air. Business and engineering economics, on the other hand, have largely emerged from the stage of unproved hypotheses. Still the data that must be inserted in the formulas are often woefully unsatisfactory. The lives of many kinds of machinery and structures are usually guessed at. Interest rates are guessed at. Even unit cost prices are often guessed at. Overhead percentages are often guessed at. All this, too, by many engineers who would be shocked at hearing themselves called economic ignoramuses.

If this state of affairs is not traceable to the by-product treatment that economics has received in many engineering colleges, then what is the cause of it?

The Personnel of a Water Department

How Detroit Provides for Its Employees

By JOS. F. MAJESKI
Paymaster and Personnel Superintendent, Department of Water Supply, Detroit, Mich.

IN the operation of the department of water supply, the city charter places all employees within the jurisdiction of a civil service commission. This commission acts in a capacity similar to the employment bureau of a private organization, furnishing upon request from the personnel superintendent all technical and clerical help which may be required in the course of operation of the department. The civil service commission, upon receipt of requisition, certifies the first person from a list composed of eligibles who have successfully passed a competitive examination for the position which is desired to be filled. Also, all changes that may affect a certified employee's status must be submitted to the civil service commission for approval. Employees have the privilege of protesting dismissal and suspensions and may, if desired, request a hearing before the civil service commission.

Therefore, it can be readily understood that the problems involving the personnel department of the water supply are the same as those confronting other similar municipal and private organizations. Material effect of questions arising, relating to the successful operation of this department must be considered carefully and judiciously the same as other problems which directly apply to the department of water supply.

A person certified to a position in the department, and upon entering, is required to fill out an employment record card containing name, address, telephone number and other data, which gives the department immediate information for record acknowledgment. These records are visibly typed and filed for instant reference, showing every transfer, promotion or change; in reality, giving a working history of the employee from the date of entrance into the department.

How Vacancies are Filled.—Inspiration to extend every effort for best results and co-operation in the department is instilled in all employees by the fair treatment accorded them. In the course of operation of such a vast department vacancies occur within the various bureaus. These positions are filled in so far as possible from the ranks of the existing personnel, thereby affording the individual to qualify for whatever promotion may occur as a result of transfers, dismissals, resignations or promotions. This procedure is followed, within the jurisdiction of the civil service commission, by filing an application setting forth his or her reasons as to their particular adaptability to perform the duties of the position which has become vacant or newly created. This application, with all other records of the employee already on file, is considered by the head of the bureau in which the vacancy occurs, and forwarded to the personnel superintendent for his approval and recommendation to the civil service commission, who has final jurisdiction in the matter.

The benefits realized by enabling employees to rise in the department by promotion or transfer creates a keener interest in their work as well as the spirit of competition, knowing that upon them depends every effort of success or failure, thereby encouraging and obtaining the best results for co-operation, and ultimately successful operation of the department.

Conditions provided for the betterment of the employees and for the consideration of their services are well taken care of by granting adequate periods for vacations and illness, as well as general environments.

Vacations and Sick Leaves.—All employees in the service of the department continuously for one year are allowed two weeks' vacation with pay. Time of vacation periods is apportioned by the head of the bureau in such manner so as not to impede the operation of the department. In case of illness, an employee is allowed as many as 15 days' leave with pay absorbed during the period of the year, or necessitated continuously. If an employee is compelled, by reason of serious illness, to absent himself or herself for more than the usual 15 days' sick leave, then with the discretion of the board, an additional 15 days is allowed with pay. Any employee absent by reason of illness or otherwise is required to notify the head of his or her bureau within 48 hours, stating reason for such absence and probable date of return. A physician's certificate must be furnished in case period of illness exceeds more than three days.

The Working Day.—The city charter provides that eight consecutive hours constitute a day's work and that six day of eight hours each constitutes a week's work. Overtime is paid per diem employees at the rate of time and one-half after the completion of the eight-hour day and double time on Sundays, provided they have already completed a full forty-eight hour week, or six consecutive days of eight hours per day.

The magnitude of the responsibility of the pay roll bureau can only be appreciated by the fact that from Jan. 1, 1927, to Dec. 31, 1927, this bureau paid out in salaries and wages the sum of $4,650,471.72. The weekly pay roll, made up for an average of about 2,200 employees, amounted to $3,623,372.75, while the semi-monthly pay roll for an approximate average of 477 employees amounted to $1,027,098.97 for the same period.

The above figures give one an understanding as to the accuracy, with several processes of checking, required in the detailed routine of the execution of this work.

The Pay Roll Bureau.—All timekeepers report to this bureau every Monday morning with their time sheets, which are in loose-leaf form, to be checked in the timekeeper's presence, as to names, titles, rates and extensions. Any change in title or rate, within the ruling of the department, must be authorized by the superintendent of the division which the timekeeper represents. The rates of pay in all cases are required to be within the standard adopted by the board in their respective classifications. When pay rolls are checked and completed, they are subscribed and sworn to by the head of each division or bureau before the personnel superintendent, who is a notary, and then submitted to the civil service commission for checking as to names and tiles, thereafter passed on to the city controller for verification of extensions, and finally to the city treasurer for preparation of the checks. Upon receipt of the checks from the city treasurer, they are checked and numbered by this bureau to correspond with the pay roll. After this procedure, they are then ready to be issued to the employees on pay day. Any employee receiving his check must furnish a signed pay ticket, showing such receipt, which ticket is given him by the timekeeper, who procures same from this bureau.

Provision is also made in this bureau for the handling of discharges and lay-offs. During the last year 688 employees were either discharged or laid off, necessitating the amount of $15,-402.52 to be paid out in cash. It has been the policy of this department to pay off employees immediately upon discharge or lay-off.

Handling Complaints.—The department of water supply in its operation also comes in contact with almost all the citizens, business and industries of the city. Considering the number and diversity of interests encountered, it is to be expected that a number of complaints will be made in the course of each year. These complaints are principally those regarding water and service charges, those regarding the personnel and those involving property. Minor complaints regarding charges for services are mostly adjusted by the billing department, but the more difficult complaints are adjusted by the adjustment committee, which is composed of four members, namely: the general manager, engineer of water system, chief clerk, and the personnel superintendent, which committee in turn makes their recommendation to the board of water commissioners for their approval.

All complaints against employees of the department are referred to the general manager and by him placed in the

hands of the personnel superintendent. These complaints, though few in number and of minor nature, are given a most searching investigation and if the employee is found to have been guilty of the charges made, he is severely disciplined. Complaints involving property are seldom made, as those in charge of the department's construction and maintenance divisions are most solicitous not to injure any property in the proximity of their work. If it becomes necessary to destroy lawns or walks in the course of operation, immediate steps are taken to repair the damage.

Accidents.—In a business as large as that conducted by the department of water supply, in spite of all precautions that are taken, accidents do occur, but they are mostly of a minor nature. In the first place considerable time of the personnel superintendent is devoted to looking after accidents in which the motor equipment of the water department is concerned. A written report is made out by the driver and forwarded to the personnel superintendent and by him reported to the superintendent of city motor traffic division, after which a date for hearing is set and all parties involved are notified to appear for hearing in the city council chamber. This department is represented at this hearing by its personnel superintendent, who has prepared himself by personal investigation of the facts of the accident. If the employee is found guilty of negligence he is disciplined and compelled to pay the damages caused. Other automobile accidents occur at times when a car is damaged by coming in contact with the department's construction or maintenance work. An automobile may be driven into a trench or over a pile of dirt or material that has been placed in the roadway. These cases are investigated and if the department is found at fault compensation is allowed for the damages sustained. The employee at fault in such cases is severely disciplined. There were 110 accidents for the year 1927 which were disposed of as follows: Twenty-five city drivers were found at fault; forty-two private parties at fault, and forty-three were unavoidable.

Accidents to employees are given a most searching investigation. These accidents are not very numerous and when occurring are usually of a slight nature. Fatal accidents or accidents occasioning total disability are of rare occurrence. During the year ending Dec. 31, 1927, there was a total of 408 accident cases handled by the personnel superintendent. Every accident, no matter how trivial, must be reported and on the eighth day after this report, together with such data as the name, address of both the employer and employee, occupation, age and sex, date and time of day when accident occurred and the nature and cause of the injury, length of time lost, date of return to work, the name and address of the physician and hospital, and the amount expended for hospital and medical care, must be submitted to the State Industrial Accident Board.

Accident Compensation.—The department of water supply, under the state law, does not pay compensation unless the employee is disabled for a period longer than seven days. When an employee is not able to return to his work after seven days, additional information must be furnished to the state board, covering the question of compensation for the injured employee. During the past year there were 39 compensable cases and 360 non-compensable cases, constituting 408 accidents to employees. The compensable cases receive 60 per cent of the weekly wage, the amount not to exceed $18 per week. Should an employee lose a limb through accident, a fixed time during which compensation must be paid is set by statute. The loss of a hand calls for the payment of the compensation for 150 weeks. Should death result through accident, the person's dependents are entitled to 300 weeks' compensation. The total amount paid during the year amounted to $6,124.88, distributed as follows: Compensation for minor injuries, $4,668.88; to widows of men who have lost their lives, $1,456. Besides the compensation, the department is responsible for a certain amount of medical attention and hospital expense in all cases. It is the personnel superintendent's duty to see that this provision of the law is scrupulously complied with. The sum of $9,047.90 was expended for hospitals, doctors and medicine during the year. The personnel superintendent, in making his reports, must be absolutely fair, in order, on one hand to protect the department, and, on the other hand to see to it that no injustice is done the employee in the time of his great need. All hearings that come up before the state accident board are attended by him. He also arranges all payments concerning matters of compensation.

Acknowledgment.—The foregoing is taken from a descriptive survey of the Detroit Department of Water Supply, issued last October by the Board of Water Commission.

Cost of Operating Ford Runabouts.—During the fiscal year ending June 30, 1928, the Water Department of Pasadena, Calif., operated 13 Ford runabouts. The average cost, according to the 13th annual report of the department, was as follows:

	Per Mile
Tires and tubes	$0.00614
Gas and oil	.01142
Other material	.00506
Labor	.00954
Overhead	.00252
Depreciation	.00205
Total	$0.03733

The average mileage was 7,731. The average mileage per gallon of gas was 15.02 and per gallon of oil 513. The average total number of hours in service during the year was 1,980 and the total cost per hour was 14.58 cts.

How Cities Can Make Use of Wasted Space

By E. E. DUFFY

Cities in the future must give more attention to the elimination of waste space.

Of the several conditions hampering cities, now that the automobile has complicated transportation problems, one of the most in need of corrective measures is the elimination of "Chinese Walls" accumulated through the construction of retaining walls and fills by electric and steam railroads. It has long been the custom in elevating railroad tracks to build parallel retaining walls, filling in between them with earth, with occasional openings at street intersections.

Traffic authorities point out that barriers formed by such construction are not in keeping with modern needs. Instances are cited to show that this space under the tracks can be utilized to the advantage of both railroads and the general public. Such space, frequently valued at $250 or more per running foot, can be made available through simple and economical construction of supporting columns and deck.

Three uses for this space are apparent; business, parking and automobile traffic arteries.

In the Wilson Ave. section of Chicago, space beneath the electric elevated lines has been successfully converted into business property. This improvement benefits both the railroads and the public.

An excellent example of the use of space that otherwise might be wasted is at the East Orange, N. J., station of a large railroad. Underneath the elevated tracks and near the station provision has been made for the parking of numerous cars.

Engineers point out that where four tracks are elevated, the ground space under the superstructure is about 60 ft. wide. With the proper spacing of the supporting columns, at least three cars can be parked for each 8-ft. length. The yearly income from this 8 ft. of land would be equivalent to the annual interest income from $3,000 to $4,000 and in addition motorists would have a convenient place to park.

This 60-ft. width could also be utilized as a thoroughfare for automobiles, with room for two or three traffic lanes traveling in each direction. With traffic congestion in many cities costing almost unbelievable sums, it is entirely logical to expect cities and railroads to co-operate for such usage, traffic planners declare.

Automatic Self-Cleaning Grit Chamber

A New Development for Sewage Disposal Plants

AN automatic, self-cleaning grit chamber designed for general use in place of the conventional grit settling troughs at sewage disposal plants has been introduced by The Dorr Co., New York. Its name, "Dorr Detritor," has been taken from the word "detritus," which is usually used to refer to the inorganics in sewage. This machine, it is stated, performs all the functions of the grit settling channels and in addition automatically collect and wash the grit, delivering it finally in a clean, dewatered condition to a suitable receptacle.

The plan and elevation views of a typical detritor installation are shown in Fig. 1. It will be noted that the detritor is located directly after the bar screen and consists essentially of four chief parts—a grit collecting tank, a collecting mechanism, a grit cleaning channel and a cleaning mechanism.

The collecting tank (Fig. 2) is square and shallow, the sewage entering along one side and being straightened out in parallel lines by a series of adjustable guide vanes or deflectors equally spaced along the influent side. The purpose of the collecting tank is to reduce the velocity of the incoming sewage to such an extent that practically all of the particles of grit of a predetermined size may settle out within the bounds of the tank. The sewage passes out of the tank across a weir which extends along the effluent side.

The collecting mechanism, a modification of the Dorr traction clarifier, consists of a combination of radial arms fitted with plow blades and an oscillating truss to which plow blades are attached. The radial arms sweep the area of the bottom bounded by a circle inscribed within the square tank, while the oscillating truss sweeps, in addition, the corners of the tank which are not reached by the radial arms. The mechanism is supported by a roller-mounted table on a central column. The oscillating truss, which is free to slide radially on the table, is attached at its outer end to a motor-driven carriage which runs on a rail on the tank top and drives the entire collecting mechanism. The plow blades move the grit outward toward the tank sides, where it is picked up by the buckets on the ends of the radial arms and deposited in the grit chute.

The chute discharges the grit into the narrow, rectangular inclined cleaning channel (Fig. 3) which extends from a point well below the water level at its lower end tor a point above water and adjacent to the grit container at its upper end. The cleaning mechanism has a reciprocating motion, the rakes

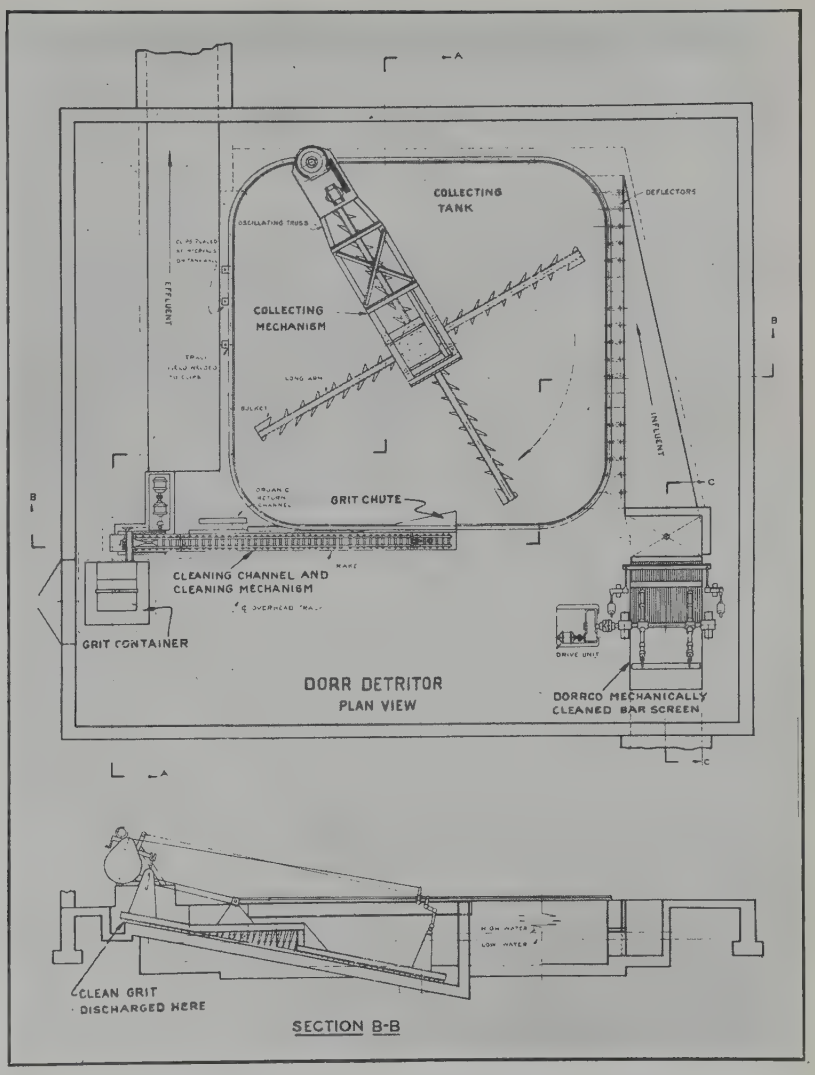

Fig. 1—Plan and Elevation of a Typical Dorr Detritor Installation

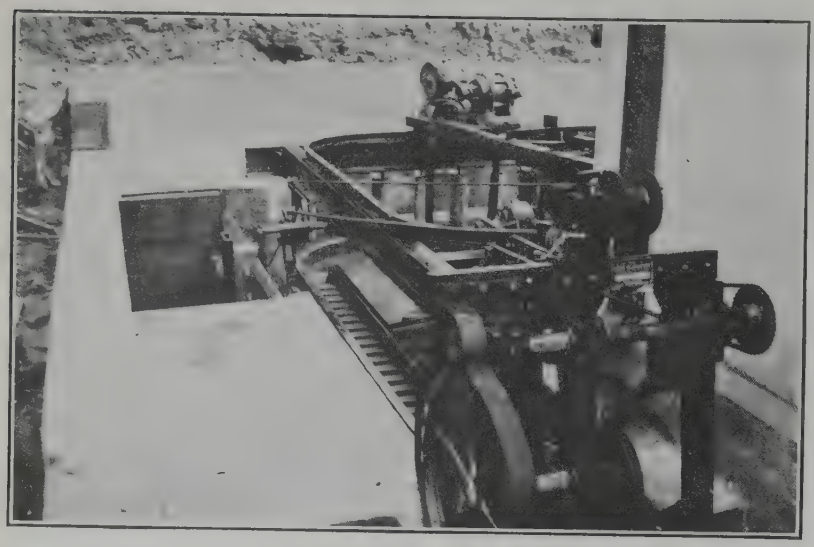

Fig. 3—Cleaning Channel and Cleaning Mechanism of Dorr Detritor

just clearing the inclined bottom and not only advancing the grit toward the point of discharge, but also imparting to it a turning over action which releases entrained organic matter. This released organic matter is kept in suspension by the gentle selective agitation of the cleaning mechanism and flows back into the collecting tank through an organic return channel in the dividing wall. This selective agitation, a result of the rake action over the inclined bottom, is stated to be just sufficient to wash back bulky organics but not the more dense sand grains.

The washed grit is drained on the above water section of the inclined channel and discharged into a grit container in a dewatered, odorless condition. As the grit is cleaned mechanically, it is unnecessary to maintain an exact velocity of flow across the collecting tank. While it is true that a velocity less than the maximum for which the machine is designed will cause the deposition of more organic matter with the grit, these organics are automatically removed subsequently in the cleaning channed and do not affect the character of the washed grit. Accordingly, duplicate units are not generally required for the control of velocity with varying volumes of sewage.

An extended test period at the initial commercial installation of the Dorr detritor is stated to have shown that the greater part of the grit of almost any fineness could be recovered and delivered to the containers with a putrescible organic content never exceeding 10 per cent and averaging over several months not over 5 per cent. That the washing has been carried out satisfactorily is evidenced by the present condition of the grit which has been recovered by the detritor over the last nine months at this plant. The grit has been exposed to the air ever since the equipment was put into operation, and in spite of exceedingly warm weather during the first few months, it is said, no obnoxious odors have been given off and there has been no evidence of a change of character that could be considered objectionable.

Nine Municipal Radio Stations in U. S.

Out of eleven municipal radio stations in the world, nine of them are located in the United States, one in South America, and one in Europe. Among those in the United States are: WPG, Atlantic City, N. J.; WCAM, Camden, N. J.; WRR, Dallas, Tex.; KGEW, Fort Morgan, Col.; WJAX, Jacksonville, Fla.; WCOA, Pensacola, Fla.; KKP, Seattle, Wash.; WNYC, New York City.

The New York station is operated by the Department of Plant and Structures of the New York City government, having been in operation for over four years, is the veteran among municipal stations. In 1927 over 1,689 hours were employed by this station in broadcasting; 720 hours were given over to vocal and instrumental music and nearly 1,000 hours to informational and educational programs; 320 balanced programs were given, including 80 lectures on municipal problems and 384 talks upon educational subjects.

WCOA, operated by the City of Pensacola, Fla., has been in operation only about three years and has given very great returns for the $7,600 a year which constitutes its budget. The officials at Pensacola believe that they are the only station which regards its main function as that of community building, developing local talent, encouraging young and aspiring musicians and players. Aside from this feature, they, like WNYC and WCAM, broadcast weather reports. These have been highly beneficial, especially to the fishing fleets sailing out of Pensacola.

In St. Louis the radio is used by police to broadcast news of major crimes. A private line connects the microphone on the desk of the chief of police with station WIL. This is to be followed up by installation of receiving sets in all station houses, and possibly in police atuomobiles. Detroit has also used the radio for some time in the police department.

In Baltimore the mayor's office has been outfitted as a broadcasting station so that meetings of the board of estimates and the board of awards may be heard from one's easy chair at the fireside. Conferences between delegations and the mayor will also be broadcast to those interested.

Airport Is Proper Municipal Function

The airport bonds approved by the voters of Kansas City and St. Louis, Missouri, last August were held invalid by the Missouri Supreme Court because of the cities' failure to revise the registration lists as required by law. The St. Louis issue was $2,000,000, and the Kansas City issue was $1,000,000.

At the same time, however, the court held that a municipal airport was a proper municipal function, saying:

"The courts which have had occasion to consider it have, however, answered in the affirmative; and no court of last resort, so far as we are advised, has ever held to the contrary. Not only that, but the function involved is given tacit recognition in numerous statutory enactments, both State and Federal. We have no doubt of the soundness of the view which obtains.

"With respect to the public uses which each subserves they are essentially of the same character. If the ownership and maintenance of one falls within the scope of municipal government, it would seem that the other must necessarily do so. We accordingly hold that the acquisition and control of an airport is a city purpose within the purview of general constitutional law."

Airports 3 Miles from Cities.—The average distance of airports from the business centers of municipalities in the United States is about three miles, according to a study made of such facilities in 436 cities by the Aeronautics Branch of the Department of Commerce. Considerable variety prevails, however, in the individual cases, some airports being within ¼ mile of the business district, and others being as far out as 18 miles. As might be expected, the larger the city the greater is usually the distance to its airport from the downtown section. In a number of municipalities of more than 100,000 population, the average distance to the airports was found to be approximately seven miles.

Water Works Improvements on the Cost Plus Basis

How an Iowa City Solved Its Reconstruction Problem

By H. V. PEDERSEN
Manager, Water Department, Marshalltown, Ia.

FEW managing boards of water works systems either municipally or privately owned are blessed with an over supply of funds for reconstruction purposes. In fact, it is common rather than exceptional for a water works department to be continually saving its surplus funds in order to retire bonds 15 to 20 years after an improvement has been made rather than to save them for future improvements. Wherever a city or private corporation has permitted its water works system to run down to a point where it must go heavily in debt to raise funds for necessary improvements, it takes a long time to get out of debt. It seldom ever does, for as soon as one bond issue is retired, the system is again in bad shape and because of lack of funds additional bonds are issued to raise the money for the improvement. In raising funds for water works improvements the private corporation cannot of course be compared directly with a municipality, but the same reluctance to spend money for reconstruction purposes exists in either case. As a rule it is comparatively easy to secure permission from either stock holder or the general public to raise funds for extension of mains, as most people readily understand that each additional block of new water mains increases the income from water rentals. In other words, there is less objection to spending money where the increased revenue will either pay for the improvement or bring a fair rate of interest on the money invested. A bond issue will usually be approved for raising funds to increase a supply of water whenever the public fully realizes that its supply is insufficient, but to tear down an old pumping station no matter how bad its condition may be and rebuild it is quite a different matter. As long as any public building hangs together it is difficult to make a majority vote in favor of a bond issue for reconstruction purposes.

It is this reluctance on the part of the public to believe that any city property, especially a water works system, should ever wear out which has compelled water works managements in many places to put off the evil day of reconstruction as long as possible and then when something must be done to prevent disaster to seek ways and means of getting by as cheaply as possible. The mere thought of a bond issue precipitates a fight and mud begins to fly in all directions, originating in most cases from sources least informed on the subject. Working on the assumption that a small bond issue will be approved more readily by the public than a larger one, the funds if secured at all are usually insufficient and the improvement suffers accordingly. Just how one Iowa city worked out its reconstruction problem might be of some interest.

Marshalltown Reconstruction Program.—The city of Marshalltown, Ia., was compelled to rebuild an original section of its pumping station this last summer. When the Board of Water Works Trustees first took the matter up for consideration it decided that no matter in how dangerous a condition the old building might be, there was little use in asking the public to vote on a bond issue. Every member agreed that, if there was any way to raise the money without a vote of the people, it was the thing to do, as they all felt that a bond issue would be defeated. A plan was finally worked out whereby a 2 mill levy authorized by state law and already received by the water department out of city taxes was pledged as security. A total sum of $50,000 was raised for water works improvements by practically mortgaging the water works property and pledging a certain definite source of income as security. No objections were raised to this plan and the bonds were issued and turned over to a bank for safe keeping to be sold only where the money was needed, thereby saving several hundred dollars of accrued interest.

The original water works pumping station at Marshalltown was built in 1876. This portion together with a number of later additions were in very bad shape. The walls were cracking and crumbling and the metal roof was practically eaten away. After careful investigation and study of the old structure it became apparent that a floor space area of 50 ft. wide and 130 ft. long had to be completely torn down and rebuilt while keeping the pumping units and boiler room in operation.

Cost Plus Plan.—After deliberation the Board of Trustees decided not to employ an outside architect and instructed its superintendent and general manager to prepare a set of plans and specifications. While investigating the condition of the old foundations and working out desirable changes, the writer became convinced that the probability of uncertain quantities which could not be determined until after the old structure had been torn down would make it extremely difficult to estimate the cost of the improvement. It was likewise believed that a contractor could not prepare an intelligently fair bid and would of necessity increase his estimated bid to take care of uncertainties. In order to insure a good job and at the same time keep the cost within a reasonable limit it was suggested that the work be done on a cost plus basis.

At first the idea of cost plus did not appeal to the members of the water board and one member was very definite in his objections. However, after each member had gone over the prepared plans and were shown the difficulties involved and after it had been pointed out that a limit could be placed on the contractor's plus they unanimously decided that money could in all probability be saved by doing the work on a cost plus basis. A contract was accordingly drawn up to fit conditions, extracts of which are as follows:

The first party (Water Department) agrees to place orders for, buy and pay for all materials necessary for the completion of this work.

The first party agrees to pay second party at the end of each week an amount equal to the second party's weekly payroll, on presentation of an itemized payroll sheet which shall be subject to check and approval by first party's water works manager.

The second party estimates the cost of rebuilding and reconstruction as defined by the plans and specifications at $..... and agrees to tear down the old building and rebuild it and dispose of all rubbish and do all of the work necessary to complete this contract as provided by the plans under the direction of said manager and in such a manner as will not interfere with the operation of the pumping units and boiler plant on a basis of such estimated cost plus $..... for his services and the use of his tools and equipment and it is agreed by the second party that if 10 per cent of the actual cost of material furnished and paid for by first party and labor furnished by second party and paid for by first party is less than the sum last above specified, then second party shall receive and be paid as compensation only 10 per cent of the actual cost. That in any event, the amount received by second party shall not exceed the sum of $..... above specified, notwithstanding the cost of the work, is greater than the estimate of $.....

Bidders blanks were prepared and bids called for. Instead of the contractor entering a bid for the total sum for which he would do the work, he simply stated the amount which he was willing to accept for his services and use of his equipment. A definite sum would be his clear profit in spite of the cost of the job.

Bids were opened on July 6, 1928, with four local contractors bidding. The estimates of the cost of the job ranged from $13,500 to $16,500 and the contractor's compensation from $1,200 to $1,500. The Board of Trustees considered the bids and awarded the contract to the contractor who they believed to have the best equipment for doing the work and who had also had the most experience. The estimated cost of the successful contractor was $16,000 and his compensation was to be $1,275.

Active work of tearing down and re-

construction began July 24 and continued until Oct. 1, 1928. A building 50 ft. wide and 100 ft. long together with a reinforced concrete coal room 25 by 50 and 22 ft. high, steel trussed roof spaced 16 ft. 10 in. on center, cost a total of $16,756.49. The materials cost $9,263.12 and the labor furnished by the contractor amounted to $3,961.35. Five masons, six carpenters and three laborers were the maximum employees furnished by the contractor at any one time. All the rest of the labor were supplied out of the regular water works employees.

The job progressed rapidly and was completed two weeks earlier than anticipated and a first class job was done in every respect. Marshalltown now has a well built pumping station of which it can be proud, at not too excessive a price. There are times when a straight contract has its advantages and is preferable, but when it comes to reconstruction the cost plus basis certainly works. If you have a questionable job, one which involves probabilities of extra quantities and desire first class construction, then buy your own materials and guarantee the contractor a definite profit.

Acknowledgment.—The above paper was presented before the Missouri Valley Section of the American Water Works Association.

Sewage Disposal in Mexico

An Outline of Present Sanitation Conditions

By ANASTASIO GUZMAN

MEXICO is just now beginning the development of sewage treatment methods. The chief cities have been provided with sewer system for a number of years, including Mexico City, which has a complete system that has merited the praise of many foreign engineers. The design of a sewer system which would be satisfactory in Mexico City was a very hard problem because of the nature of the soil and the flatness of the earth's surface. But by careful study and an expenditure of great sums of money, a satisfactory system was installed. Health conditions in that city as in others were noticeably improved with the use of sanitary sewer system.

Sanitation in Small Municipalities.—At present officials in many of the small cities and towns have become interested in the subject and the municipal governments have begun the preliminary work. Since most of the states are falling into line, we can say that the first part of our sanitary engineering problems is solved.

The above applies only to the building of sewer systems. With regard to treatment plants, we cannot say so much. In Mexico there is very little sewage treated. We dispose chiefly by dilution, which is the easiest method. The sewage is merely discharged without treatment into the streams which by themselves get rid of the sewage without causing any nuisance. The flow of the rivers is so great in comparison with the amount of sewage as to insure proper dilution. Of course these streams are never used for water supply purposes, but are frequently employed for irrigation. It must be remembered also that our streams are torrential, flow long distances and have many falls. In this way the sewage undergoes a natural process of purification. Our drinking water, as a rule, is derived from springs, artesian wells, and from rainfall collected in surface reservoirs, and we have always found these waters pure and good.

Combined Sewer Systems Common.—The sanitary and storm sewer systems are usually combined. In many small towns and villages, and especially those which are far from the principal cities, the use of the old primitive system of dry sewage is followed, which is bad. Some chemicals are used. In small private properties that cannot make connections with any sewer system, septic tanks are recommended. In some large factories the waste water is treated before being discharged into streams, and for such treatment small individual plants are installed. In one important city in the northern part of Mexico, there are large septic tanks, the effluent from which is used for irrigation.

Because of the many favorable natural conditions we have up to the present time been able to get along without sewage treatment, but these favorable conditions are now passed and sewage treatment is becoming indispensable. The small cities and villages are growing rapidly, the principal cities are enlarging their districts in the outskirts. In other words, the population is beginning to concentrate in cities just as in the United States. We have found, therefore, that in many places where the climate is delightful, people have crowded together until we find the water supplies being polluted. We are indeed beginning to feel a real need for adopting appropriate sewerage systems.

Conditions in Greater Part of Mexico.—Mexico City is a special case in itself, due to the great population which is growing daily, but in brief and general terms the conditions existing in the greater part of Mexico today are about as follows:

In the northern part of Mexico we have practically the same conditions as in the state of Texas; the climate, land and other circumstances closely resembling. The cities of this region are commercial and industrial. In the middle of the country and toward the western part, and in many places in the south, also, we have excellent climate without noticeable changes in temperature. There are many streams and the topography is broken—rather mountainous and rough—and from this we expect to obtain some advantage. On the coast and in the south, the climate is very warm, although the winters are very pleasant, and the changes in temperature will not give us any trouble. The principal sources of water supply are almost entirely independent of the rivers. One other factor which will help in making possible good sewer systems is the improvement in transportation and means of communication. We have a special commission on roads and highways which is now working constantly to extend good roads all over Mexico.

Although modern sanitary science is of recent development, and our problems in Mexico have arisen only recently, we have many experiences, works and studies from which to draw knowledge for future development. We hope to use some of the things which have been discovered in the United States and be able to skip over some of the mistakes made. In other words, sanitary work in Mexico can be started now upon a stable basis rather than having to go through the early stages of experimentation as has been done in the United States.

Only nine years ago did we begin to offer courses in sanitary engineering for the student of civil engineering, and these courses have been improved from year to year. We now have a curriculum which includes all that is covered in such courses in the United States and Germany. A few years ago the Board of Health of the Republic of Mexico undertook a great campaign to bring about the control of diseases, and to insure pure foods and drugs. The first meeting of the health officers of the various states in Mexico was held only last month. Through these meetings it is hoped to unify all these authorities just as you have done in Texas through the Texas Association of Sanitarians, and in the United States through the American Public Health Association. In the near future we hope to be able to establish in the various communities the necessary machinery to insure adequate protection of public health, welfare and happiness.

Acknowledgment.—The above is an abstract of a paper presented at the 6th Sanitation Short School, San Antonio, Tex.

Bond Issues for Sewerage and Water Works in Ohio.—Numerous municipalities in Ohio voted in November on bond issues for water supply and sewerage improvements. A total of $6,519,000 of bonds was authorized by 10 municipalities on water supply purposes, and a total of $2,203,000 was authorized by 8 municipalities for sewerage purposes.

Municipal Swimming Pools

Some Notes on the Water Supply Practice in the United States

By A. M. CRANE
Engineer, International Filter Co., Chicago

MUNICIPALITIES are competing with amusement parks and providing pools holding one, two and three million gallons. This is quite a draft on the municipal supply—unless refiltration be employed. The majority of wading pools do not use refiltration but are supplied with a constant flow of new water. This must mean something even in a city as large as Dallas. There they have about 20 wading pools, most of them about 30 ft. by 50 ft. in area. So the water demand is something which concerns the water works man, even if he is not called upon for advice in the planning of the pool. But in many cases he is called upon, and this is as it should be.

State Laws on Bathing in Potable Waters.—A few months ago, the writer, acting for the American Association for Promoting Hygiene and Public Baths, addressed an inquiry on this subject to the health authorities of our 53 states, territories, and island possessions and the result is given in the 1928 Journal of the Association under the title: "Promoting Pools by Prohibiting Bathing in waters Used for Domestic Purposes." This shows that actual state prohibition of bathing in domestic water supplies exists in California, Connecticut, Massachusetts and New York.

Kansas and Maine and perhaps other states have the authority, but have not enacted regulation. In Montana and probably other states, there is no specific enactment; but it is prohibited under general laws governing sanitation of surface waters. In Illinois, Louisiana, Maine, New Mexico and doubtless elsewhere, it may be, and is, prohibited by city ordinance or water company charter.

Down in Texas, a recent court decision restrained the use of a swimming pool in the Navasota River because it emptied into and polluted the lake of water impounded for domestic use by the city of Grosbeck. The California State Board of Health's swimming pool rules expressly state: "Disposal of swimming pool water can not be into a drinking water supply." But, on March 23, 1927, New Jersey set a horrible example by nullifying a regulation of the state department of health and enacting a statute specifically granting the right to bathe in any of the fresh waters of the state. This statute reads:

"It shall be lawful to bathe or swim in any of the fresh waters of this state, provided, that in so doing no trespassing be committed."

Of course this is all part of the broad subject of stream pollution; but while seeking to prevent contamination by sewage and industrial wastes, it will be well to remember that excretions from one typhoid patient might start a first class epidemic.

Now, if we can't bathe in the river or the reservoir—and we shouldn't bathe in the river or the reservoir—then we must have pools. And as the cry is not only for more pools, but for bigger and better pools—the whole subject is of vital interest to the city engineer and water superintendent.

Earlier Pools in U. S.—The earliest pools in this country were merely enclosures in the rivers. Then scows were used. In 1915 New York added a refinement by making its floating baths watertight—so as to prevent seepage, and supplied them with water from the city mains.

Indoor public baths came into use in Philadelphia in the eighties. In these, the pool area was not roofed. Consequently they could not be used in cold weather.

According to the late Dr. Simon Baruch, who is credited with being the founder of the public bath movement in the United States, in 1900 there were only 67 public pools in this country.

In 1913, the writer located only 540 pools in the whole United States. Of these 250 reported their dimensions. They ranged from 10 ft. by 20 ft. to 65 ft. by 140 ft.

The popularity of the pool has grown to such an extent that the first class ocean liner is incomplete without one. Right at this moment the United States shipping board is installing them on the former German ships "Monticello" and "Mount Vernon."

In the U. S. army, 59 establishments have pools—the largest entirely artificial one being 55 ft. by 169 ft. at Camp Harry J. Jones, Arizona.

It is the increasing size of the present-day pool and the state requirements as to water supply that makes the subject of particular interest to the waterworks man.

While 15 years ago a 65 ft. by 140 ft. pool was considered a large one, to-day the pools in our parks are rapidly approaching those of ancient Rome.

Increase in Municipal Pools.—Today cities are vying with amusement parks in building artificial pools which would take the entire output of a small town water works.

For example: The pool which is to be built for Elizabeth, N. J., will be nearly as large as Magner's Pool at Rye, N. Y., which holds 502,000 gal.; and the municipal pool at Estherville, Iowa, holding 375,000 gal. is nearly in this class. East Cleveland's municipal pool, holding 500,000 gal., is almost in the class of the nearby Idora Amusement Park pool at Youngstown, Ohio, which holds 740,000 gal. There are several other municipal pools now being planned which will run as large or larger than Chester Amusement Park at Cincinnati, which has a capacity of nearly 1½ million gallons.

In 1915 the American Association for Promoting Hygiene and Public Baths adopted suggested standards for swimming pools, including one reading as follows:

"Unless there is a constantly inflowing stream of absolutely pure, clear, colorless, fresh water, this condition should be approximated by filtration, refiltration and disinfection."

State Regulation of Swimming Pools.—At that time only one state—Louisiana—had any regulations and they did not go into details of the water supply; but now 27 states have definite and arbitrary regulations and 21 states require that plans must be submitted, or a permit secured, or the pool registered with, or reports made to the state board or department of health.

There has been a wide divergence in the state regulations but they are becoming more uniform since the promulgation of the report of the joint committee on bathing places of the American Public Health Association and the conference of state sanitary engineers.

Thirteen states now specify a definite degree of bacterial purity. Of late the tendency has been to stipulate the results, rather than to specify the means thereto.

New Mexico is a good example of this. Formerly they required 800 to 2,000 gals. per bather; now they do not specify any quantity of water but limit the bacteria content to the U. S. treasury department standards for drinking water. But several states still require a definite quantity. California wants 1,000 gals. of new water for each bather in "fill and draw" pools, to which they and other authorities are opposed. (California recommends circulation and refiltration daily.) Kansas requires and South Dakota recommends—1,000 gals. for each 15 persons using the pool during any period of time. This is equal to 66 2-3 gals. per bather. Virginia cut down its former recommendation of 500 to 800 gals. to 100 gals. per bather, and is now being guided by the joint committee's report. The "suggestions" of Georgia name 600 gals. per bather as the desirable quantity.

For "fill and draw" pools, Arkansas, Florida, Mississippi, Tennessee, Washington and Wyoming are satisfied with the "weekly bathing load of 20 in." (equal to 50 gals. per bather), suggested by the joint committee, but "prefer" a constant flow of new or refiltered water equal to "400 gals. per person per day considered on an average daily attendance." Oklahoma absolutely requires 400 gals. per bather both for "fill and draw" pools and those where refiltration is employed.

Use of Refiltered Water.—Of course if the demands either as to quantity of water or degree of purity had to be

met by a constant flow of water from the city mains, there would be fewer pools.

But refiltration makes it possible to use the initial supply (with a daily "make-up") for weeks or months without emptying the pool. The writer's survey in 1913 disclosed only 54 out of 272 pools employing refiltration. Today refiltration is universal. There may be a few city fathers who can't see why they should spend money for filters for the park pool just after they have paid for a city filtration plant; but they are getting fewer every day. When refiltration was first practiced—about 20 years ago, it was chiefly in indoor pools and to conserve the water and heat. Today, health is the primary reason for refiltration—although without it, the cost of operation would prohibit pools in many places.

Refiltration not only conserves water and heat, but keeps down the contamination of the water by the bathers.

Diseases from Unfiltered Pools.—In 1915 Dr. Manheimer cited 19 authorities who had reported venereal, ocular, aural or intestinal diseases contracted from swimming in polluted water. In 1929, Professor Hinman, one of the foremost investigators of the subject, tabulated the diseases as follows:

1. Intestinal infections, such as typhoid fever, dysentary, etc.
2. Infections of the respiratory system such as gripps, colds, sore throat and sinus infections.
3. Eye and ear infections, such as conjunctivitis, rhinitis, and ethmoiditis.
4. Gonorrheal infections.
5. Skin infections.

Reports of infections contracted by children in wading pools and tests showing highly contaminated water, have impelled the American Association for Promoting Hygiene and Public Baths to undertake an investigation of this subject. So far we have received reports from 87 pools and these show that the average area is as large as the swimming pools reported in our survey of 15 years ago, although the average maximum depth is necessarily lower, this being 20 in.

In the majority of these wading pools it seems as if there is a constant inflow while the pool is in use.

Out of 54 of these pools, 30 of them refill daily, two, twice a day, three, four times a week, six, three times a week, six, twice a week, and seven, once a week.

It remains to be seen whether or not the A. P. H. A. and state sanitary engineers will take cognizance of the situation; but a number of the members of both organizations have expressed themselves in agreement with our feeling that authorities should ordain the same standards of purity for wading pools as for other "Bathing Places."

Of course it would be quite unnecessary to go into structural details which should be left to the architect or engineer; and it would be impracticable and prevent an increase in wading pools to require a pre-cleaning shower; but the lack of a "scrub" and the fact that many of the youngsters wear dirty clothes which are immersed in the pool, making imperative a constant flow of pure water.

The sum total of this whole argument is:

1. The increasing size and growing number of swimming pools and wading pools demand the interest of waterworks men.

2. So far as purity of water supply is concerned, both swimming pools and wading pools should be considered on the same basis.

3. Unless there is a constant inflow of pure new water, this should be approximated by refiltration and disinfection.

Use of Dye in Underground Leakage Surveys

A dye test method of locating underground leakage has been used with excellent results by the Underground Leakage Section of the Department of Public Works of Chicago. The method was developed for use where the mains are at extreme depths below the street and where the mains lie in water bearing soil. This condition exists particularly in South Chicago where many mains are at depths varying from 11 to 12 feet below the present street level. Mains in this section of the city were laid in marshy ground 40 to 50 years ago and the street grades were gradually raised until the water mains and services are at the depths stated above in soil which is constantly filled with water. The mains and service pipes up to the stopcock are invariably covered with water or are water bound, in which condition very little or no sound is transmitted by the leaking water. The locating of underground leaks under such conditions is almost impossible when ordinary methods are resorted to. The dye method of testing to determine the location of leaks under such conditions was developed by William B. Weldon and Leonard Mauel who have been in direct charge of the field parties on this work. The method may be briefly described as follows:

After a section of main has been isolated and the service pipes shut off, when leakage is indicated, a vegetable dye (fuchsine) which colors the water red is passed into the pipe at the location of the by-passed valve. This dye is contained in a tank under sufficient pressure so that it can be forced into the main under test. The rate in feet per second at which the dye colored water in the main is moving can be determined by considering the cross section of the main and the volume of water being recorded by the master meter. After this rate has been determined the service pipe is disconnected at the first house meter and the water is drawn off in a volume equal to the contents of the service pipe. If the dye has reached this point in the computed time, the water is shut off on the service pipe and the next service pipe opened and similarly tested. When a point is reached where the dye does not come through the service pipe in the computed time, it is necessary to draw off the uncolored water until the dye-colored water appears. The water thus drawn off is measured and when the volume of the same is divided by the area of the cross section of the pipe the distance from the service pipe under test back to the point of the leak is determined. In this way the location of an underground leak can be determined without the use of sound instruments or without excavating at random. This method has been used very successfully in the South Chicago district.

The dye test method was used in 45 sections and on some of these the test had to be repeated two or three times because of distributed leaks. In 25 of the 45 sections the leakage located amounted to 583,911 g.p.d. In 20 other sections 285,164 g.p.d. was located.

Motor Vehicle Operation by Water and Power Commissioners of Los Angeles.—According to the 27th annual report of the Board of Water and Power Commissioners of Los Angeles, Calif., for the fiscal year ending June 30 last, the board had a fleet of 512 motor vehicles, consisting of 175 trucks, 143 work cars and 194 automobiles. In addition there were 28 trailers and 18 pieces of equipment mounted on trucks, such as air compressors, hoists, pumps, electric welders and fuel tanks; also 152 pieces of construction equipment of various kinds used in the construction and operation of the works. The total mileage run by the fleet during the past year was 5,313,365 miles or 10,377.6 car miles. Trucks made a total of 1,362,912 miles, which is an average of 7,447.6 miles per truck, with the total miles run by the automobiles and work cars was 3,950,453 miles, which is equivalent to 11,253.5 miles per car. The average cost per car mile for the automobiles operated last year was 5.7 cts. and for the trucks 18.5 cts., as compared with a 6-year mean of 5.9 cts. and 18.8 cts. respectively. The total miles run this fiscal year exceeds last year by 564,946 miles.

Airport Survey in Michigan.—The League of Michigan Municipalities is undertaking an airport survey of the state for the purpose of ascertaining the number of airports, stages of development, method of financing, management and progress where development has been urged.

Water Works Records

How Detroit Keeps Records of Its Distribution System

By CLARENCE W. WRIGHT
Assistant Civil Engineer, Department of Water Supply, Detroit, Mich.

ONE of the purposes of the engineering bureau is to procure and preserve accurate records of all work done in connection with the distribution system. This system consists of all pipes used for the carrying of water from the pumping station to the streets or alleys adjoining each home or commercial enterprise. Orders to lay pipe are all numbered and divided into four classes, "A," "B," "C" and "D."

The "A" jobs are those recommended by the department and consists of the laying of mains above 16 in., replacements, the lowering of mains where necessary in streets to be paved or resurfaced, and mains laid to furnish better fire protection.

The Pipe Laying Budget.—At the time the annual budget is made up, a list is prepared of all mains 16 in. and larger which it is desired to lay during the following fiscal year. When the budget is finally approved, a revision of this list is made, based upon the amount of money available for large mains. This list is then submitted to the board for approval. Following this, plans and profiles are prepared, and the lines are laid as soon as practicable.

At the beginning of each year the department of public works publishes a list of streets and alleys it intends to pave or resurface during the following year. An investigation is immediately made to determine what work must be done in these streets during the coming year. It has been the policy of the department to replace all 4-in. mains with 8-in. or larger. As soon as notice is received of the intention of the department of public works to pave or resurface a street in which there is a 4-in. main, this main is immediately ordered killed and a larger main is ordered laid to replace it. The old mains are removed wherever convenient. Otherwise, the service connections are transferred to the new mains, the connections to other mains are cut off and the mains are abandoned. The depth of service mains in streets to be resurfaced is measured at each gate, or wherever opportunity affords. In case such mains are found to be so shallow that service connections are liable to freeze, the main is either lowered or replaced, or the service connections are lowered.

Work Preliminary to Paving.—Before paving contracts are let by the department of public works, photostat copies of the plans and profiles are sent to the department. Depths are taken by the maintenance division on all water pipes in the streets. The profiles are then returned to the engineering division and the pipes ordered lowered wherever the future grade of the street will give the pipe less than 4½ ft. of cover. It has been necessary to lower considerable pipe which was originally laid in territory outside the city limits, and which has since been annexed to the city. It is for this reason that the inspection of pipe laid outside the present corporate limits, but connected to the Detroit system, is so rigid. Grades are given on all pipe lines 24 in. and larger and wherever necessary on lowering jobs. The remainder of the pipe is laid on an even grade with a minimum cover of 5 ft. in paved streets and 6 ft. in unpaved streets. Street lines are located for the foreman wherever necessary, but this is required only in undeveloped subdivisions.

Much of the water pipe laid in the various sections before annexation to Detroit was of insufficient size and was placed in the alleys or easements. Hydrants could not be placed in locations which would provide adequate fire protection. These mains have therefore been replaced by larger pipes laid in the streets. These new mains have been ordered by forced petition by the Board of Water Commissioners.

All pipe laying jobs ordered upon petition are known as "B" jobs.

Laying Extensions.—If a man owns a lot located inside the city limits and desires water, he need only come to the office of the department of water supply, sign a petition requesting that pipe be laid to supply his lot, pay 75 ct. per foot of frontage served, and the department will, at its earliest convenience, lay a main past the front of his lot. This work is done under city ordinance. As soon as a petition is received, a plan is made showing the pipe it will be necessary to lay in order to supply the petitioner with water. This plan shows the size of pipe to be laid, the location in the street of the proposed line, and the location and size of all specials and gates. The scale used, 1 in. equals 100 ft., is sufficiently large to give this information since most extensions are made in the outlying districts.

A resolution is then passed by the board of water commissioners and the common council declaring the main necessary and ordering the work done.

An assessment roll is next prepared, assessing 75 ct. per foot of frontage against each lot which may obtain water from the new main. No charge is made where a main runs past the side of a lot, but acreage is assessed on all frontages.

An advertisement is published five times in a daily newspaper stating that the roll will be in the assessors' office for 12 days from date of the first publication.

The roll goes to the common council which either confirms it or orders it revised. If confirmed, the assessment becomes a lien against the property assessed and the roll goes to the city treasurer for collection.

The treasurer then advertises the roll in two newspapers once each week for three successive weeks, that the assessments are payable within 60 days from the first notice. Bills are also mailed to each person on the roll. If the assessment is not paid in 60 days, a penalty of 1 per cent per month is added for six months in addition to six per cent interest.

The real estate may then be sold for unpaid assessments in the same manner as in the case of sales for non-payment of general taxes.

After the water pipe is laid no owner is allowed to have a service until the assessment against his lot is paid.

Work Beyond City Limits.—The "C" jobs are beyond the city limits. If a subdivision or village outside of Detroit desires to lay mains in which Detroit water is to be furnished, they must first present a pipe layout for approval as to size of main and location of gate valves. When this is approved and an agreement is signed, and an inspection fee of 3½ct. per foot is paid, the contractor may begin work. An inspector is placed on the job who protects this department as to workmanship and depth of pipe.

All jobs where the cost of the work is billed to outside organizations are known as "D" jobs. This includes the changing of water mains for the construction of sewers, grade separations, etc.

Sketches are made in the field of all pipe laid, lowered or discontinued. Dietzgen's engineers' field book No. 400 is used for this purpose. Loose-leaf field books were tried for a time, the sheets being later bound, but it was found that sheets were either mislaid or destroyed, and valuable records were lost. It was also found that there was a tendency to merely make notes or temporary sketches in the field and to make the permanent sketches in the office. The final sketches so made were a little neater, but they were much more inaccurate and there was considerable danger on an engineer trusting to his memory to retain details. Frequently no sketches were made of small jobs because the sketchers had mixed these notes with notes of larger jobs.

By making his sketches on the job the engineer can see immediately what measurements are necessary, and he can get them at once. There is no danger of his forgetting such things as which way the pipe swings or where the swing begins and ends. Small matters, such as whether gates are in wells or boxes, are not missed. The engineer is required to check the measured length of the line against the foreman's pipe record, and to check the specials sketched against those shown on the pipe record. In this way many errors are eliminated as differences between the sketch and the pipe record can be checked by looking at the pipe in the ground. It has been the plan of the engineering bureau to have the sketch-

ers see all the pipe in the ground. This may mean that the sketcher will have to make several extra trips. He can, however, sketch the work as it progresses and thus avoid errors which would creep in were he to wait until the completion of the job before making any sketches.

Recording Pipe Lines, Etc.—The bureau keeps engineering records of pipe laid outside of the city but connected with the Detroit system, just as it does for its own pipe. This applies to villages receiving water from Detroit as well as to outlying subdivisions. All records of pipe laid are filed under north and south streets. Under each north and south street is further indexed all intersecting streets. Two important streets, Gratiot and Grand River Aves., which run at an angle with true north, are treated as north and south streets. Three sets of maps are used for recording pipe lines: intersection maps, section maps and distribution maps.

A map is made on tracing cloth of each street intersection, to a scale of 1 in. equals 16 ft. Alleys in which there are pipe lines are shown on the intersection of the street nearest. On these maps are shown all the details of the piping system. All locations are given from the property lines. Curbs are shown but sidewalks are not. Sewers, gas lines, conduits, etc., are shown wherever the water mains intersect them. These sheets are 20x21 in. and are bound loose-leaf fashion in sets of 20 to 40 sheets. This makes readily available all information regarding location and size of mains, gates, connections, etc.

Sectional Maps.—The sectional map of the city is drawn to a scale of 1 in. equals 300 ft. The sheets are 20x21 in. and are bound loose-leaf fashion. On this map is posted all distribution pipe. All gates, blow-offs and private sleeve and valve connections, hydrants and cisterns are also indicated. Solid lines only are used to indicate pipe lines, the width of the lines indicating approximately the size of the main. The sizes of all mains and many of their locations are also marked on them. The first of every year approximately 100 blue print copies are made and one copy is given to every foreman, leak investigator and tapper.

The city of Detroit and the surrounding territory is also shown on a map which is drawn to a scale of 1 in. equals 1,000 ft. This map is made up of 15 sections and is known as a distribution map. On it is shown all mains and gate valves and their sizes.

The sources of information as to the sizes of lots, widths of streets, names of subdivisions, etc., are the topographical maps, copies of recorded plats and real estate atlases.

The topographical maps are prepared by the city engineer's office and now cover the whole city. They are printed on cloth to a scale of 1 in. equals 200 ft.

Photostat copies of recorded plates are secured from the tract index office of Wayne County.

The increase in area of the city of Detroit has been 56.7 square miles in the last six years. During the same period the water system has grown from 1,647 miles to 3,401 miles, or an increase of 1,754 miles. This includes all areas furnished with Detroit water.

This increase in the volume of work has temporarily resulted in our permament records not being up-to-date. The relief from additional annexations within the last two years has lessened the demand for new mains and the engineering bureau is now in a position to make a gain in its permanent records.

Acknowledgment.—The foregoing is taken from a descriptive survey of the Department of Water Supply of Detroit, Mich., issued Oct. 1 by the Board of Water Commissioners.

Missouri Conference on Water Purification

The Missouri Conference on Water Purification held its fourth and most successful meeting at Hannibal, Nov. 15, 16 and 17. Interest in the program was evinced by the attendance of 75 members and guests and by the lively discussions which followed the presentation of all papers.

The Missouri Conference on Water Purification was organized by the State Board of Health for the purpose of providing an opportunity for those in charge of municipal water purification to become more closely affiliated and better qualified for their work. The hopes for the service which this organization could render in the production of safer municipal water supplies and better protection of the public health have been amply realized. Largely through the efforts of the organization, a marked improvement has been made in the operation of water purification plants in the state and an increased sense of responsibility has been developed among those in charge of the production of a commodity which is of the utmost importance to the public health.

Several changes were made in the constitution of the Conference. The name was changed to Missouri Water and Sewerage Conference in order to indicate that the present scope of interest included municipal sewerage as well as water systems. Provision was also made for affiliation of the Conference with the Federation of Sewage Works Associations.

The time and place of next year's meeting will be determined by the incoming Executive Committee. Following are the officers elected for the ensuing year:

Chairman—C. E. Heflin, Water Commissioner, Cameron, Mo.

Vice-Chairman—S. J. Duncan, Superintendent, Waterworks, Moberly, Mo.

Secretary-Treasurer—H. D. Peters, Assistant Engineer, State Board of Health of Missouri.

Executive Committee—W. V. Weir, Assistant Manager, St. Louis County Water Company, University City, Mo.; E. E. Wolfe, City Chemist, Hannibal, Mo.; W. P. Britain, Superintendent, Waterworks, West Plains, Mo.; J. N. Wells, Superintendent, Joplin Water Works Company, Joplin, Mo.

Index for A. S. T. M. Standards

The American Society for Testing materials, 1315 Spruce St., Philadelphia, Pa., has issued a pamphlet containing an index to all A. S. T. M. standards and tentative standards. The number of these standards and tentative standards has increased to such a degree (548 in all) that a complete index was deemed desirable and accordingly the present index was compiled in addition to the individual indexes appearing in the society's books of standards. The index will be a valuable aid in ascertaining whether the A. S. T. M. has prepared a specification or test covering a given material, and if so, its title and serial designation and where it is published in its lowest form. The index now becomes a permanent annual publication of the society.

Water Consumption in Los Angeles, Calif.—The mean water consumption in the city of Los Angeles, Calif., for the fiscal year ending June 30, 1928, was 323.3 second feet, of which 98.2 second feet was for irrigation purposes. The mean summer consumption was 428.8 second feet, of which 254.5 was domestic. The mean winter consumption was 221.9 second feet, 195.8 being domestic. The peak consumption was in July, 1927, the total being 542 second feet, of which 282 was domestic.

Traffic Survey for New York City.—New York City has engaged the services of Day & Zimmermann to make a survey of traffic congestion in the five boroughs of the city, including commuter traffic to New Jersey. It is intended that the studies made by private organizations, such as the Regional Plan of New York, and all data gathered by such city departments as police, and plant and structures shall be used. Rapid transit problems are not included in the traffic study.

County Parks Show Profit.—According to the report of the county park commission, parks in Westchester County, New York, made a profit for the county of approximately $175,000, and in addition created wealth for the county through assessed valuations amounting to $125,000,000 during the past year.

Municipal News and Water Works

Vol. LXXVI MARCH, 1929 No. 3

The Experimental Filtration Plant of Chicago, Ill.

What It Is and What It Is Doing

By JOHN R. BAYLIS

Physical Chemist, Bureau of Engineering, Chicago, Ill.

The Department of Public Works of the city of Chicago, Ill., placed in operation last April an experimental filtration plant, which is probably the largest and best equipped installation ever constructed for studying water purification problems. The plant cost approximately $150,000 and the operating expenses will run around $35,000 annually. On the basis of the results obtained larger plants for handling the entire water supply will be designed. The accompanying interesting description of this plant and outline of the experiments now under way and contemplated were given in a paper presented Jan. 23 at the 44th annual meeting of the Illinois Society of Engineers.

WATER treatment has made such rapid advances within the past 30 years that some may wonder if there still remain unsolved problems justifying a city in making an expenditure of a quarter of a million dollars for research work on water purification. If we should gather together all the leading filtration engineers and filtration chemists to formulate a plan, based on current practice, for filtering Chicago's water, there would be nearly as many ideas on various details of the work as there are individuals. Many of these ideas would work; that is, water of a good quality could be produced, but some of the ideas would be more economical to construct or operate than others. It is not a question whether the water may or may not be purified, for we all know that it can be. The major problem is to find the cheapest and most efficient treatment for Chicago. In other words, the various opinions will be taken and tested under conditions that will give specific information as to their feasibility.

New Ideas to Be Tried.—No one need expect startling revelations, or the perfection of methods that will revolutionize water treatment, yet many new ideas will be tried, and out of this may come a few things that will be of aid in the production of purer and more palatable water. A very rigid standard of quality has been adopted as our aim and any treatment that does not produce water that comes up to the standard will be regarded as inferior. The water must be free from objectionable tastes and odors at all times, it must be safe bacterially by averaging not over one-tenth the number of B. coli allowed by the Government Standard for Drinking Water on Common Carriers, and the turbidity must average not over 0.2. It is hoped that the design and type of treatment to produce

these results will involve nothing unusual, especially as some of the better operated plants throughout the country are now equaling this standard and Chicago does not want a water inferior to that of other cities.

Opinions differ as to the merits of the several kinds of treatments that may be used and the different kinds of equipment found in the various filtration plants. In many instances there may be considerable modification of the design of a plant or a change in the method of treatment without affecting the quality of the water produced. For such cases economies of construction and operation should receive the greatest consideration. The efficiencies of the several treatments in common practice and the relative merits of the various kinds of equipment will be studied thoroughly. When it is understood that the experimental plant was constructed more for this purpose than to try to develop new methods of treatment, the reason for the elaborate layout becomes apparent. The experiments must be conducted in a manner that will leave no doubt as to the findings.

General Description of the Plant.—The experimental plant is housed in a frame building with stucco on the outside. The grounds around the plant have been graded and beautified, and this together with the attractive exterior of the building gives a very nice appearance. Being located in a fashionable residential section it is evident that the structure should be one that does not detract from the surroundings.

The main parts of the plant are constructed of reinforced concrete or steel, following to a large extent customary filtration practice in the materials used; that is, the main parts of the plant are constructed of materials as durable as though it was to be operated indefinitely. With the exception of a few small tanks, all basins and filters are constructed of reinforced concrete or steel. Division walls in the mixing basins and settling basins are of wood, but the wooden walls hold practically no head of water. It might be said that the mixing basins are of wood submerged in a concrete tank. This allows the use of light materials for construction, and being submerged, it is protected from decay. Considering labor

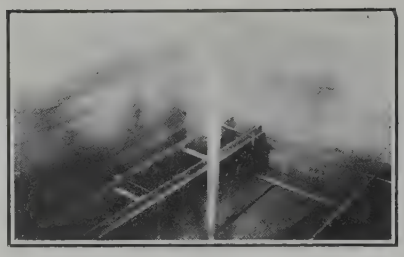

Fig. 2—Surface Wash in Filter No. 2

conditions in Chicago very little if any more will be expended on the structure by making most of it permanent than would have been necessary to keep wooden equipment in operating condition. It also gives a feeling that the experiments are being conducted under conditions so near actual practice that the results cannot be questioned. The layout of the plant is shown in Fig. 1.

The thought foremost in mind when designing the plant was to be able to conduct experiments with only one variable, that is, the variable would be the thing being tested. If rates of filtration are being tested, then every thing else should be the same, except the rates of filtration. The water should be all the same through every process until it reaches the filters, where it will divide and go to the several filter units set to operate at various rates. The range of filtration rates desired is obtained by having a number of units operating at the same time rather than operating one or two units over a period of time at certain rates and then changing the rates over another period of time. This method of conducting experiments will be followed for tests on the size of sand, kind of sand, depth of sand, time of mixing, time of settling, and probably other tests.

The main features of the plant may be summarized as follows:

1. A balancing tank for keeping a uniform head of raw water on the control valves.

2. Four chemical solution tanks and one dry feed machine. With this equipment three kinds of chemicals may be handled at the same time.

3. Three mixing basins. One where the flow is through horizontal conduits, one where the flow is through vertical conduits, and mechanical agitation.

4. Four settling basins, which will be operated usually as two basins with two compartments each.

5. One small settling tank with five compartments.

6. Twelve filters. Two of the filters have a sand surface area of 100 sq. ft. each and the other ten have a sand surface of 10 sq. ft. each.

7. Two clear water reservoirs.

8. One wash water tank.

9. Two wash water pumps.

10. Carbon dioxide generating plant.

11. Two chlorinating machines.

12. Chemical laboratory.

13. Bacteriological laboratory.

Mixing Basins.—It was thought best to construct three kinds of mixing basins, but when one considers the various kinds of experiments that are to be conducted and the variations necessary in the flow of water, it becomes evident that the mechanical mixing basin will have to be used for most of the experiments. Every time the rate of flow is changed in channels or baffled basins it produces a change in the agitation of the water, whereas the violence of the agitation in the mechanical mixing basin is independent of the rate of flow through the basin. It is true the water passes through in a shorter time when the rate is high, but with eight points where the water may be taken off it need not pass through the entire basin when the flow is low. The mechanical basin is divided so that one-half of it may be used for one treatment and the other half for another treatment. Interchangeable gears allow the speed of the stirrers to be varied over quite a wide range.

The horizontal and vertical mixing basins are made to give a water velocity about equal to that of customary practice in horizontal baffled basins and in over-and-under basins. These basins will be compared with the mechanical basin, and will be used for a few experiments. Because filtered water is being given away, there will be times when one of these basins will be used for treating a supply of drinking water while the mechanical basin is being used for an experiment where the quality of the water for drinking purposes may be in doubt, otherwise they will be used only for certain specific experiments. One of the worst things that

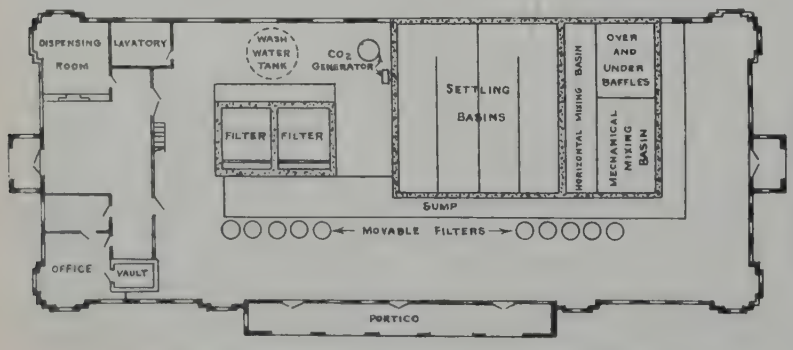

Fig. 1—Plan of Experimental Filtration Plant of the City of Chicago

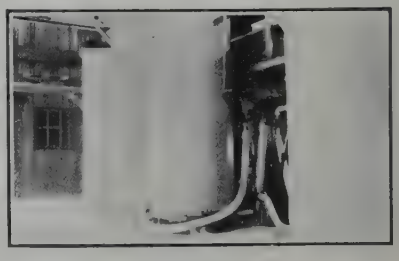

Fig. 3—Small Filter Mounted on Movable Platforms

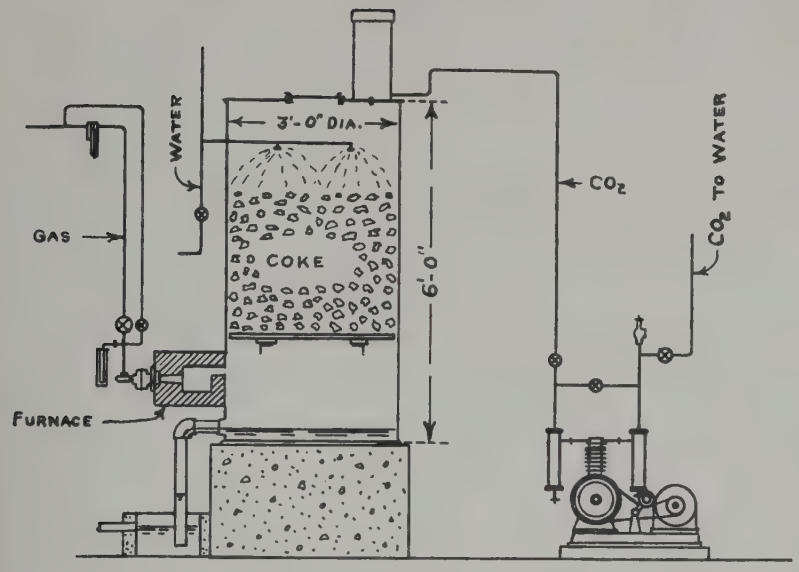

Fig. 4—Carbon Dioxide Plant

might occur in its effect upon the public would be to give away water that was not satisfactory in every respect, and chances cannot be taken with the drinking water. If only experiments that produced an excellent quality of water were conducted the desired information might not be gained, for it is important to know just how much a treatment may be varied without affecting the quality of the water and it is necessary to extend a few experiments to the point where satisfactory water is not produced.

The horizontal basin is a series of horizontal conduits, 50 altogether, about 10 in. square and 30 ft. in length. This is 1,500 ft. of conduit. With a velocity of 1 ft. per second it will take the water 25 minutes to pass through the entire mixing basin. For this velocity each return of the water to one end requires 1 minute and with the same velocity the full volume of the water may be taken off after running in the conduits 1, 3, 5, 10, 15, 20 and 25 minutes. Take-offs for the small filters are provided at 1, 2, 3, 4, 5, 7, 10, 12, 15, 17, 20, 22 and 25 minutes mixing when the velocity is as stated. Changing the velocity will of course change the time of mixing for the take-offs, but there are a sufficient number to give the desired information on any kind of an experiment that may be conducted.

The vertical conduits, or over-and-under basin, are very much like the horizontal basin, except that the flow is upward and downward and there are more turns. There are 81 conduits, 12 in. square, and 11 ft. 3 in. long, making a total length of 911 ft. This provides for about 15.2 minutes mixing at a velocity of 1 ft. per second. Due to the large number of turns in the basin it was thought that a velocity slightly less than 1 ft. per second would do the same work as a velocity of this amount in the horizontal conduits, and this is one of the reasons for making the conduits with a little larger area than for the other basin. There also are a few less take-offs provided, but the number is great enough for any kind of experiment that may be performed. With a liberal supply of overflows and take-offs the water velocity through any part of the plant can be regulated to any desired figure. Comparing the horizontal basin with the vertical basin at a velocity of 1 ft. per second in the conduits, the take-off on the horizontal conduits at the 15-minute point is opened and the one at the same point on the vertical basin is also opened. This will mean that more water passes through the vertical conduit basin, but the excess can go to waste so that the settling basins and filters may handle the same amount of water.

Experiments having most any violence of agitation and time of mixing may be conducted with one of the three mixing basins. From this we hope to formulate some idea as to the best type of mixing basin and time of mixing for the large plant, but bearing in mind that small basins may not give an exact duplication of larger ones. To get the same violence of agitation as is produced in a large basin a certain velocity must be maintained; that is, reducing the scale of a large basin one one-hundredth or more will not answer the purpose, for the violence of the agitation would be changed to the extent of materially affecting the results. Reducing the scale, but maintaining the violence of agitation with the stirrers in the mechanical basin probably will give the same results as a large basin, and it is this type of basin that we are relying on for most of the experiments where the mixing might have an influence.

Settling Basins.—There are four settling basins, or it might be said that there are two basins with two compartments each. The compartments are 7 ft. wide, 30 ft. long, 12 ft. deep at one end and 10.5 ft. deep at the other end. It is not expected that a great deal will be learned about the design of large settling basins from these small ones, but the desired degree of settling can be determined. Careful measurements of the suspended matter settled from the water are being made; in fact, the volume of coagulated matter is measured on the water as it goes to the basins and as it leaves. Occasional tests will be made at points throughout the basins. If it is found desirable to settle out 90 per cent of the coagulated matter from the mixing basin water, or it is desired to settle

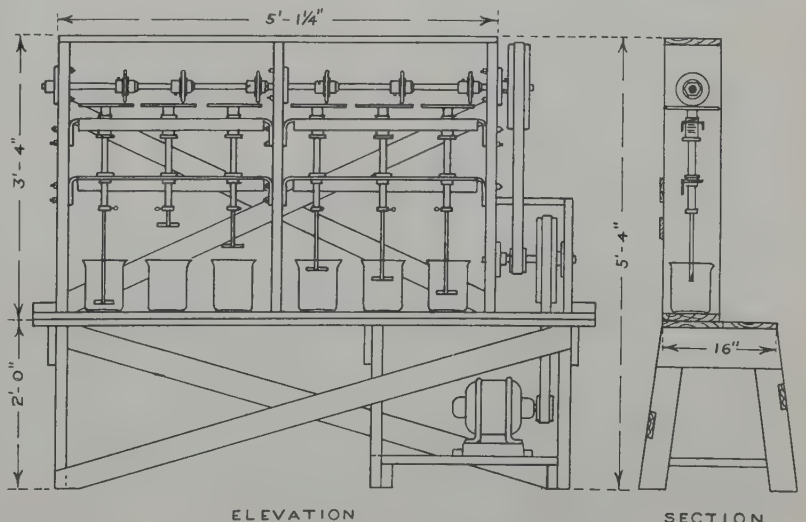

Fig. 5—Laboratory Stirring Machine

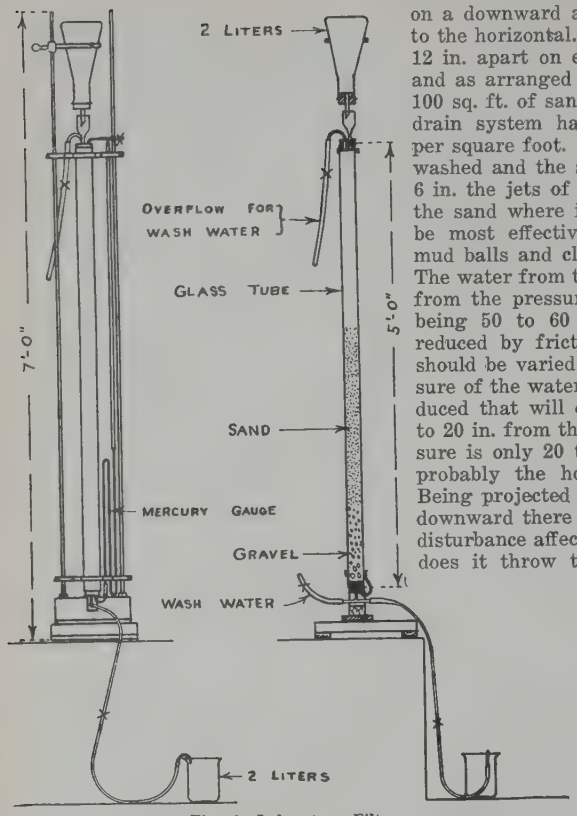

Fig. 6—Laboratory Filter

to a definite amount of coagulated matter before the water goes to the filters, more reliance will have to be placed on what is being accomplished in the large settling basins throughout the country than the results obtained in such small basins. What should be accomplish by sedimentation can be determined fairly accurately, and this will be of great aid in determining the size and shape of the large basins.

Filters.—The design of the larger filters is in accordance with standard practice. They are constructed of reinforced concrete and are similar to a large number of filters of this size throughout the country in that there is a bed of sand 24 in. thick, 13 in. of graded gravel, a system of underdrains, and filter rate controllers. The underdrain system at present is perforated pipe, 2 in. in diameter, spaced 12 in. apart on centers, and having 11/32-in. holes spaced 6 in. on centers. It is planned to remove these underdrains later and test other types. One of the filters has a marble operating table and hydraulic valves, whereas the valves on the other one are hand operated. Both filters have gauges that record and indicate both the rate flow and loss of head.

Surface Wash.—The only thing unusual about the filters is the surface wash. This is a system of ¾-in. pipes spaced 20 in. apart and located about 1 in. above the sand. The pipes have 3/16-in. holes to project jets of water on a downward angle at about 30 deg. to the horizontal. The holes are spaced 12 in. apart on each side of the pipes, and as arranged there are 96 holes for 100 sq. ft. of sand surface. The underdrain system has two 11/32-in. holes per square foot. When a filter is being washed and the sand is suspended 4 to 6 in. the jets of water are thrown into the sand where it is believed they will be most effective in breaking up the mud balls and clogged masses of sand. The water from the surface wash comes from the pressure mains, the pressure being 50 to 60 lb., but it is greatly reduced by friction losses. The holes should be varied according to the pressure of the water. A jet should be produced that will cause a disturbance 15 to 20 in. from the pipe, and if the pressure is only 20 to 25 lb. the pipes and probably the holes should be larger. Being projected at an angle of 30 deg. downward there is no possibility of the disturbance affecting the gravel, neither does it throw the sand upward more than the usual wash when as much water is being applied beneath the bed as the total amount used.

Wash water is now being applied underneath the beds in the usual manner at a rate of 19 in. vertical rise per minute and through the surface wash at the rate of 5 in. vertical rise, consequently the total wash water used is the same as if 24 in. vertical rise was being applied only underneath the beds as is customary practice. No additional water is used, but about one-fifth of it is being applied through the upper system of piping at a higher pressure than that applied beneath the bed. The upper or surface wash is turned on at the same time or in advance of the regular wash and is cut off about one-fourth minute in advance of the regular wash so that the bed will settle to a smooth uniform surface. The gentle disturbance produced in the ordinary wash is not sufficient to prevent the formation of mud balls and clogged places for many of the waters now being filtered. The surface wash will not break up clogged areas that are resting on the gravel as all large clogged areas do, but it will keep the sand so clean that the clogged areas will not start.

Most mud balls remain on or near the surface of the sand and do not greatly affect the filter beds except that sand frequently becomes embedded in the mud, causing it to sink to the gravel. This frequently starts the formation of clogged areas. Mud balls on the surface may materially affect certain kinds of experiments and it is necessary that the sand be kept clean and the surface smooth. Scraping the surface would remove some of the fine sand that is usually near the surface and would be correcting a bad condition only to allow it to get bad again, consequently it seems that some such washing device is almost an essential. Fig. 2 shows the sand surface to be free from mud balls, or clogged areas which usually occur along the side walls first. This bed had been in operation about eight months. The Lake Michigan water is not one that causes the filter beds to clog badly and this does not prove that the surface wash would keep filter beds in good condition elsewhere, yet it is believed that it will if properly installed and properly operated. The proportion of water to be applied through the surface wash may need to be greater than one-fifth where the beds clog badly.

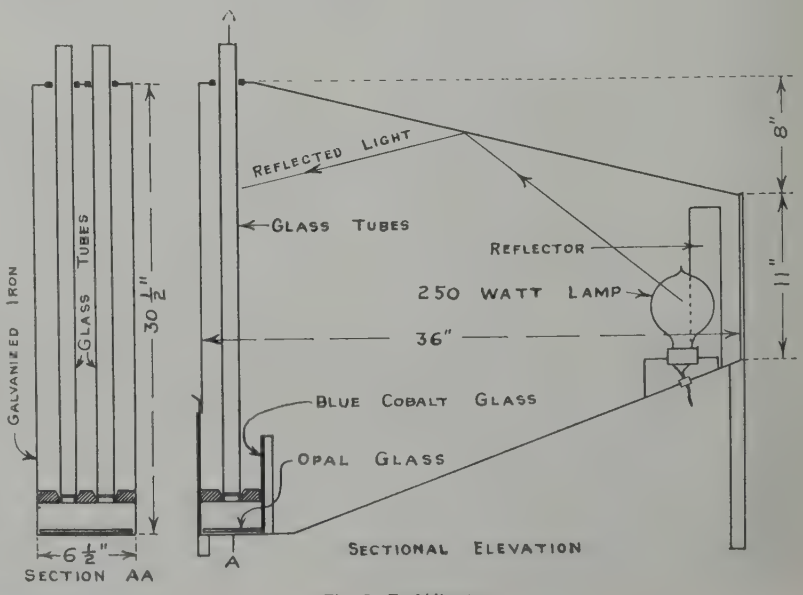

Fig. 7—Turbidimeter

Small Filters.—The small filters, which have 10 sq. ft. area each, are constructed of steel. They are set on platforms so that they may be moved from one location to another with a Barrett lift truck. The filters are provided with hose connections so that changes in the set-up may be made by the operators without having to change any piping. Some of the hose may be seen in Fig. 3, which shows several of the small filters. Where frequent changes have to be made, and union rules do not permit filter operators to do piping work, the wisdom of using hosing connections becomes apparent. There has been less than one day of work for a plumber since the plant was constructed, yet the small filters have been moved about considerably since starting operation.

The rate of flow through the small filters is set by hand, the rate being adjusted every hour. Fairly uniform control is obtained in this manner, more uniform than may be expected. Each filter has two meters, one a venturi for use in setting the rate and the other an ordinary service meter for keeping a record of the amount filtered. It is true that such an arrangement requires constant watching, but additional help is not required when the filters are being run. Having 10 units of this size hastens the completion of the experimental work, and as has been stated enables experiments to be conducted with a greater degree of accuracy than would be the case with fewer units.

Carbon Dioxide Plant.—The CO_2 used for recarbonating the water, when the treatment leaves it more alkaline than it should be for domestic uses, is obtained by burning city gas. This is not the cheapest way of producing CO_2, but it gives a constant flow which is of great importance in experimental work. The CO_2 apparatus, except the compressor, was furnished by the Flinn & Dreffein Co. This is shown in Fig. 4.

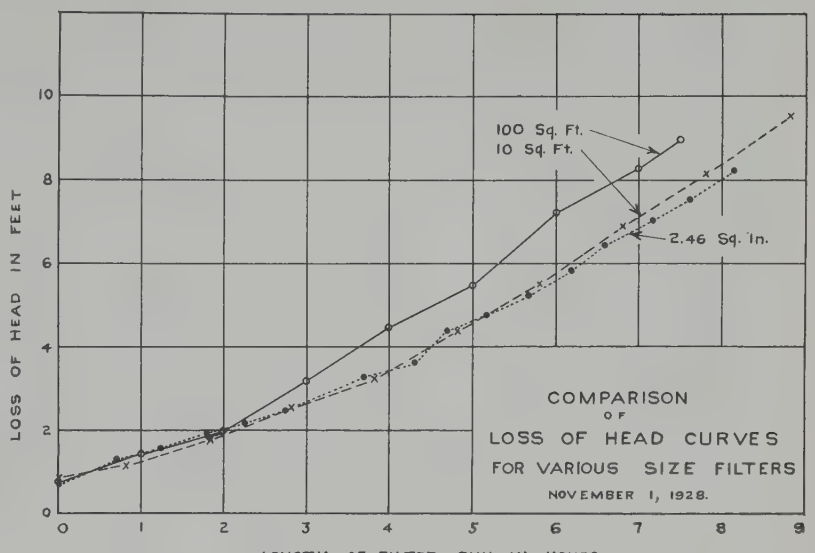

Fig. 9—Loss of Head Curves

The plant has a capacity of about 2 lb. of CO_2 per hour, which is sufficient for experiments using lime and iron. It is not enough, however, to recarbonate water to maintain a flow of 2 gal. per square foot per minute for one of the larger filters when the excess lime treatment is used. Having the smaller units the larger filters can be cut out and experiments using most any rate of filtration may be conducted with the present equipment. Should the work indicate that the excess lime treatment needs investigating more thoroughly the supply of CO_2 will be increased. It may be found cheaper to purchase the excess over the plant capacity in cylinders than to increase the capacity of the plant. It would be only a few experiments where it would be necessary to run the large filters.

The diffuser piping is a grid made of ¾-in. pipe, 6 ft. by 6.5 ft., with pipes spaced 2 ft. apart. The holes are 1/16 in. in diameter, point downward, and are spaced 6 in. apart along the pipes. This makes a total of 48 holes. The grid is connected by rubber hose to the supply line and may be suspended at any depth at any point in any of the settling basins. It is easily moved from one location to another without disconnecting the piping.

In giving this description of the plant no effort has been made to describe all of it in detail. It is only where the design is unusual or different from that of prevailing practice that detail descriptions are given. There are many things so near what may be found elsewhere that details should not be necessary. To illustrate: There are two chlorinating machines. They are Wallace and Tiernan machines just like those in many plants throughout the country. This applies to the chemical feeding equipment and to other parts of the plant.

Method of Conducting Experiments.—The method of conducting the experiments has been partially explained with the description, however, certain subjects will be discussed more fully. It is not intended to give the results of what is being found, for the paper is already too long for presentation in the time allotted. The work has been divided into 44 subjects, but the outline may be changed somewhat as the work progresses. Work is under way on the 23 subjects marked with an asterisk (*).

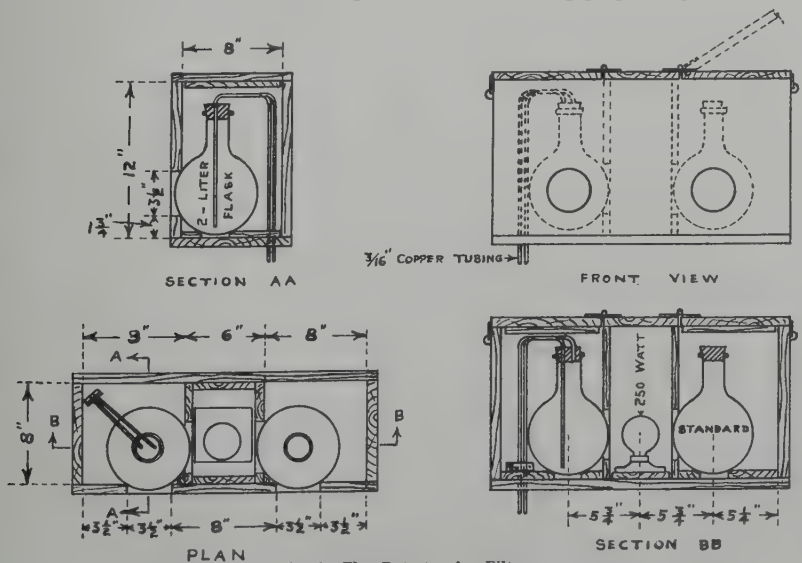

Fig. 8—Floc Detector for Filters

Outline of Experimental Work

1. Chemical Treatment.
   a. *Aluminum sulfate.
   b. *Ferrous sulfate and lime.
   c. Chlorinated iron.
   d. *Excess lime treatment.
   e. Lime and soda ash.
   f. Sodium aluminate.
   g. *Recarbonation.

2. Mixing Basins.
   a. Types of basins.
   b. *Time of mixing.
   c. *Violence of agitation.

3. Settling Basins.
   a. Size and type of basins.
   b. *Rate of settling produced by various treatments.
   c. Sludge removal.

4. Filters.
   a. *Rates of filtration.
   b. Size of sand.
   c. Kind of sand.
   d. Depth of sand.
   e. Gravel.
   f. Underdrains.
   g. Controlling apparatus.
   h. *Washing.
   i. *Surface wash.
   j. Air-binding of filter beds.
   k. Causes for clogging.
   l. Reverse flow agitation in lieu of washing during periods of short filter runs.

5. Chlorination.
   a. Prechlorination as an aid in chemical treatment.
   b. *Prechlorination as an aid in lengthening filter runs.
   c. Prechlorination as an aid in keeping the sand beds in good condition.
   d. Chlorine required to make the water safe bacterially.

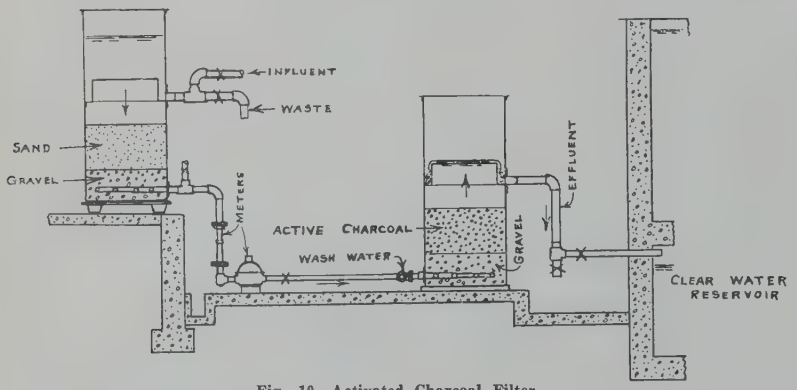

Fig. 10—Activated Charcoal Filter

6. Removal of Tastes and Odors.
   a. *Removal of phenol by excess chlorination.
   b. Removal of other tastes and odors by excess chlorination.
   c. *Activated carbon for the removal of phenols and other taste producing substances.
   d. *Activated carbon for dechlorinating water treated with an excess of chlorine.

7. Filtration Without Chemical Treatment.
   a. *Slow sand filtration.
   b. Rapid fine sand filtration.
   c. *Rapid coarse sand filtration.
   d. *Methods of filtration frequently used for industrial purposes.

8. Miscellaneous Items.
   a. *Duplication of plant results in the laboratory.
   b. *Measurement of the volume of coagulated matter.
   c. *Methods of testing for phenols.
   d. *Microscopical counts.
   e. *Effect of the size of unit on filtration results.
   f. *Special equipment and devices.
   g. Effect of certain trade wastes on filtration.

The Laboratory Part.—No description of the experiments being conducted would be complete without relating the part the laboratory plays in the work. Many of the problems are attacked first in the laboratory and then in the plant. It is possible to conduct experiments in the laboratory at a much less cost than they can be conducted in the plant. Not only this, but conditions can be varied greatly beyond the ranges of what may be accomplished in a plant, and this is frequently of great value in the interpretation of results or in obtaining specific proof of some point. The idea has prevailed heretofore that very little could be learned from laboratory as to the performance of a filtration plant. This has been due to the lack of the right kind of equipment and a knowledge of how to conduct the experiments. For our work, use is made of several pieces of equipment not found so extensively in water purification laboratories. The equipment consists of a stirring machine (Fig. 5), laboratory sand filter (Fig. 6) (centrifuge with 100-cc. tubes), turbidimeter (Fig. 7), and floc detector (Fig. 8).

With this equipment the water may be treated and filtered in such a way as to give very accurate duplication of plant results. To show that the laboratory filter will give duplication of larger filters, one of them has been set up in the plant and operated under the same conditions as the larger filters. Fig. 9 shows loss of head curves for filters having areas of 100 sq. ft., 10 sq. ft. and 2.46 sq. in., the smaller one being the laboratory filter. Every condition was the same, except the sand bed area, that is, the same water branched and went to the three units. The sand was the same depth and size, in fact it was all from the same pile of sand. The filters were operated under the same hydraulic conditions in that part of the head was positive and part negative, and the rates per square foot were the same.

It is not expected that two filters of the same area will give loss of head curves that coincide more closely. First one unit and then the other may show slightly longer or slightly shorter runs. The bacterial results average very closely for the three size units, just as closely as one would expect three filters of the same size to average. This also applied to the turbidity removal. In other words, the small laboratory filters and the small plant filters give the same results as the largest units. This fact greatly facilitates the work. Most of the time there are three to ten experiments under way in the plant and the laboratory.

Flexiblity of Plant.—To illustrate the importance of flexibility in the experimental plant, double filtration was not contemplated when the plant was constructed. There was no difficulty, however, in making the set-up as shown in Fig. 10 for testing activated carbons. In this case it is essential to have water going through the carbon bed.

The experimental work quickly demonstrated that handling the microorganisms so as to produce filter runs long enough for the practical operation of a large plant was going to be our major problem. For a period of six to eight months the lake water contains such an abundance of certain microorganisms that it would be difficult to operate when aluminum sulfate is used to coagulate the water. Ordinarily there is not enough turbidity in the water to materially aid in settling out the coagulated matter before it reaches the filters and a large percentage of the organisms go on to the beds. In some localities it is possible to kill the microorganisms and settle most of them out in large storage reservoirs, but it is evident that the microorganisms cannot be controlled in Lake Michigan. The water must be taken as it is and the trouble handled in some other manner.

It is not the purpose of this paper to give results of the experiments, but one or two things may be mentioned. The work to date indicates quite conclusively that some treatment other than aluminum sulfate will have to be used at least part of the time. This is a fact of major importance and it is doubtful if any designing engineer would provide for the use of a coagulant other than aluminum sulfate in the absence of the experimental work. This alone more than justifies the total expenditure for our work. The experiments also indicate quite conclusively that filtration rates greater than 125,000,000 gal. per acre per day may be used, another fact which, if confirmed by future experiments, will result in saving much more than the total cost of the experimental work.

There are many things relating to apparatus and to patented devices that need investigating. In the absence of definite figures a clever salesman may persuade the engineer to include something in the design not entirely suited for the work it has to do. The writer is aware of seven types of dry feed machines for feeding chemicals into the water, most of which are being actively promoted. The engineer has no information as to the relative merits of dry or solution feeds. There are five or six types of filter rate controllers, several of which are being actively promoted. A number of different kinds of filter bottoms and filter under drains have been used with not much information as to their relative merits. There are advocates of slow sand filtration and there are those who believe that this

kind or that kind of treatment should be used. It is admitted that a few of the experiments are being conducted primarily to keep the designers of the large plant from being annoyed unduely by the advocates of certain devices or equipment. Some promoters do not hesitate to take the fight over the engineer's head and it is well that he be fortified with facts.

It is hoped that these remarks will give a clearer insight as to the magnitude of the problem and to the importance of conducting experiments under conditions that give accurate and reliable information.

The writer wishes to express his appreciation of the courtesies being shown him in the work by Richard W. Wolfe, Commissioner of Public Works; Loran D. Gayton, City Engineer; and Henry A. Allen, Mechanical Engineer, in charge of the Operating Division of the Bureau of Engineering.

When the Experts Were Dismissed

An Inefficiently Operated Sewage Treatment Plant

By CHARLES CARROLL BROWN
Associate Editor Municipal News and Water Works

SOME years ago visits were made at intervals to sewage treatment plants in a city using Imhoff tanks which had the benefit of good engineering design, one at least of advice from Karl Imhoff. They also had the advantage of expert superintendents of operation and of the research conducted by them, so that the plants were pointed to by other cities as examples worth following. They had their troubles from time to time and some history was made and published, making known the methods used in overcoming these difficulties which were stepping stones in the advance of knowledge of a subject which is not yet too well known.

But changes in administration and increase in liberality of expenditures followed by drastic curtailing of appropriations, led to dismissal of experts and reduction of forces until a brief examination recently showed the results of neglect, lack of knowledge of proper methods of operation, inability to make the research necessary to keep up with the growth of the city and the constant tendency toward overloading the plant, and the lack of men enough to keep the plant in good clean operating condition.

When the plants were built, early in the history of the Imhoff tank in this country, they were located outside the city in the bottoms of the valleys of the creeks whose watersheds they serve, and the surrounding hills were forest or farm land, beautiful as scenery and highly eligible for first class city and suburban developments in estates and subdivisions.

Real Estate Development Around the Plant.—The good condition of the sewage treatment plants and consequent freedom from odors and other unpleasant features, evidently did not discourage the fine developments referred to, for now the hilltops are dotted with large estates, fine mansions and large institutions almost all round the horizon, and the better class of subdivisions, made beautiful by the best exercise of the city planners and landscape architects are crowding closer each year to the city property on which the plants are located, not only on the side next the city but around the area both ways.

Recently there have been complaints of odor nuisances and demands for their abatement, and some rather futile attempts at cleaning up are under way.

The city is far enough south to insure that the purification of the sewage on its way through the plant can continue throughout the year with little retardation from the action of cold weather, and it would seem to be easy to apply some of the modern methods of handling such treatment plants with a minimum of odors if not with practical freedom therefrom. Some of these methods were developed in these plants.

Present Condition of the Plant.—One of the plants was visited on a day so rainy in the morning that work on the plant was stopped before noon and only a negro watchman was on duty. The work on hand was a washing of all the stone in the filter beds and the effluent from the Imhoff tanks was discharging directly into an outlet ditch and thence into the creek. While there was a fair amount of dilution by the creek, enlarged by recent rains, the stream for the observed mile or so below the plant was of nearly the same color as the effluent from the plant, but under the drenching rain had no appreciable odor, although the influent of the plant had a noticeable odor of slightly stale sewage. Less favorable conditions of dilution of sewage and absorption of gases by the falling rain might well give rise to complaints from the neighbors of objectionable odors.

Checks on Operating Steps Lacking.—Observation of the tanks showed that, with the exception of one or two of them, the water surfaces of the flow-through chambers were kept clear, but nearly all the gas-chambers were foaming and overflowing into the flow-through chambers. Part of the gas chambers were provided with iron hoods to collect the gas, but the hoods and the connecting pipe were not maintained in good condition and much gas was leaking out of hoods and pipe as well as bubbling out of the water around the submerged edges of the hoods. This may have been due to the gas not being burned, at least when work is stopped on the plant. There were some indications that a considerable source of odors might be the sludge, drawn too frequently and so not completely decomposed and rendered practically odorless. The question then arises as to whether the plant is overloaded or is inefficiently operated. The inspection was brief and considerable time would be necessary to answer this question. Disuse of laboratory showed lack of checks on the steps in the operation of the plant, which might indicate the probable sources of the troubles.

This visit would not have been reported except for the facts stated as to its former good condition and its present poor condition and the rather evident inability of the present operators to determine the sources of the trouble and to apply tested methods of manipulation and treatment. It is the largest plant visited in the past two years which showed markedly poor results and suggests that there may be others of similar size which are in like condition. The weather conditions in the South are so much more favorable for efficient sewage treatment that there is much less excuse for an odorous plant than farther north, where artificial heat is sometimes used to supply the deficiencies of the winter climate and keep the processes of purification in efficient operation throughout the year.

The city referred to is nameless here, as some other city under like conditions of neglect of sanitary matters from political reasons or mistaken economy might well have happened to receive the visit during a like period of trouble from similar abandonment of the principles and necessities of efficient operation.

New York State Street and Road Contractors to Meet

The street and road construction industry of New York State will gather at the Hotel Syracuse, Syracuse, N. Y., March 13 and 14, in connection with the third annual convention of the New York State Highway Chapter of the Associated General Contractors of America. It is expected the state-wide gathering of this industry will attract hundreds of contractors from all sections of New York State. What is of interest to contractors is likewise of interest to material producers, equipment manufacturers, bonding interests, city and county officials, state and city engineers and all others allied with the industry.

The meetings will be held on the afternoon and evening of March 13, and on the morning and afternoon of the 14th. The banquet will be held in the Grand Ballroom of the Syracuse Hotel at 7 o'clock, Thursday evening, March 14. The banquet will be a friendly get-together with an elaborate entertainment furnished by the associate members of the organization and advertisers in its magazine.

Business Frontage and Its Relation to Population in Chicago Region

How much business property to plat in subdivisions and to zone for commercial use is the outstanding question always before the subdivider and the zoning authorities.

The Chicago Regional Planning Association believes that there is a definite relationship between population and the amount of business property actually in use. To find what that relationship is, measurements were made in 43 cities and villages in the Region of Chicago to determine the facts. Thirty-three of the communities measured were medium sized suburbs both residential and industrial, in varying directions and distances from Chicago. Ten larger cities were added, Evanston, a residential city directly adjoining Chicago, Kenosha, Chicago Heights, East Chicago, Aurora, Elgin, Joliet, Gary, Michigan City and Hammond, industrial communities from 29 to 57 miles away.

These measurements were made over a period of more than two years, 19 communities having been measured in the summer and fall of 1926, and the remainder in 1927 and 1928.

The 19 cities measured in 1926 were remeasured in 1928 and show substantially the same average.

At each place exact measurements were made of the ground floor store frontage actually in use and the number of stores was recorded in fifteen main classifications. Municipal and federal buildings were omitted. The population is an estimate from the most reliable sources.

Conclusions.—Approximately 50 ft. of business property are in use by every 100 people in the 43 cities and villages measured.

The character of the community (industrial or residential) has little effect on the amount of business frontage in use.

The size of the community makes little or no difference in the relation between population and business frontage.

Generally, the community which lies a greater distance from Chicago, in miles and minutes, has a larger amount of business frontage per 100 people. This is because the business frontage serves a population outside its corporate limits which is not represented in our population figures.

Recommendation. — The Chicago Regional Planning Association recommends that subdividers and zoning authorities adopt the figure 50 front feet of business for each 100 expected population as a basis on which to estimate the needed business property in subdivision plats and in zoning ordinances.

Convention of Illinois Water Well Drillers

The convention of the Illinois Water Well Drillers Association, held Feb. 12 and 13 at Urbana, Ill., was attended by practically 100 water well drillers and contractors located throughout the state. Some very interesting papers were read by contractors, engineers and members of the State Geological Survey and the United States Geological Survey. Practical talks were given on how to satisfactorily and economically perform practically all details of drilling and completing wells of all sizes, from small farm wells up to 200 ft. in depth to large municipal water works plants, where the wells would run in price from $15,000 to $30,000 each, and where the work would consist of constructing the entire plant such as well, pumping equipment of all sizes, pump house and reservoir and pipe lines.

The officers elected for the year 1929 are:

Chas. S. Cumming, President, Gardner, Ill.; B. L. Palmer, Vice-President, Aurora, Ill.; S. G. Geiger, Secretary, Chicago, Ill.; C. F. Steigman, Treasurer, Paxton, Ill.; Guy W. Peterson, Director for three years, Rockford, Ill.; Mike Ebert, Director for two years, Washington, Ill.; H. Meister, Director for one year, Tuscola, Ill.

The Convention for 1930 will be held in February of that year at Urbana, Ill.

Some Important Features of Sewage Disposal

A General Discussion of Matters Needing Consideration

By WYNKOOP KIERSTED
Consulting Engineer, 614 Interstate Bldg., Kansas City, Mo.

THE question arises whether we are progressing as well as we may and whether we are devoting our efforts along the right lines in the matter of sewage disposal. As our cities develop industrially, socially and intellectually we find new conditions arising which demand our best thought to meet them in the most satisfactory and economical way. The standards of living have been raised continually, and accordingly there is an increasing demand for more that contributes to social and intellecual welfare. Things that were once regarded as luxuries have become a necessary contribution to our daily wants and comforts. Among these changes there has been a great growth of civic pride and enterprise which exhibits itself in various ways as in the construction of beautiful buildings, the provision of parks, boulevards, recreational facilities of various kinds, assembly halls, and numerous other improvements which render a city beautiful, attractive and healthful. While there is much in geographical location to stimulate industrial development and urban growth still quite as much depends upon the enterprise and energy of the citizens. There is always a desire of every town to give prominence to some distinctive feature it possesses, either a natural resource, some special industrial development, unique public works, salubrious climate, but there is one thing that all aspire to, and that is clean and healthful surroundings.

Two Important Utilities.—Probably none of the other urban utilities contribute more to the comfort, economy and safety of civic life than a wholesome public water supply and water-carriage sewage. The two are linked together in too close relation to be successfully separated. The wholesome water entering the household or industrial works comes out grossly soiled and polluted, entirely unsuited to be retained upon the premises because of its putrescibility. It must be provided with facilities for a complete and steady outflow which can be utilized with a minimum of effort and a maximum of economy. This quick, effective and economical removal of putrescible household waste has engaged jointly the most intelligent effort of the ablest sanitarians and the best manufacturers of sanitary ware for many years and has culminated in the present-day water-carriage system of sewage and house drainage. Everything putrescrible and readily conveyed by water passes out of the household, out of the neighborhood and away from the community through well ventilated, securely jointed, impervious, closed conduits in the briefest possible period of time. The system is so simple of design, so provided with self-contained mechanical appliances of which no household tenant can mistake the proper manipulation and in its entirety so self-contained as to require the little operating attention needed in preventing obstructions by articles surreptitiously thrown into the street sewers. It is the common desire of the entire community that there shall be no interference with the service which the sewers afford and that such inspection be given the operation of the system as a whole, as to prevent any interruption of service. Any individual who deliberately attempts to interfere with the service is summarily halted. He is not allowed to jeopardize the safety or convenience of the community's interest in his own behalf. Moreover he is obliged to use the drainage system in accordance with prescribed regulations rather than to offend his neighbors by allowing putrescible and offensive waste to accumulate on his premises.

Even in the matters of detail, water-carriage sewage represents the combined effort of many intellects and it is regarded today as nearly ideal as humanly possible to make it, and until something better is evolved it has become a settled custom throughout the world upon which to base sanitary urban development.

Disposal by Dilution.—The question naturally arises what to do with the raw sewage after collection. The first thought is to discharge it into a water course or other body of water. This thought is purely subjective. The suggestion arises simply because of association with the water-carriage method of sewage. It is not the fruit of intelligent reflection. It is only an instinctive impulse which will not stand up under intelligent analysis.

The rights of a community are comparable with those of the individual. No community has the right to discharge raw sewage into a water course to the annoyance and injury of an individual or community located below it who have occasion to use the water of the stream or are annoyed by the odors of stranded putrefying matter. No city or industrial institution has the right to discharge raw sewage into a body of water agitated only by wind and tidal currents in a manner which will endanger the comfort or health or offend the aesthetic taste of those seeking recreational pursuits in or upon its waters. We know that such things are done, but we also know that an enlightened public opinion does not uphold the practice and will sustain any legislation honestly conceived and passed to protect the public safety and abate nuisances.

The argument is often made that every city obliged to obtain its water supply from a polluted source should protect itself against infection by purifying and sterilizing the water before use. The argument has weight when applying to pollution arising in Nature, but is made simply in defense of an evil when the pollution is man-made. Toleration of an offense of this kind is sometimes cheaper, and often politically safer than its abatement, at least for a time, or until an aroused public acts through its legal representative.

Objections to Dilution Method.—Outlets in deep water of raw sewage do not necessarily insure the requisite amount of dilution for natural purification, for the relatively warm sewage rises, seeking temperature equilibrium and at times floats on the surface to be widely dispersed by wind and wave. With similar outlets in the ocean the sewage invariably reaches the water surface by reason of its lower specific gravity. The lighter solids suspended in sewage and all the flotsam receive a wide distribution by wind and wave, and the life of pathogenic germs may be long enough, even in such an environment, to reach shoal water and infect sea food products, rendering sterilization compulsory. Without some such measure an infected locality of this kind may become a reservoir of infection for a large territory.

We can cast a hopeful look forward when we recall that our largest inland city, which for many years has attempted to dispose of raw sewage by dilution with water from Lake Michigan, is now engaged in constructing sewage disposal works of enormous proportions. New York is also planning purification works for a part of its sewage.

The organizations established for the purpose of arousing public interest favorable to legislation prohibiting the indiscriminate dumping of waste and filth into the water courses, for the preservation of a wholesome environment of the coast and lake beaches, for the restoration of conditions of lake and stream suitable for the higher order of fish life and for the preserva-

tion of wild life in general, are doing a good work. Health officials are also doing their part in educating the public and by rules and regulations, judiciously administered, are gradually getting effective action on the part of communities and are converting tourists through recreational districts like the forest preserves to a better regard for a higher standard of sanitation.

These organized efforts are sure to arouse the intelligent thought of the country to the realization that the disposal of raw sewage by the dilution method is not an ideal method of disposal and therefore should not and cannot prevail as a settled custom. It is the fruit of instinct and not of an enlightened intelligence.

Ordinary sewage contains scarcely more than one-tenth of one per cent of putrescible matter, of which about two-thirds is in solution and one-third is in suspension. That in solution is readily oxidized under favorable conditions, while that in suspension is difficult to oxidize, but can readily be reduced to an inoffensive condition by digestion. The existence of putrescible matter in these two states and the difference in the manner of reducing them to stable and inoffensive compounds is a fundamental consideration in the art of sewage purification. This distinction, although of utmost importance, is often ignored in the design of sewage purification works.

Sewage Farming.—For instance, where sewage farming is attempted without the separation of the putrescible matter in suspension from the dissolved portion, more or less objection has arisen because of offensive odors arising from the fermentation of stranded organic solids. This alone is sufficient to prejudice the majority of people against this method of sewage disposal and through prejudice to injure the marketability of the products of the farm. In fact the fertilizing value of the suspended matter in sewage is too small to offset the nuisance and injury arising from fermentation. Besides the insoluble matter is not in shape to be absorbed by plants. The situation is quite different with the putrescible matter in solution, for in this condition it is readily oxidized in percolation through the surface soil by bacterial activities into inorganic compounds in solution suitable for absorption by plant life—the water serving not only for transport but also as the agency through which the food supply can be assimilated. Therefore sewage irrigation is really restricted to dealing with the liquid portion of the sewage. In order to do this economically and inoffensively the separation of the matter in solution from that in suspension is highly desirable to say the least.

Condition of Sewage When Applied to Filters or Beds.—Another instance demanding consideration is the condition in which sewage is applied to the trickling filter or oxidizing bed. Here partially settled sewage, usually the effluent of Imhoff tanks, containing from 30 to 50 per cent of finely divided suspended matter, is sprinkled over a concrete lined bed of underdrained broken stone to facilitate the rapid oxidation by bacterial activity. No fermentation or putrefactive action is expected or provided for in these filter beds. Accordingly the large percentage of putrescible solids arrested in the filter must continue to accumulate, practically unaltered, until an overloaded filter is forced to disgorge or to clog. The disgorged solids, still putrescible, must be caught in a final settling basin and delivered into a digestion tank or dried on underdrained drying beds. The practice of putting into an oxidizing filter putrescible solids which cannot be materially changed in the process which oxidizes the putrescible matter in solution does not appear to be a logical proceeding. Why not prepare the sewage for the filter by first removing the solids and consigning them directly to the process suitable for their proper reduction? We know the trickling filter can remove putrescible matter in solution quickly and successfully and should do so with filters of less volume than is necessary when partially settled sewage is applied to them. Odors certainly will be reduced, there will be less damage of clogging and there is a strong probability that oxidation can be consummated without the aid of a final settling basin.

Advance Preparation of Sewage.—Is it not a fact that sewage purification has not advanced as rapidly as it should? It certainly looks so. It looks as though some fundamental considerations have been overlooked or neglected. There is much evidence to indicate that failure to do what is expected or desired is due, largely at least, to the neglect of properly preparing sewage for purification. This advance preparation should consist in a separation of the putrescible liquid from the putrescible solids with the following rule in mind, namely, that the putrescible matter in solution should go to the oxidizer and the solids to the digester.

The oxidizer may be a trickling filter, intermittent filtration bed, land in irrigation, aeration, dilution with large volume of water, or some other method. The digester may be a lagoon, an open tank or a closed tank with gas collector, whichever meets the local conditions most economically and successfully, but with the distinction that it be for "separate digestion."

Difficulty is conceded in the separation of putrescible matter in solution from that in suspension. Even so, if the rule as stated is fundamentally correct, a way should be found to overcome the difficulties at reasonable cost. It can be done within the practical limits of 90 per cent removal of suspended solids. And to achieve even better results economically is well worth the effort. As in the preparation of water for filters, so in the preparation of sewage for purification, the aid of a coagulant or of aeration or some other similar means to render the fine colloidal suspended matter settleable will undoubtedly be necessary. It follows then that there is need of a more extended use of well designed and well operated settling basins than has been customary heretofore. This additional cost will be offset, in a great measure at least, in a reduced size and cost of structures for purifying the liquid portion of sewage and possibly of the digesters which can then be operated more advantageously and scientifically under the "separate digestion" plan than is possible in the use of the two-stage tanks usually employed in the past.

Considerations of Fundamental Importance.—Even a cursory discussion of the question of sewage disposal cannot be attempted in this or any other brief paper. There are too many ramifications of the subject, each one of which constitutes a subject admitting of considerable elaboration. But every process or art, like the one discussed, possesses certain fundamental principles which must be thoroughly studied before they can be applied intelligently. And more than this it is essential to know the degree to which the application of fundamental principles can be modified to conform with the conditions and requirements in different localities. The author's attempt is to suggest a few considerations which he believes to be of fundamental importance which are now briefly recapitulated:

The disposal of raw sewage by dilution is a practice which appeals to instinct and not to an enlightened intelligence. It should be discouraged.

The purification of sewage in any manner demands advance preparation of the sewage, no matter what may be the process employed.

Since putrescible matter in solution can be most quickly reduced by oxidation and that in suspension by digestion the two should be separated as far as economically possible before attempting purification. In the settling basin 90 per cent or more of suspended matter can be removed. The effluent liquid of the settling basin should be purified by oxidation in a manner best suited to each locality. The settled solids when not dried and made into a fertilizer should go to a digester operated on the "separate digestion" plan with the by-products of digestion utilized wherever and whenever it is found feasible to do so. If oxidation by dilution is chosen the water should be of such volume as to insure sufficient residual oxygen for the support of the higher orders of aquatic life naturally peculiar to the locality.

Sterlization of the basin effluent is always in order where a special provision is needed to destroy infectious germs.

Causes of The Bruckner and The Fritz Weather Cycles

By HALBERT P. GILLETTE

EVERY treatise on meteorology mentions the Bruckner weather cycle, which is commonly assigned a period of 35 years.

Edward Bruckner published in 1891 (Klimataschwangkungen seit 1700) a remarkable monograph in which weather data for 120 years were given in great detail. In the Monthly Weather Review, October, 1928, many of Bruckner's data are given in a translation of an article written by Prof. H. Fritz in 1893. Prof. Fritz does not discuss weather, but he shows that it frequently is correlated with sunspots in a remarkable manner. When scientists express skepticism as to such correlations they should be referred to this article by Prof. Fritz as a starter.

The French meteorologist, Prof. E. B. Garriott, in a "Discussion of Long-Range Weather Forecasts" (Bulletin No. 35, U. S. Weather Bureau, 1904), said: "Bruckner's empirical cycle of 35 years, whatever its cause, undoubtedly exists in the Indian area. Under the title of the Grand Cycle it has long been known in Ceylon."

That the same weather cycle was known at least as far back as Shakespeare's time is evident from the following quotation from Sir Francis Bacon, given in "Climatic Changes" by Huntington and Visher: "There is a toy, which I have heard, and I would not have it given over, but waited upon a little. They say it is observed in the Low Countries (I know not in what part) that every five and thirty years the same kind and suit of years and weathers comes about again; as great frosts, great wet, great droughts, warm winters, summers with little heat, and the like, and they call it the prime. It is a thing I do the rather mention, because, computing backwards, I have found some concurrence."

There have been many attempts to find the cause of the Bruckner cycle, but hitherto without success. In "Engineering and Contracting," October, 1928, I outlined an electromagnetic theory of the cause of sunspots; and gave spot cycles caused by each of the eight known planets and several as yet unseen trans-Neptunian planets. Sunspots are, I believe, electromagnetic whirls caused by the magnetic fields of planets and certain comets. I believe that sunspots, in turn, cause the electromagnetic whirls in the earth's atmosphere that we call cyclonic storms.

It was shown in that article that Mars causes sunspots that reach a maximum every 19.5 months. To be more exact it is every 19.509 months. Mars revolves about the sun in 22.584 months.

$$19.509 \times 22 = 429.2 \text{ mo.}$$
$$22.584 \times 19 = 429.1 \text{ mo.}$$
$$\text{But } 429.1 \div 12 = 35.76 \text{ yr.}$$

This 35.76 yr. is the Bruckner cycle, I believe. At any rate it agrees closely with it, both as to length and as to time of occurrence.

I assume that the magnetic axis of Mars is not coincident with its axis of rotation, and rotates slowly backward, which accounts for the sunspot period being shorter than the orbital period. The axis of Mars is inclined nearly 24 deg. to the plane of its orbit, and when the magnetic axis is pointed most directly toward the sun the effect of its magnetic field upon the sun is greatest. This occurs every 429.1 months, as above indicated, or at the time when the axis of rotation is most inclined toward the sun and coincidentally the magnetic axis is pointing most nearly toward the sun. Since barometric gradients on the earth are greatest about when the sun's north pole is most inclined toward the earth, it may be assumed that it is the north pole of Mars that produces sunspot maxima at intervals of 19.51 months and of 429.1 months, the latter being the Bruckner cycle.

The Bruckner cycle is usually not a very pronounced weather cycle; and it requires a smoothed curve over a long period to make it clearly evident. From Bruckner's data the following peak years may be assigned to this cycle:

Bruckner Peaks		Mars Peaks
Cold	Wet	(35.76 yr.)
1738	1745	1738
1773	1775	1774
1813	1815	1809
1848	1848	1845
1878	1878	1881

The Bruckner peaks are in fairly close agreement with the peaks of the Mars cycle of 35.76 yr.; but it should be remembered that a much stronger weather cycle is the one caused by Jupiter, whose peaks are 11.2 yr. apart. A Jupiter peak was due in 1850, but for some reason it was modified by some other planetary body so that it came in 1848, which was one of the Bruckner peak years. And another Jupiter peak was in 1816.

According to C. F. Marvin (Monthly Weather Review, Feb., 1927) the rainfall at San Diego, Calif., showed a fairly well marked periodic curve with peaks in 1881 and 1917, the amplitude being about 15 per cent. This, it will be noted, agrees exactly with the long cycle of nearly 36 yr. that I have assigned to Mars, both as to peak dates and as to length of cycle.

Applying the same method of calculation used above in the case of Mars, I have deduced the following long sunspot cycles assignable to each of five planets:

	Yr.
Mercury	10.13
Venus	20.95
Earth	43.00
Mars	35.76
Jupiter	201.66

Four of these five cycles had been previously discovered, but their causes remained unknown. The 10-yr. and the 21-yr. spot cycles had been discovered by Sir Arthur Schuster. The 36-yr. cycle had been discovered by Bruckner. The 202-yr. cycle had been discovered by Fritz, who had regarded it as a spot and weather cycle of about 200 yr. It had been rediscovered by Clayton ("Earth and Sun," by Huntington, p. 231). Clayton used harmonic analysis of the sunspot numbers, and found a semicycle of about 100 yr., indicating a full cycle of about 200 yr.

There have been five outstanding errors made by most investigators of sunspots and weather cycles: First, they have often failed to distinguish the cycles due to one cause from those due to another cause. Second, they have thought cycles could vary greatly in length. Cycles can be easily confused with one another; and often a peak due to one planet is obscured or even obliterated by another planet; but the cycle assignable to each planet remains constant. Third, they have looked for similar weather conditions in nearby localities, not realizing that storm belts migrate in latitude. Fourth, they have by no means realized that there are a great many sunspot cycles. Fifth, most investigators have assumed that the cycles are multiples of one another in length; usually multiples of the great 11.2-yr. cycle. This springs from a false hypothesis, namely that there are internal forces in the sun that cause waves that are spaced at harmonic intervals.

Not only does each of the eight planets cause a spot cycle somewhat less than its orbital period, as I have shown in the article above cited; but there is clear evidence of many long cycles caused by unseen planets beyond Neptune. Moreover I have found so many short spot cycles that occur at or near the perihelion dates of comets, as to leave no doubt that some comets are sufficiently powerful to cause sunspots. This conclusion is startling only be-

cause astronomers have thought that if planetary bodies cause sunspots it must be through tidal effects produced by gravitation. They have ignored the evidence of powerful electromagnetic effects, as when the heads of certain comets contract enormously at perihelion.

The skepticism that still exists among many scientists as to definite relationships between sunspots and weather springs from the complexity of the forces involved, and from ignorance as to the nature of the forces. The skein is a tangled one, but it can surely be unraveled. For the purposes of the hydraulic engineer, as well as for many other practical applications, it is exceedingly desirable that this skein be unraveled as quickly as possible.

Third Annual Meeting Rocky Mountain Section American Water Works Association

The Rocky Mountain Section of the American Water Works Association held its third annual meeting in Denver, Feb. 14 and 15, 1929. A registration of 28 members and 55 guests, considerably more than that at any previous meeting, indicates the growth of interest in the section and its activities.

The address of welcome was delivered by C. C. Schrepferman, president of the Board of Water Commisioners of Denver. The technical papers presented were as follows:

"Distribution Systems and Service Pipes," by P. R. Revis, City Engineer, Cheyenne, Wyo.

"A Small Filtration Plant," by Chester Truman, Superintendent, Northfield Water Co., Colorado Springs, Col.

"La Junta's Sewage Pumping Plant," by Geo. E. Hine, City Engineer, La Junta, Col.

"Taking the Hardness Out of Water," by R. E. McDonnell, Consulting Engineer, Kansas City, Mo.

"Engineering Problems in Connection with Water Rights," by Geo. M. Bull, Consulting Engineer, Board of Water Commissioners, Denver, Col.

"Legal Problems in Connection with Water Rights," by Malcolm Lindsay, Attorney, Board of Water Commissioners, Denver, Col.

"Wells as a Source of Municipal Water Supply," by Wynkoop Kiersted, Jr., Consulting Engineer, Kansas City, Mo.

Round table discussions were held on mechanical vs. slow sand filters, prechlorination, and miscellaneous water works subjects.

Talks illustrated with lantern slides and motion pictures included:

"The St. Francis Dam Failure," by R. E. McDonnell.

"Water Purification and Sewage Treatment Equipment," by E. M. Kelly, representing The Dorr Co.

"Pipe Line Construction at Colorado Springs," by J. J. Wilson, representing the National Tube Co.

"Trenching Machines," by T. R. Elkins, representing the Wilson Machinery Co.

Demonstrations of coagulation, filtration and zeolite softening were given by E. W. Lasley, Vice-President, The Flox Co., and Dana E. Kepner, Colorado State Sanitary Engineer, both of Denver, Col.

Inspection trips included the shops and equipment yard of the Denver municipal water works, where demonstrations of tapping and other pipe work were given; and the plant of the Gardner-Denver Co., where the manufacture and operation of compressed air tools were shown.

Vaudeville entertainment, following the annual banquet, was made possible by a small registration fee paid by non-members.

The election of officers resulted as follows:

Chairman—P. R. Revis, Cheyenne, Wyo.

Vice-Chairman—D. D. Gross, Denver, Col.

Secretary-Treasurer—Dana E. Kepner, Denver, Col.

Directors (elected)—E. C. Gwillim, Sheridan, Wyo.; Wm. E. Neilson, Santa Fe, N. Mex.

Directors (held over)—D. V. Bell, Rock Springs, Wyo.; Paul S. Fox, Santa Fe, N. Mex.; E. A. Lawver, Ft. Collins, Col.; A. W. Stedman, Canon City, Col.

Exhibits of water works equipment were omitted, at the request of the Manufacturers' Association.

Relative Death Rates in Villages With and Without Public Water Supplies

There are ample data on the reduction in the general death rate, and especially in death rate due to water-borne disease in municipalities, which reductions are caused by the purification of a water supply of a municipality which previously had been supplied with water from a polluted source. Data regarding relative death rates in villages provided with public water supplies and those without public water supplies have been very meager. Some interesting information on this subject is given in Ohio Health News of Feb. 1, which contains the following tables for Ohio villages. The villages in each class are between 1,000 and 2,000 in population and the villages are located at widely separated parts of the state.

The 14 villages, without a public water supply during the period 1915 to 1927 inclusive, which were selected are as follows: Antwerp*, Cardington, Cedarville, Cleves, Doylestown, Georgetown*, Jamestown, Manchester*, Mechanicsburg, Richwood, St. Clairsville, Spencerville, Stryker and Yellow Springs*.

The 11 villages with a public water supply during this period, which were selected, are as follows: Addyston, Archbold, Baltic, Centerburg, Hubbard, Magnolia, Malvern, Mt. Blanchard, New Concord, Pleasant City and Shawnee. All these villages are provided with ground water supplies of satisfactory quality. The tables follow:

Death Rates in Villages Without Public Water Supply

Year	Total Population	Total Deaths All Causes	Total Deaths Typhoid	Average Population	Death Rate per 100,000 All Causes	Death Rate per 100,000 Typhoid
1915	18,473	288	6	1,320	1,557	32.5
1916	18,520	314	3	1,322	1.695	16.2
1917	18,594	298	3	1,327	1,602	16.1
1918	18,641	333	5	1,331	1,784	26.8
1919	18,688	308	2	1,334	1.650	10.7
1920	18,735	294	7	1,388	1,570	37.4
1921	18,783	270	6	1,342	1,438	31.9
1922	18,831	294	1	1,345	1.560	5.3
1923	18,879	345	1	1,349	1,825	5.3
1924	18,927	308	2	1,353	1,626	10.6
1925	18,975	302	2	1,356	1.590	10.5
1926	19,023	337	1	1,360	1,770	5.2
1927	19,071	293	1	1,364	1,535	5.2
Averages—13 years				1,342	1,620	16.4

Death Rates in Villages With Public Water Supply

Year	Total Population	Total Deaths All Causes	Total Deaths Typhoid	Average Population	Death Rate per 100,000 All Causes	Death Rate per 100,000 Typhoid
1915	11.640	134	1	1,058	1,152	8.6
1916	11,868	163	1	1,079	1,378	8.5
1917	12,098	154	2	1,100	1,273	16.5
1918	12,324	244	3	1,120	1,980	23.4
1919	12,652	141	0	1,141	1,113	0.0
1920	12,788	164	1	1,162	1,285	7.8
1921	13,016	136	2	1,183	1,044	15.4
1922	13,243	152	2	1,204	1,149	15.0

1927	14,384	146	0	1,308	1.016	0.0
Averages—13 years				1,183	1,189	9.5

It will be noted that the average population of the villages listed without a public water supply is more than those listed with a public water supply. It is to be expected that the typhoid death rate would be greater in the former than in the latter, 16.4 against 9.5 per 100,000, or 73 per cent greater, but the total death rate is also considerably greater, being 1,620 against 1,189 per 100,000, or 36 per cent greater.

While the conclusions to be reached from such a small number of municipalities are not necessarily final, they confirm the general conviction of public health authorities that a public water supply is a factor in improving the health of a community in other ways than merely reducing the death rate due to water-borne diseases.

*These villages have since 1927 either installed or have a public water supply under construction.

Zoning.—More than 640 cities, towns and villages in the United States now have zoning ordinances. These communities comprise close to 60 per cent of the urban population of the country.

Cost Accounting System Minneapolis Garbage Collection Department

Data on Garbage Collection Work in 1928

By GUSTAVE A. MOE
Cost Accountant, City Comptroller's Office, Minneapolis, Minn.

THE collection and incineration of garbage for the city of Minneapolis is done under supervision of the City Engineer. The house collection division consists of a fleet of 40 1½-ton trucks used as a single unit, each carrying one tank. A loading station is maintained to which these tanks are delivered. Unloaded from trucks these tanks are delivered by tractor truck and trailer in lots of six to the incinerator. The incinerator is located in the north end of the city. The loading station is in the south end of the city. Some garbage is hauled direct to the incinerator.

The area of the city is 58.7 square miles; average haul—8 miles; the maximum haul—14 miles; service rendered—weekly. The city requires all garbage to be wrapped and placed in cans at alley end of lot. Property owners furnish their own garbage cans. All collections are made between hours of 8 A. M. and 4 P. M. Drivers and collectors receive monthly salaries of $135 per month. They are allowed two weeks' vacation and two weeks' sick leave in each calendar year.

No ashes nor rubbish are collected by the city. No collection of garbage is made from downtown business places. This garbage is collected by hog feeders. They collect from hotels, cafes and large boarding houses, but are not allowed to collect from private homes.

Ledger Accounts.—The department prepares a budget for each year's operations. This budget estimate is prepared in October of each year for the next year's operation, and shows the amount of funds necessary under a code classification, which constitutes the general ledger accounts of the department.

A Cost Ledger is maintained which carries the cost control accounts of Office and Superintendence, Collectors' Salaries (helpers only), Truck and Trailer Operation and Maintenance, Garage Expense, Plant Expense, Vacations, Sick Leave and Compensation, Hauling, Loading Station to Crematory and Loading Station Expense. This Cost Ledger shows at all times the total costs of each account.

Subsidiary Ledger Accounts are maintained for each piece of equipment and each of the other accounts as shown on the cost ledger. Each account on the subsidiary ledger supports the detail information, control accounts then must reconcile to the accounts maintained on the General Ledger of the Accounting Division.

Salary Accounts.—Office and Superintendence Account is charged with the Salaries of the Superintendent, Route Foreman, Bookkeeper, Cost Accountant, Clerk and Claim Clerk, Auto Maintenance Allowance of Superintendent and Route Foreman, Office Supplies and Office Expense.

Collectors' Salaries Account is charged with the salaries of the helpers; there are two helpers with each collection truck.

Operation Account.—Truck and Trailer Operation and Maintenance Account controls subsidiary ledger accounts for each truck and trailer (trailers were used with a trail-a-Ford unit, but a new purchase of single unit trucks has now been made). Each truck is charged with operating expense, such as insurance, gasoline, oil, grease, alcohol, operator's salary; maintenance expense includes all repair labor, repair parts and proportion of repair shop expense. Depreciation is figured on a four year life after salvage value has been deducted. Storage and Equipment overhead is based on a per cent rate of tons collected. Tire Account is maintained for each tire, showing in detail miles of service, which is then charged to the truck as an operating expense. Trailer expense was kept in the same manner as trucks.

Miscellaneous Accounts.—Garage Expense Account is charged with all undistributed Garage Expense and is prorated to collection trucks as stated in previous account.

Plant Expense is charged with the

Summary of Truck and Collection Costs for 1928

	Collection Cost (45 Trucks)	Hauling, Station to Crematory (8 Trucks and Trailers)	Grand Total Cost of Collection
Operation	$ 52,928	$ 5,117	$58,045
Tires	1,440	----------	1,440
Trailer Cost	3,567	1,662	5,229
Insurance	298	53	351
Maintenance	8,269	2,303	10,572
Repair Shop Expense	4,779	332	5,111
Depreciation	11,174	2,132	13,306
Total Truck Cost	$ 82,456	$11,599	$94,055
Total Collection Mileage	268,514	26,593	295,107
Average Cost Per Mile	$0.307	$0.436	$0.319
Helpers' Time	$91,110	----------	$91,110
General Expense	$24,284	$1,689	$25,973
Total Cost	$197,850	$13,287	$211,138
Average Cost Per Mile	$0.737	$0.50	$0.715

Plant Expense, being Light, Heat, Repairs to Buildings and Watchman.

Vacations, Sick Leave and Compensation Account is charged with all vacation, sick leave and workmen's injury compensation and is shown as cost per ton of garbage collected.

Hauling from Loading Station Account is charged with expense of truck tractors from subsidiary ledgers, account of each kept in same manners as trucks.

Loading Station Account is charged with salaries of loading station men, supplies and insurance.

From the above accounts the reader will understand that a complete record of costs is being maintained. From these records reports for the executive, for the superintendent, the route foremen and the Council Committee are made, giving to them a measuring stick with which to measure the efficiency of this department. The worth of this system was recently demonstrated when bids for 25 new trunks were submitted; the new trucks were purchased upon the basis of facts brought out by the cost records of past performance of the trucks used by this department, which the engineer greatly appreciated when making his recommendations.

Cost Increases with Cold Weather.—The cost increases quite noticeable after September are due to several causes. The same route must be covered during entire year. In the cold months that follow September much garbage is burned at home, but not all, so collection must be made for partly filled cans. Tonnage drops, cost per ton goes up, also most difficult, icy conditions for collectors, while in warmer months more green vegetables, wet garbage—all have tendency to increase tonnage. Service is the same and the personnel is almost constant, although perhaps there is a small lay-off in the cold weather.

Cost Analysis for the Year of 1928

Office and Superintendence:		
Salaries	$	7,442.20
Auto Maintenance		540.00
Office Expense		1,275.99
Total Office Expense	$	9,258.19
Cost Per Ton (Office)		.31
Cost of Collection:		
Helpers' Time	$	91,110.23
Cost Per Ton (Helpers)		3.03
Truck Operation and Maintenance		65,010.09
Truck Depreciation and Insurance		11,472.05
Trailer Operation and Maintenance		1,367.98
Trailer Depreciation		2,049.72
Total Operation and Maintenance	$	79,899.84
Cost Per Ton (Operation and Maintenance)		2.66
Garage Expense:		
Labor	$	4,052.32
Supplies		881.04
Garage Equipment Depreciation		98.55
Total Garage Expense	$	5,031.91
Cost Per Ton (Garage)		.17
Plant Expense:		
Labor	$	2,280.48
Supplies		1,310.12
Insurance		131.00
Total Plant Expense	$	3,721.60
Cost Per Ton (Plant)		.12
Vacations, Sick Leave and Compensation		7,377.52
Cost Per Ton		.25
Total Cost of Collection	$	196,399.30
Total Tons Collected		30,042
Cost Per Ton (Collection)	$	6.54
Cost of Hauling—Stations to Crematory:		
Tractor Operation and Maintenance	$	7,452.24
Trailer Operation and Maintenance		436.75
Tractor Depreciation and Insurance		2,185.76
Trailer Depreciation		1,225.66
Total Tractor and Trailer Cost	$	11,300.41
Cost Per Ton (Hauling)		.89
Cost of Stations—Labor and Expense	$	3,438.32
Cost Per Ton (Stations)		.27
Total Cost—Stations and Hauling	$	14,738.73
Total Tons Hauled by Tractors		12,729
Cost Per Ton	$	1.16
Total Cost Delivered to Crematory	$	211,138.03
Total Cost Per Ton		7.03

Remembering also that 110,000 cans get service yearly at an approximate cost to the taxpayer of $2 per year or 4 ct. per collection per week.

Operating costs of trucks during winter months increase at least 25 per cent on account of increased consumption of gasoline and oil. Overhead expense also increases on account of fuel used to heat garage and buildings. Skid chains used in the winter months cost approximately $700, which also increases the cost.

Government Statistics of the Cement Industry for January

The ratio of the operations to the capacity of the American portland cement industry during the month of January was 46.5 per cent, according to figures released Feb. 15 by the Bureau of Mines of the U. S. Department of Commerce. During the month 9,781,000 bbl. were produced; 5,735,000 bbl. were shipped, and there were in stocks on hand at the end of the month 26,696,000 bbl. Production in January, 1929, was 0.1 per cent more, and shipments 12.3 per cent less than in January, 1928. Stocks at the mills were 6.3 per cent higher than a year ago.

Application of Highway Research Results to City Pavement Design and Construction

Effect of Character of Subgrade on Pavement Operations

By C. A. HOGENTOGLER
Senior Engineer, U. S. Bureau of Public Roads

The problems of both city and highway engineers differ in some respects, but on the other hand they are similar in many respects. The highway engineers' findings, therefore, may assist the city engineer in his work and the city engineers' experience may prove helpful in like manner to the highway engineer. We accordingly are printing herewith an abstract of a report presented Jan. 15 before the City Engineers' Division of the American Road Builders' Association at the annual convention of the association. The report was submitted by Mr. Hogentogler, Chairman of the Committee on Subgrades and Pavement Bases.

THE following definitions facilitate the discussion:

Breakage: Subdivision of concrete pavements or bases by cracks due to load. This includes transverse cracks spaced closely (3 to 5 ft. apart), longitudinal cracks in half-width (about 9 or 10 ft. wide) road slabs, corner and subsequent progressive cracking.

Cracking: Subdivision of concrete pavements or bases by cracks due to lack of uniform subgrade support, with or without load, to contraction caused by temperature or moisture change in the concrete or to shrinkage in the concrete. This includes transverse cracks spaced generally not closer than about 10 ft. apart and single longitudinal cracks in full width (about 16 to 20 ft. wide) road slabs, and also cracks which, during the setting of the concrete, may occur and subdivide pavements or bases into comparatively small fragments.

Dry Subgrades: Cohesionless sands or gravels resting above the ground water level. Any type of material resting very high about the ground water level (15 or 20 ft.) covered with a perfectly impervious pavement and being located where adjacent sidewalks and buildings prevent the possibility of surface water entering the subgrade soil.

Wet Subgrades: Until more is known about the efficiency of drainage for intercepting and removing water from the subgrade and for lowering the ground water level, it is a wise precaution to consider all graded materials, silts and clays which have access to water entering through cracks or joints in the pavement, grass plots or parks on the sides, and water bearing strata or capillarity from beneath as wet subgrades.

Influence of Subgrade Support.—The influence exerted by subgrade support upon pavement performance has long been recognized. Investigators of this problem until recently, however, have furnished only results limited in application to practical road construction. Realizing this situation the U. S. Bureau of Public Roads has attacked the problem and assisted by the U. S. Bureau of Soils and Chemistry, the Massachusetts Institute of Technology, the Ohio State University, the University of South Carolina, and the State Highway Departments of Maryland, Virginia, Ohio, New Hampshire, Missouri and Minnesota has made encouraging progress. A report now being prepared discloses this progress by

1. Pavement behavior as related to pavement design and construction, climate and subgrade support.
2. Subgrade support as related to both the raw constituents of soils and the attendant field conditions.
3. An arrangement of subgrade according to performance into a small number of practical groups.
4. The identification of the soils of each group by means of laboratory tests.
5. Theory which explains the stability of subgrades under service conditions.
6. The functions and practical application of drainage, subgrade treatments, porous subbases, compacted base courses, beam strength and thickness, crack control and steel reinforcement in rigid pavements as related to subgrade support.

Thus it suggests that preparation of the subgrade, selection of type of pavement and its design are not entirely arbitrary matters but depend instead upon the attendant subgrade soil conditions. And, consequently it explains how research findings can be utilized with profit in pavement practice.

Increased Subgrade Support Versus Stronger Pavements.—Stage construction employing admixtures of granular materials, bituminous materials, etc., furnishes the most promising possibility for increasing subgrade support. But the mere incorporation of granular material for instance is only one part of the stabilization process. Continuously vibrating and manipulating the soil when wet, dry, frozen and thawed, by traffic furnishes the other and the very necessary part of the operation. This requires time and consequently is generally impractical in city work.

The high stability of relatively thin old traffic bound roads or macadams therefore should not lead one to expect equal stability in newly constructed stone courses similar either in material or thickness, nor that the high support furnished by natural sand and gravel subgrades will be duplicated by moderately thick sand and gravel layers laid on clays. Thus when stage construction is not practical, designing the pavement to suit the subgrade support is more practical than attempting to improve the subgrade to suit a particular pavement design. This does not discredit, however, the use of precautionary measures for preventing loss of subgrade support.

Rolling the Subgrade.—The character and condition of the subgrade soil determines the extent of rolling required. A small amount of rolling to smooth off sands after they have been thoroughly sprinkled, seems to be sufficient. Compacting silts and fine grained clays with a very heavy roller breaks down their natural structure and thus, to the depth affected by rolling, increases their support.

Micaceous and distomaceous silts, coarse grained gumbo and fine grained clays containing organic matter, rebound upon removal of load. Consequently these subgrades are not permanently compacted by rolling. The micaceous friable soils may be compacted slightly when wet but are apt to expand upon drying. Due to their low density these subgrades furnish low support when either wet or dry. The adobes in contrast, are hard and compact when dry and may be temporarily compacted when damp. They expand very appreciably however when subjected to water, such as may be furnished for instance by capillarity or even that furnished by newly laid concrete.

Thus, in order to prevent detrimental volume change, an attempt should be made to obtain uniform density in elastic subgrades and to prevent their ab-

sorbing moisture during the setting of the concrete.

Porous Base Courses.—According to the Highway Research Board, base courses of cohesionless gravel, field stone, etc., laid on clays, not only fail to benefit rigid pavements in all cases but have been known to increase the extent of heave due to frost and the extent of breakage. This can easily be explained. Base courses containing large voids permit the evaporation and thus promote the flow of capillary moisture in the subgrade. Also they provide space in which free water entering from the road surface or from the subgrade and that furnished by the condensation of capillary moisture, may accumulate. Thus in the absence of drainage outlets, or when ice or lack of proper maintenance prevents drainage outlets from functioning, pourous base courses serve as reservoirs under the road surface. Under these conditions more water to produce frost heave is furnished by the presence than by the absence of porous base courses. Furthermore the large voids permit the penetration of the soft clay from beneath during thaws and may cause the base course to settle unequally, thus furnishing non-uniform support productive of pavement failure.

Substitution of cohesionless sand and gravel layers for high shrinkage adobe not subject to frost action, reduced the amount of cracking in a thin (4½ in. thick) concrete pavement in California. Also, according to Professor F. H. Roe, a sand base course reduced the length of longitudinal cracking in Ohio. Otherwise the presence of sand layers, according to available evidence, neither increases nor decreases the extent of cracking in superimposed concrete pavements of standard thickness.

To lead out water furnished by springs through separate drains, and to intercept that furnished by water bearing strata with trenches and tile drains placed under the edges of the pavement, seems preferable to using porous base courses promiscuously for drainage purposes. Except where rock subgrades furnish water through a number of crevices and where the thickness of base course can be made equally approximately to the depth of frost penetration, base courses containing large voids may not prove beneficial.

Compacted Base Courses.—Layers of well graded sand-clay, gravels with binder and compacted slag and crushed stone as under courses for rigid pavements may prove beneficial and as foundation for non-frigid pavements are of course a necessity.

Compacted slag bases, according to Professor Roe, were very much more efficient than porous base courses for reducing pavement cracking in Ohio. They also reduced cracking when used under concrete bases in Cleveland.

Tight compacted base courses, layers of sand-clay for instance, prevent the entrance of water into the subgrade from above and also the escape of capillary moisture by evaporation. They should therefore be more effective than porous base courses for preventing detrimental volume changes in subgrades having high shrinkage properties. Separating the sand-clay layer from the subgrade by a coating of light bituminous material will probably furnish additional protection against volume change in the subgrade.

When the subgrade support is low, but uniform, increasing the strength of concrete pavements or bases seems preferable to the use of subbases for obtaining insurance against load cracking.

Compacted base courses, however, in two way may serve to reduce the detrimental effects of concrete base cracking due to causes other than load. They eliminate to the depth of their thickness inequalities in subgrade support and therefore when properly drained may actually reduce in concrete bases the number of cracks. Or in contrast, by offering high frictional resistance to slab sliding, compacted bases may possibly increase the number but decrease the width of cracks in concrete bases and thus cause but little visible cracking to occur in the wearing course.

When contemplating the use of compacted base courses as foundations for non-rigid pavements two questions arise: First, can they be constructed properly, and second, is the thickness necessary to furnish adequate load distribution permitted economically?

Macadams for instance to be properly rolled and compacted require a firm subgrade reaction and this is not furnished by the elastic subgrades. The abrupt deflections with rebounds caused by traffic and possibly non-uniform volume change in these soils, are apt to seriously disturb subsequently such semblance of bond as might be obtained in these pavements initially.

Stage construction is apt to gradually work this elasticity out of the top layer of these subgrades and a very thick layer of well graded coarse materials with binder may facilitate the construction of macadams. Otherwise attempts to construct macadams on highly micaceous or coarse clay subgrades are apt to result in failure. The use of bituminous instead of mineral binders, in this case, furnishes a problem for future investigation.

Silts which are apt to become wet and fine grained clays which cannot be properly drained also are undesirable as subgrades for macadams. Initial compaction can be secured in the base course when these soils are fairly dry, but the thickness of base course required to furnish adequate load distribution on these very low supporting soils when wet is apt to be prohibitive. This is additive to the danger of ruptured bond due to excessive frost heave in the silts.

Newly constructed macadams may serve as satisfactory bases however on stiff clays and on silts when drainage lowers the ground water level in sufficient amount. Here precautions should be taken to eliminate the occurrence of soft spots in the subgrade and the penetration of the soft subgrade soil into the interstices of the macadam base course.

Three possibilities for guarding against this type of trouble are: Crowned subgrade with drains under the side edges of the pavement to intercept ground water and remove water which is apt to collect on the surface of the subgrade; separation of macadam from subgrade by means of a fine grained insulating layer to prevent soft soil from working upwards, and oiling of clay subgrades to prevent softening due to moisture absorption from above. The silts soften primarily due to capillarity from below and therefore may not be much benefited by the oil coat. Oiling and insulating layers may prevent also unequal settlement in porous base courses.

According to published report, fabric reinforcement has proven beneficial for preventing failure in compacted base courses laid on low supporting soils in England. The fabric reinforcement in this case is placed between the compacted slag base and the tar macadam top. The committee is attempting to secure additional information on the results furnished by this practice.

Quality of Concrete Bases.—Both the thicknesses of base and the quality of concrete required depend upon the subgrade conditions. Bases supported by soft wet subgrades must of necessity be thicker than those supported by firm, dry subgrades. Lean mix bases, however, on wet subgrades, even when made thicker than those on dry subgrades, may not prove serviceable because lean mix concrete is apt to disintegrate when subjected more or less continuously, especially in the presence of frost action, to excessive moisture.

The U. S. Bureau of Public Roads Impact Tests apply illustrate how subgrade condition influences the resistance of slabs, covered or not with bituminous tops to load breaking. This series of tests was performed on but one type of subgrade soil and under arbitrary conditions of load. Furthermore, the slab resistance was measured by impact instead of by static loads. Therefore the slabs thicknesses referred to below are illustrative, but unless substantiated by additional observations, they should not be applied to pavement design.

According to these tests a lean mix slab on a well drained subgrade requires a thickness of but 6½ in. to be equiresistant with a rich mix slab 6 in. thick. On the wet subgrade in contrast, a lean mix slab requires a thickness of 7½ in. to be equiresistant with a rich mix slab 6 in. thick. Furthermore, a rich mix slab on a wet subgrade requires a thickness of about 7½ in. to be equiresistant with a similar slab 6 in. thick laid on a dry subgrade and a lean

mix slab on a wet subgrade requires a thickness of about 8½ in. to be equiresistant with a similar slab 6 in. thick laid on a dry subgrade.

Also in the Bates Road Tests, the lean mix bases were less resistant than the rich mix bases to breakage. The subgrade in this case, it will be recalled, carries a high capillary moisture content (about 30 per cent by weight) which resists reduction by artificial drainage. Thus it conforms to the saturated subgrade in the Arlington tests.

According to Bulletins 1 to 7, inclusive, issued by the State of Illinois during the progress of the tests, the asphalt and brick pavement area requiring replacement was from 50 to 100 per cent greater in the lean mix than in the rich mix base sections.

The replacement area required, for instance, in the asphalt sections 14, 15, 17 and 20 (rich mix bases) was but two-thirds of that required in comparable sections 12-A, 13, 16 and 19 (lean mix sections). And the replacement area required in the brick top sections 27, 28 and 30 (rich mix bases) was but one-half of that required in the comparable sections 29-A, 29-B and 32-A (lean mix sections).

Disintegration of the concrete was observed in the lean mix bases laid on wet subgrades in Arlington, in the lean mix base laid on wet locations in the Chevy Chase Experimental Road and, according to A. P. Howell, Municipal Engineer, in old concrete bases generally in the Borough of Leyton, England.

Increasing the thickness of lean bases will not eliminate this objectionable feature. Therefore, the advisability of using them on wet subgrades is questionable. The rich mix bases to be equiresistant to breakage should be made thicker when laid on wet than on dry subgrades, or, as will be shown later, they should be reinforced with fabric when laid on the wet subgrades.

Steel Reinforcement.—This precautionary measure has been found effective for reducing the number of cracks in concrete pavements and the extent of breakage due to load. And when used in concrete bases, reinforcement has been found effective for preventing loss of sand cushion productive of failure in brick pavements, the occurrence of wide cracks in asphalt tops, and the faulting of base fragments which causes pavements laid on highly expensive soils to develop rough riding surfaces.

According to the Highway Research Board, "steel reinforcement reduces more economically than increased concrete thickness cracking in concrete pavements." Generally the Highway Research Board Report stated that mesh reinforcement 25 to 56 lb. per 100 sq. ft. and bar mat reinforcement 64 lb. per 100 sq. ft. reduced cracks more than one additional inch of concrete."

The average length of slab for instance in a large mileage of concrete roads, five years or more old, varied from 18 to 25 ft. In similar roads reinforced the average slab length was about 40 ft. According to P. M. Tebbs, the average length of comparable pavement slabs two years old in Pennsylvania were as follows: Plain concrete, 33 ft.; with 25-lb. mesh, 45 ft.; 65-lb. mesh, 67 ft. According to E. R. Hoffman, reinforced pavement slabs laid at bridge approaches, on new fills, on soft subgrades and on side hill fills in the State of Washington, suffered less cracking than similar slabs laid on more favorable subgrades but not reinforced.

In the DeKalb experimental road, 12 ft. wide and constructed by Dean A. N. Johnson in 1912, the average length of slab, after 13 years of service, were as follows: Plain concrete, 16 ft. long; 42-lb. mesh reinforced slabs, 50 ft. long.

These facts furnished by roads in service should not be discounted simply because they are not explained by available mathematical computations.

Also, according to the Highway Research Board, the initial load cracking, which is the beginning of breakage, is prevented more economically by thickness of concrete than by steel reinforcement. The extent of subsequent breakage, however, is very appreciably reduced by the incorporation of steel reinforcement. After test, the plain concrete Bates Road section (No. 54) 5 in. thick required replacement equaling 45 per cent of its original area. The comparable section (No. 55), of the same thickness but reinforced with steel fabric, in contrast required but 0.3 of 1 per cent of its original area to be replaced.

According to R. M. Morton, for instance (reporting on roads in Santa Barbara County, California), "Wire mesh and steel bar reinforcement did not always prevent cracks caused by subgrade settlement, but materially prevented the number of breaks and prevented cracks from opening and raveling.

When the subgrade settled from 1 to 4 in. under reinforced sections, cracks appeared around the edge of the depression. They did not ravel, however, nor cause unevenness of surface. When similar settlement occurred under plain concrete slabs, marked differences in surface elevation resulted with cracks open from ⅛ to ¾ in.

And, in addition to this, the mesh reinforced slabs laid on wet subgrades in the Arlington tests, resisted impacts very much larger (about 50 per cent) than similar slabs not reinforced.

Furthermore, according to information received by the committee, many British municipalities have found fabric reinforcement effective for preventing failure in concrete bases laid on low supporting soils.

Thus reinforcement may actually prevent cracks from forming, it may confine cracks to microscopic dimensions and within limits it prevents separation and faulting of pavement fragments, thus eliminating the excessive roughness which causes high impacts productive of further breakage.

Function of Wearing Courses.—Wearing courses do not necessarily increase the resistance of the bases to initial cracking caused by load. They protect, however, concrete bases against progressive breakage following initial load cracking and macadams against surface disintegration productive of total failure. Also, the good appearance of wearing courses is not appreciably changed by either frequent patching or replacement of small areas. Thus depending upon conditions, wearing courses may increase very appreciably the service value of pavements.

Data furnished by impact tests of the U. S. Bureau of Public Roads show that for slabs 4, 6 and 8 in. thick, consisting of either lean or rich mix or laid on drained or saturated subgrades, the addition of bituminous wearing courses failed to increase the resistance of concrete bases to load cracking. The Bates Road Tests substantiate this by disclosing generally that the presence of a wearing course exerted little or no influence on the resistance offered by concrete pavement slabs to corner cracking caused by wheel loads.

The Bates Road Bulletins referred to previously, however, disclose also the efficiency of wearing courses for reducing the extent of necessary pavement replacement. The replacement area required for instance in sections 14, 17 and 20 with bituminous tops is but one-eighth of that required in comparable sections 61-B, 54 and 52 without wearing courses. That required in sections 12-A, 14 and 17 with 3-in. thick bituminous tops is but one-fourth of that required in comparable sections 13, 15 and 18 with 2-in. thick bituminous tops.

The performance of city pavements generally bears witness to the protection afforded concrete bases by flexible wearing courses. Close observations clearly disclose that in many instances the bases are broken and furthermore that their fragments are displaced vertically. The roughness of the riding surface of such bases if not covered would probably be increased by attempts to maintain the many cracks, and by the further displacement and spalling of slab fragments due to contact with wheels of vehicles.

Impacts caused by this increased roughness combined with softening of the subgrade (depending on its character) due to entrance of water through the many cracks could be expected to rapidly increase the extent of breakage. A substantial wearing course prevents to some extent the individual movement of slabs, the entrance of water from above and thus very appreciably retards the progress of breakage in the base.

The protection afforded by brick wearing courses to concrete bases was

very clearly shown by the report on the Chevy Chase experimental road.

In the Bradley Lane experiments merely the addition of a wear and water resistant bituminous macadam wearing course changed a very unsatisfactory traffic bound road into a serviceable heavy duty highway.

The benefits furnished by wearing courses for preserving the integrity of bases are demonstrated more readily by reduced maintenance costs than by theories of mechanics. Nevertheless the protective action of wearing courses does not compensate for inadequate base strength. For also, according to the Bates Road Tests, one additional inch of concrete is more effective for reducing the extent of breakage due to load, than one additional inch of bituminous top.

Attempts to weaken the bars therefore when wearing courses are used may change into complete pavement failure the benefits which may be derived otherwise by covering adequate bases with substantial wearing courses.

Practical Application of Research Results.—Only experience can disclose the type and thickness of pavement required to give efficient service under the variety of conditions encountered in the various cities. The objectionable features developed by individual pavements subjected to particular service conditions, must be analyzed with respect to causative factors. Only then can the proper preventive measures be determined. Thus inspections of existing pavements to determine the current type of objectionable features and the application of research results to determine the proper preventive measures, furnishes the only rational basis for the design of pavements to be constructed in the future.

Conclusion.—Thus, according to research, every pavement operation from the rolling of the subgrade to the treating of the finished road surface depends upon the character of the subgrade. And furthermore the outstanding characteristics of subgrades can be identified in the laboratory. This does not, however, minimize neecssity for making examinations of subgrades in the field.

The corrective suggestions are of two kinds: Those which may be termed strong indications and those which may be regarded as established facts.

The strong indications require further substantiation before they can be accepted as recommendations for standard pavement practice.

The established facts, in contrast have been duly substantiated by the performance of roads in service and therefore should be applied in standard pavement practice.

Among the strong indications are:

1. Oiling clay and silt subgrades may greatly reduce the possibility of their working up into flexible base courses constructed subsequently. Meagreness of results furnished by this procedure prevents drawing conclusions. Practice deserves trial.

2. Insulating layers of fine grained granular materials prevents soft clays and silts from working up into interstices of overlying base courses. Substantiated more for materials with binder than for cohesionless materials.

3. Porous base courses serve to reduce extent of detrimental front heave under rigid pavement. Evidence contradictory. When used they should be both drained and separated from clays and silts by layers of fine granular materials.

4. Compacted base courses may reduce the amount of cracking in pavements due to non-uniform support and when offering high frictional resistance to slab sliding may reduce the width but increase the number of cracks due to construction and shrinkage in the concrete. Requires verification.

5. Drainage is effective for reducing the extent of cracking in rigid pavements and failure in flexible pavements. Evidence contradictory. True or not depending upon many conditions, only some of which are now known.

6. Light mesh reinforcement increases very appreciably the resistance of slabs laid on wet subgrades to initial load cracking. Evidence consistent but too meagre to furnish definite conclusions. This, if true, can be considered as an additional benefit furnished by reinforcement which should be used for other purposes in pavements laid on these subgrades.

Among the established facts are:

1. Increasing the thickness of concrete pavements increases their resistance against breaking into small pieces due to load.

2. Rich mix concrete furnishes more resistance to load breaking than less mixed bases.

3. The lean mix bases are apt to suffer appreciable disintegration when subjected to moisture and for this reason may not be suitable for wet subgrades.

4. Steel reinforcement is more economic than increased concrete thickness for reducing the number of length of cracks due to lack of uniformity in the subgrade or to shrinkage or contraction in the concrete.

5. Steel reinforcement tends to hold fragments of cracked slabs together and thus reduces the extent of spalling and faulting, in pavements. Also it serves to prevent progressive breaking down of pavements under load.

6. Wearing courses are essential to prevent disintegration beginning with surface abrasion in untreated traffic bound roads and macadams.

7. Wearing courses serve to protect cracked concrete bases against breakage due to traffic.

8. The full benefits to be furnished by the use of either steel reinforcement or substantial wearing courses can be obtained only when concrete pavements or bases have adequate resistance against initial load cracking.

Public Improvements Not Extravagance

The natural resources, creative ingenuity and productive energies which have made possible our tremendous city expenditures for streets, sewers, schools, bridges, water supply, civic centers, libraries, museums, parks, boulevards, transportation systems, elimination of grade crossings, street widenings, traffic control, slum clearance, harbor clearance, harbor developments and air ports, and the great pressure of the needs which have called forth these improvements have placed before our cities an unexampled temptation to extravagance. Nevertheless, the cities cannot be charged with lavish waste. With very few exceptions, the things built were needed long before they were completed. It is easy to make sweeping charges of extravagance; it is not so easy to name the street that should not have been paved, the bridge that should not have been erected, the school that is superfluous. If we are to judge by useless structures, city authorities have shown far more sagacity than have business men. For every folly of public construction I can show you a score of private follies. The true extravagance in public works has come not from engaging in unnecessary projects, but from unnecessarily high standards, from faulty planning, from relying upon inexperienced advice, from bad business methods, and from dealing with corrupt contractors and officials. For example, in Duluth, a few years ago, approximately $1,000,000 of unnecessary expenditure was eliminated from the plans of the new city hall as the result of a study of space requirements and the inauguration of an architectural competition, both of which were initiated by the local civic research organization and the Taxpayers' League of St. Louis County. Similarly in St. Paul, the Bureau of Municipal Research through better planning and design brought about an even larger reduction in the school building program. In both cases the improvements were needed. The danger of extravagance appeared not in the project itself, but in the unnecessary luxurious method of going about the work. This is an enhanced danger for cities as for individuals during a period of unexampled financial prosperity.—Extract from the annual report of Luther Gulick, Chairman Governmental Research Association, presented Oct. 15 at the 17th annual meeting of the association.

Five-Bladed Turbine Runner.—Adoption of a five-bladed hydraulic turbine runner, the first ever built, has made it possible to effect an estimated saving of 25 per cent in the total cost of the falls of the Ohio plant at Louisville, Ky.

How a Small Village Improved Its Water Supply

Spring Source Has Several Interesting Features

By FRANK C. ROE

Shields, Jordan & Roe, Hydraulic, Sanitary and Electrical Engineers, Chicago, Ill.

THE village of Niagara, Wis., was confronted in 1926 with the question of improving and increasing its water supply. A limited amount of money ($20,000) was available which created an interesting problem for the consulting engineers, who were called in late in the year to survey the situation and make a report.

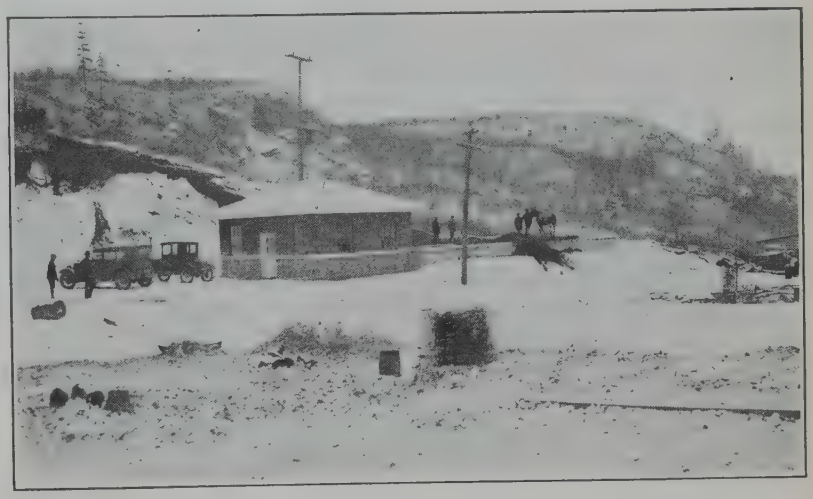
General Conditions.—Niagara is situated in Marinette County on the Menominee River. The terrain is unusually rocky and uneven except for some sandy bottom land, there being nearly 200 ft. difference in elevation between the high and low points within the village limits. The village is built adjacent to the large Kimberly Clark Co.'s paper mill, which is the only industry. The company owns a great majority of the property, pays most of the taxes, and hence was vitally interested in the problem. The mill of course is also the largest water consumer, even though the village water is not used for any part of the paper making process. The population was given as 1,943 in the year 1927.

The Former Water Supply.—The existing water supply in 1926 was from a shallow well drilled into the gravel and rock, within 50 ft. of the Menominee River and about 100 ft. from a similar well supplying water to the paper mill. The water became more unsatisfactory and unusable from year to year, presumably on account of fissures in the gravel and rock which permitted the river water to enter the wells. While there was no indication of B. coli present at any time, strong tastes of wastes from the paper mill were noticeable. The color corresponded closely to the river water which was yellow (40), had a turbidity of 30 P. P. M., total dissolved solids—87.1 P. P. M., and suspended matter—30 P. P. M. The hardness was 80 P. P. M. and the alkalinity 60 P. P. M.

Fissures also evidently opened between the two wells since the village supply became worse when the mill pump was shut down. In other words, the pasage from the village well through the mill well and to the river was more free than the passage directly between the river and the village well. It became necessary to pump continually for 24 hr. to maintain the supply, although this was found to be due to leaks which were located after the construction of the new works, and which will be discussed later. However, the apparent lack of quantity added to local dissatisfaction with the existing supply. The pump in use was barely able to lift water to the bottom of the equalizing reservoir, and then only during the night; so the average pressure was lower than desirable.

New Supplies Considered.—Four separate sources and schemes for a new supply were considered, namely: filtered Menominee River water, impounded and filtered surface water, deeper wells located at an appreciable distance from the river, and infiltration galleries in spring areas. The costs of the first three mentioned were prohibitive and the quality questionable in the first scheme. The practicability of utilizing the spring water source hinged only on quantity since the cost would be very low in comparison with the cost of utilizing other sources, and the quality was excellent. Accordingly weirs were installed to measure the quantity from two separate spring areas, namely: the Burden Springs and the Harding Springs. The flow out of the Burden Springs varied between 60,000 and 130,000 gal. per day. The Harding Spring was more variable since it was located on higher ground. Two other springs were considered and rejected, one because of inaccessibility and the other because of insufficient supply.

Since the village consumption of water as shown by the service meters (excluding that used by the paper mill) was only 21,000 gal. per day, the plan of building infiltration galleries was adopted and the Burden Spring selected for the supply. The other springs of course are still available in case the demand increases beyond the present supply, which condition is unlikely. Other reasons for selecting the Burden Spring were, that it was closer to a pump house and reservoir site, closer to the existing distribution system, and actually had the best quality of water. The iron content was 0.1 P. P. M. magganese 0.0 and the bacterial count was 40 per c.c. at 37° C. with no trace of B. coli.



Pump House and Reservoir

Plans were prepared in the spring of 1927 and construction completed in October, 1927. The essential parts of the project are the infiltration gallery, receiving chamber, 160,000-gal. storage reservoir, pump house, pumping equipment, and connecting pipe lines.

The Infiltration Gallery.—The infiltration gallery consists of a main 572 ft. in length of 12, 10 and 8-in. diameter pipe, laid through the center of the spring area, with seven 8-in. diameter branches, to particularly good springs, which bring the total length to 804 ft. The pipe is standard vitrified bell and spigot tile pipe laid with open joints. The ditch was hand dredged from 3 to 6 ft. deep and each length of pipe laid with the aid of an improvised wooden box, or the flowing sand (the gallery being below the water table) would have inundated the

pipe before it could be set correctly and the gravel placed. Immediately after setting a length of pipe, coarse gravel (¾ to 1½ in.) was placed all around it at least 6 in. in thickness followed by a course of clean sand or very fine gravel of the same or greater thickness, before the box was removed and the sand from the sides allowed to flow.

The lower end of the main collecting tile enters the receiving chamber where the velocity of the water is retarded sufficiently to enable any sand to be retained; the clear water continues through by gravity to the storage reservoir. A drain line is also connected to the receiving chamber which permits the total flow to by-pass the reservoir thus facilitating cleaning. The chief reason however for this separate receiving chamber was that the topography made a pressure pipe or "inverted siphon" of some 200 ft. length necessary between the lower end of the gallery or collecting pipe and the storage reservoir. Since the pressure pipe rises into a weir box in the pump house adjacent to the reservoir, it was essential that no sand suspended in the water enter it at the higher end thereby promoting a possibility of clogging at its lower elevation.

Interior of Pump House

The Reservoir and Pump House.—The weir box in the pump house is constructed of concrete and covered with glass. Flow is thence by gravity to the adjacent reservoir. The flow line over the 16-in rectangular brass measuring weir is approximately the same elevation as the high water line in the reservoir so an overflow weir was located opposite the measuring weir, the crest of which is 3 in. higher than the measuring weir. Thus when the reservoir is filled the flow automatically enters the overflow which is connected to the aforementioned drain. The reservoir is of reinforced concrete 34 ft. wide, 56 ft. long and 14 ft. deep.

The pump house is constructed of reinforced concrete, stone and pressed brick. It contains in addition to the weir box: a vacuum pump, two 4-in. by 3-in. Allis-Chalmers horizontal centrifugal pumps directly connected to 25-H. P., 3,500-R. P.M. motors, pressure control equipment, pipe gallery (below), and a Brown electric flow meter (indicating, integrating, and recording) of the orifice plate type.

The pump suction is connected to the reservoir and the discharge is directly into the distribution system, the connection being only 200 ft. distant. The former equalizing reservoir of 50,000-gal. capacity continues to serve as such. It is located some 145 ft. above the pumps. The level is maintained in the equalizing reservoir with a differential of 4 ft., by means of a Golden-Anderson altitude valve. When both pumps are placed in series for fire pressure the altitude valves serve another purpose by automatically closing before the reservoir reaches the high water level.

When operation started in October, 1927, the demand for water appeared to be almost as great as the supply and was over 100,000 gal. per day, or nearly 80,000 gal. more than the service meters indicated. A survey showed a leak of about 60,000 gal. per day in a 3-in. service line to the paper mill and the remainder was accounted for by wide open inlets to sewer flush tanks. The recorded flow at the pump house now checks closely with the meter readings, although the domestic consumption has increased considerably beyond the previous 21,000 gal. per day average, due to the great difference in quality of water.

The flow of water from the springs appears to have increased during the past year, although this fact may result because there has been no protracted dry weather period. At no time were readings lower than 100,000 gal. per day recorded, while the maximum rate was approximately 140,000 gal. per day. There has been no change in quality.

Although definite data are not available, the cost of operation, including the services of an operator, is lower than that of the former supply, being about $1,500 per year. The total average cost of pumping per million gallons 1 ft. high is estimated at $0.95, including the operator's salary.

All of the pipe work, including the infiltration gallery, was installed by a village crew under the direction of the superintendent of streets.

The reservoir, pump house and receiving chamber were constructed by the C. R. Meyer & Sons Co., General Contractors, Oshkosh, Wis. The works were designed and the construction supervised by Shields, Jordan & Roe, Hydraulic, Sanitary and Electrical Engineers, of Chicago, Ill.

27,000 Fatalities Auto Toll for 1928

Twenty-seven thousand people were killed in automotive accidents during the year 1928. A daily average of 87 fatalities during the month of December brought the year's total up 5 per cent higher than the record for 1927. The jump during December is the highest of any month during the year just closed. Twenty-seven hundred fatalities represents the month's toll.

There may be a grain of consolation in the fact that the 5 per cent increase between 1927 and 1928 is just half the percentage increase between 1927 and the preceding year, and the lowest increase in any year since 1920.

Washington, D. C., stands out in bold relief among the larger cities with no fatalities for December.

Half of the pedestrians killed during December were 55 years of age or over.

Ninety-two cities and eight states, representing a population of 46,000,000, reported to the National Safety Council which compiled the statistics.

The death rate in the cities over 500,000 population is shown below. The figures in the fifth column, headed "Death Rate," are annual rates per 100,000 population. The populations used in computing these rates are furnished by the U. S. Census Bureau.

(Over 500,000 population)

City	December 1928	December 1927	12 Months 1928	12 Months 1927	Death Rate
Baltimore, Md.	17	9	136	139	16.4
Boston, Mass.	11	11	118	115	14.8
Buffalo, N. Y.	19	9	123	122	22.1
Chicago, Ill.	108	78	909	824	28.8
Cleveland, Ohio	26	24	232	218	23.0
Detroit, Mich.	40	38	330	397	23.9

Municipal Tax Rate in Massachusetts.—The average tax rate of all municipalities in Massachusetts is $28.42 per $1,000 of assessed valuation.

Size and Behavior of Sand in Rapid Sand Filter Plants

Methods of Examining and Comparing Sands

By PAUL HANSEN
Of Pearse, Greeley & Hansen, Consulting Engineers, Chicago, Ill.

THE bed of filtering sand has received less study and has undergone less change than any other element in rapid sand filter plants since this type of filtration received general recognition in the late nineties as an effective means for the purification of public water supplies.

The Fuller Experiments.—The report of George W. Fuller on his classic experiments at Louisville, Ky., in 1897, makes but brief mention of factors controlling the design of the sand bed. He commented on the difficulty of determining the most favorable thickness of sand bed and size of sand grains because of the obscuring effect of various other items, more particularly coagulation and sedimentation. He thought the 24 in. of crushed quartz in the Warren filters too thin and concluded that less expensive clean natural sands were equally effective. He also considered the 4 or 5 ft. of sand in the Western filters too thick. The 30 in. of sand in the Jewel filters seemed to be reasonably satisfactory. Little was adduced with reference to size of sand grain. The crushed quartz in the Warren filters had an effective size of about 0.51 mm. and the natural sand in the other filters had an effective size of about 0.43 mm.

Without further inquiry of importance a thickness of sand of 30 in. has been generally accepted as about right from the time of the Louisville experiments to the present day. The size of sand grain has likewise remained essentially the same. As a result of observation at the operation of the Little Falls, N. Y., filter plant, built in 1902 for the East Jersey Water Co., there was a tendency to reduce the effective size of the sand grain to 0.35 mm. and this remained the standard size until recently, and is even now often specified.

Ohio Studies of Purification Plants.—Observations of the Ohio State Department of Health beginning with the special study of water purification plants in 1908 indicated that with sand grains having an effective size of more than 0.35 mm. the purification was not always satisfactory. However, the conclusiveness of these observations has been disputed. With the acceptance of sterilization with bleach or chlorine there has been a tendency toward larger sand grains up to about 0.50 mm. This functions better with the high rate of wash water first adopted at Cincinnati in 1907, gives longer filter runs and is less troublesome when microscopic organisms are numerous.

Changes in Filter Design.—Every other feature of rapid sand filter installations has changed so greatly that a filter plant of the early type common in the 1890's would hardly be recognizable as embodying the same general processes as a plant built in the last decade. Concrete has replaced wood, rectangular instead of circular filter units are nearly universal, compact and convenient arrangements have been worked out, much larger filter units are in common use, filter valves are hydraulically or electrically controlled, mixing chambers have become an important feature, elaborate and improved methods of chemical feed have been developed and better housing has been provided. Many of the latest and largest plants are embellished with architectural effects of a high order, whereas in the olden days a plain brick building or a galvanized iron shed was regarded as good enough.

Method of Specifying Sand.—The first pronounced movement for a closer examination of filter sand began in about 1916 and took the form of a rebellion against prevailing methods of examining filter sand. Up to that time, the method devised by Allen Hazen in 1892 for sand examination and recording had been accepted without much question and engineers were in the habit of specifying sand by designating a certain "effective size" and "uniformity coefficient," terms devised by Hazen as a measure of the filtering characteristics of sand. Effective size is that size of sand grain of which 10 per cent by weight is finer than; uniformity coefficient is the ratio of that size of sand grain of which 60 per cent by weight is finer than to that size of grain of which 10 per cent is finer than.

Objectors to this description of sand were opposed to it on two counts, namely, (1) that the stratification that takes place in a rapid sand filter as the result of washing with a rising current of water renders the terms effective size and uniformity coefficient no longer applicable as terms descriptive of filtering characteristics, and (2) that the use of millimeters and the terms effective size and uniformity coefficients were mystifying to the average contractor or dealer in sand and, also, to many engineers.

The Hazen Method.—To do Hazen credit, it should be pointed out that he never recommended specifying sand by naming the desired effective size and uniformity coefficient and it has always been his practice to specify the percentages by weight lying between specified mean diameters as determined by shaking a sample through a set of carefully calibrated sieves. In other words, he placed more importance on the entire plotted curve of sand grain sizes than he did on the two points which determine effective size and uniformity coefficient. But these terms seem to have caught the popular fancy among engineers and as they could be written into specifications with less thought and effort than was required to describe the full analysis, the temptation to use them has been strong.

Standard Sieves.—As an alternative to the Hazen method (as generally used), objectors proposed a specification based on separations by standard sieves but it soon developed that standard sieve cloth was not being made with sufficient uniformity of weave nor did different manufacturers conform to a common diameter of wire. If sufficiently accurate and uniform sieve cloth could be obtained it would unquestionably simplify sand analysis because calibration of sieves, according to the Hazen procedure, is a rather difficult and tedious process and, in fact, was often neglected.

As a demand had developed in a number of industries for standard sieves, the United States Bureau of Standards undertook to establish a standard set of sieves. The openings in the complete set varied in the ratio of the fourth root of two. By omitting every other sieve the openings would vary in the ratio of the square root of two. This latter series is most suitable for sand analysis. This ratio of variation is a convenient one and lends itself readily to plotting. It was also proposed to designate the diameter of sieve openings in microns so that whole numbers could always be used. If millimeters are disturbing to the intellect of contractors and sand dealers, the use of microns might prove disastrous.

To meet the limitations in methods of manufacture, and, also, variations in the products of different manufacturers, certain tolerances in both openings and wire diameters were permitted. In 1926, a committee of the American Society for Testing Materials, in co-opera-

tion with manufacturers, adopted the standards of the Bureau of Standards tentatively.

Care Needed in Use of Sieves.—These standard sieves are fairly satisfactory for the examination of filter sand, but care should be exercised to use sieves that have been examined and checked by the Bureau of Standards, a service which the bureau renders for a very moderate fee. The sieve separations may be approximately converted to mean diameters, as defined by Hazen, by multiplying the sieve opening by the factor.

Results obtained by the use of standard sieves may vary from results obtained by calibrated sieves, according to the Hazen method, by as much as 5 per cent. In view of the greater accuracy of the Hazen method, and the large amount of data that have been and are being obtained by his method, the committee on Sand Testing and Recording of the American Water Works Association has not as yet deemed abandonment of the Hazen method advisable.

Behavior of Sand Beds.—While methods of examining and comparing sands are necessary there are many behaviors of sand beds in connection with which little has been done and little is known. The greatest advance in the study of these behaviors was made by Baylis at Baltimore in studying cracking and mud ball phenomena. He was able to relate these to the accumulation of organic matter and organisms about the sand grains and he elaborated microscopic methods of examining these accumulations, which have given us a much better understanding of their functioning, for both good and evil. Microscopic examination of sand grains has now become a routine practice in a number of large filter plants.

The Am. Soc. C. E. Studies.—In 1928, James W. Armstrong, acting in behalf of a committee of the American Society of Civil Engineers on filter materials for sewage and water works, of which William E. Stanley is chairman, enlisted the co-operation of some fourteen filter plant operators, including Mr. Baylis at the Chicago Filter Testing Station, in carrying on experiments on the behavior of filter sands under a variety of conditions and with different waters. The general object of these experiments is to determine the optimum size of sand grains and the best depth and grading of sand beds to meet the requirements of waters of different types. The experiments are being made in batteries of seven glass tube filters attached to and operating in parallel with a full size filter. One of the seven glass tube filters is provided with the same sand as is contained in the large filter and is maintained as a control. The others are provided with sand beds of different sizes and depths, the sand being prepared uniformly by Mr. Armstrong in Baltimore and shipped to the various experimenters. Certain uniform procedures and observations have been adopted, but they are subject to variations and elaboration as the experiments progress.

After many years it now appears that we are on the way to a careful study of behavior of the sand bed in rapid sand filters. Whether these studies will result in changes in the design of the sand bed, remains to be seen. Whether they do or do not result in changes in design, they have already and will continue to add to our knowledge of behavior and, hence, add to our ability to control the performance of filter plants.

Acknowledgment.—The foregoing paper was presented at the 1929 Convention of the Illinois Society of Engineers.

Research Graduate Assistantships at University of Illinois

To assist the conduct of engineering research and to extend and strengthen the field of its graduate work in engineering, the University of Illinois maintains fourteen Research Assistantships in the Engineering Experiment Station. Two other such assistantships have been established under the patronage of the Illinois Gas Association. These assistantships, for each of which there is an annual stipend of $600 and freedom from all fees except the matriculation and diploma fees, are open to graduates of approved American and foreign universities and technical schools who are prepared to undertake graduate study in engineering, physics, or applied chemistry.

An appointment to the position of Research Graduate Assistant is made and must be accepted for two consecutive collegiate years of ten months each, at the expiration of which period, if all requirements have been met, the degree of Master of Science will be conferred. Half of the time of a Research Graduate Assistant (approximately 900 clock hours for each ten-month period) is required in connection with the work of the department to which he is assigned, the remainder being available for graduate study.

Nominations to these positions, accompanied by assignments to special departments of the Engineering Experiment Station, are made from applications received by the Director of the Station each year not later than the first day of April. The nominations are made by the Executive Staff of the Station, subject to the approval of the President of the University. Nominations are based upon the character, scholastic attainment, and promise of success in the principal line of study or research to which the candidate proposes to devote himself. Preference is given those applicants who have had some practical engineering experience following the completion of the undergraduate work. Appointments are made in the spring, and they become effective the first day of the following September. Vacancies may be filled by similar nominations and appointments at other times.

The Engineering Experiment Station, an organization within the College of Engineering, was established in 1903 for the purpose of conducting investigations in the various branches of engineering, and for the study of problems of importance to engineers and to the manufacturing and industrial interests of the State of Illinois. Research work and graduate study may be undertaken in architecture, architectural engineering, ceramic engineering, chemistry, civil engineering, electrical engineering, mechanical engineering, mining engineering, municipal and sanitary engineering, physics, railway engineering, and theoretical and applied mechanics.

Additional information may be obtained by addressing M. S. Ketchum, Director, Engineering Experiment Station, University of Illinois, Urbana, Ill.

Course in Traffic Engineering

The School of Engineering of the University of Pittsburgh is conducting a course in traffic control engineering. The course began Feb. 15 and will continue for 15 weeks, meeting each Friday evening from 7:50 to 9:30. Enrollment was opened to anyone who is interested in the traffic problem. The fee for the course was $15.

The course covers the following subjects:

Traffic surveys and statistics; city and regional planning and street design; traffic delays; traffic signs, signals and other guides; electric traffic control systems and their design; organization of traffic educational campaigns; planning to prevent traffic accidents; organization and functioning of traffic bureaus; study of enforcement procedure; typical traffic laws and ordinances; terminal facilities; work of police departments; the parking problem, including a study of its economic aspects; segregated and through traffic streets; elevated and express roadways; pedestrian control; mass transportation and its relation to traffic congestion; zoning and decentralization; the taxicab problem; methods of increasing street capacity; regulation of traffic moving on conflicting routes.

Professor Lewis W. McIntyre, who is conducting the course personally, is in charge of the highway and highway transportation work at the university, and is vice-president of the National Highway Traffic Association and consulting engineer to the city of Pittsburgh on the downtown electric traffic control system.

The course is designed especially to interest and instruct those engaged in design, construction and operation of highways, the regulation of traffic and reduction in traffic accidents.

A New Method of Spreading Rock Asphalt

How a Concrete Finishing Machine Was Used

By JOHN L. HUMBARD
President John L. Humbard Construction Co., Knoxville, Tenn.

A STANDARD concrete-finishing machine, with an added raking device, is being used in constructing a 9-mile pavement of Kyrock on a concrete base, in Cheatham County, Tennessee. Similar machines have been used to spread natural rock asphalt laid cold. The rock asphalt is being laid on a 7-5-7 in. (parabolic curve) concrete base, with a 1¼x6-in. curb on each edge. The base, too, is finished smooth and a paint coat is applied ahead of the asphalt.

The rock asphalt is dumped in piles on the base ahead of the finishing machine, as shown in Fig. 1. Men with shovels then roughly spread the piles, throwing the material back in front of the rake, as shown by Fig. 2. It then contains many lumps, and the purpose of the rake is to break these down, even up the asphalt layer and provide a fine, homogeneous material ahead of the finishing machine screed. Except for the added raking device, the machine is of standard construction in every respect.

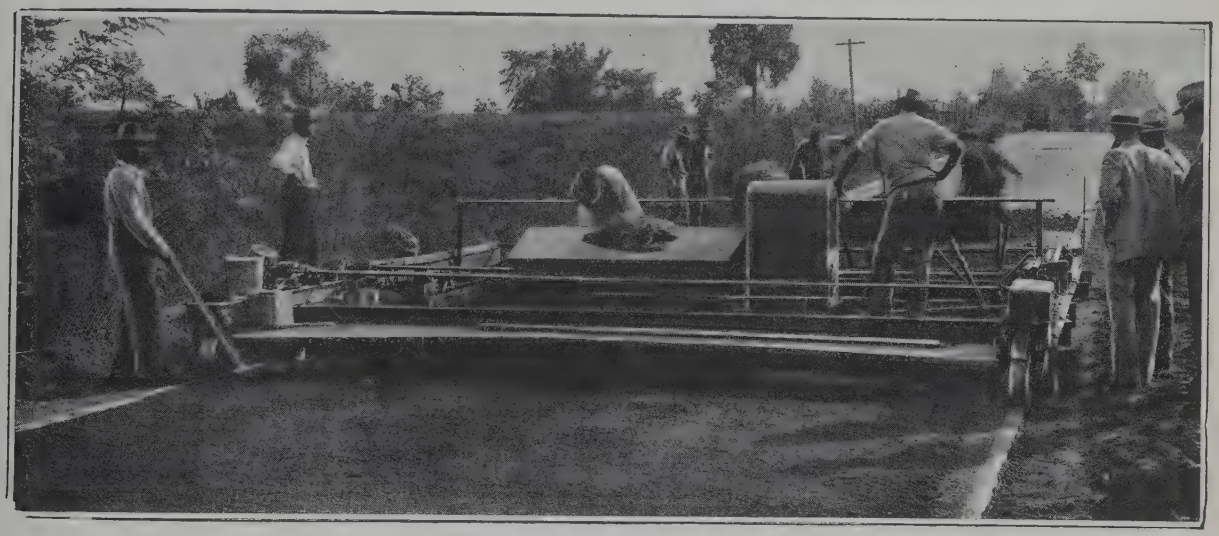

Fig. 1—Rock Asphalt Being Spread with a Concrete Finishing Machine

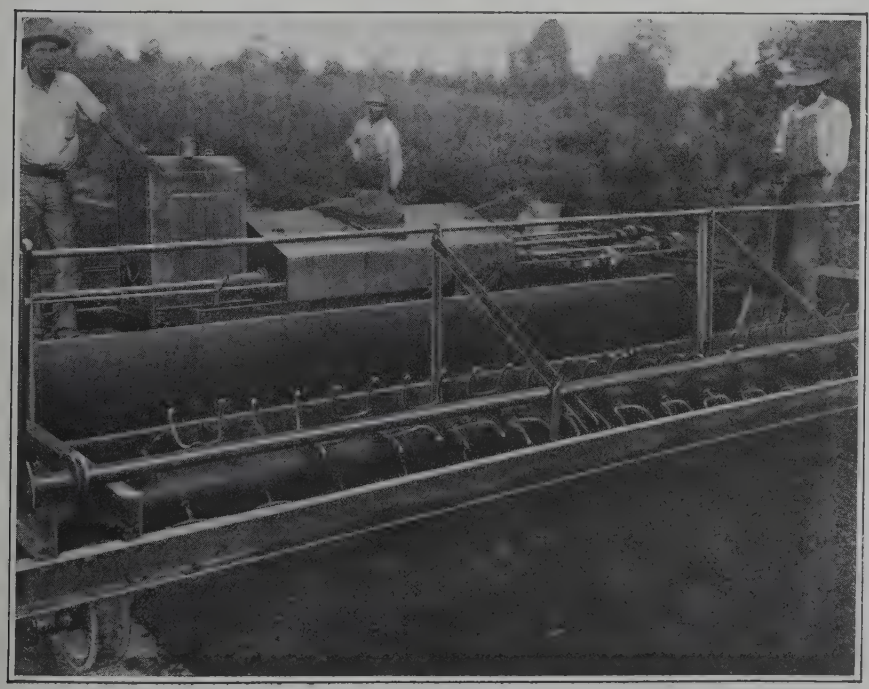

Fig. 2—Close-up View of Rotating Rake Attachment to Finishing Machine

As shown by Fig. 2, a revolving rake is supported by a separate carriage, which is connected loosely to the finishing machine proper. The shaft is driven from the finisher by a sprocket and chain and is rotated at a relatively high speed. The teeth are set in spirals along and around the shaft so as to reach practically every portion of the roadway width. Both the rake carriage and the finishing machine run on the curbs. In finishing, the shoes of the screed are set so that the screed finishes the asphalt ½ in. high to allow compression by the roller. Referring to Fig. 2, the piling up of the asphalt ahead of the screed is to be observed. Its fineness and freedom from lumps compared with the material ahead of the rake is also to be noticed. In Fig. 1 the asphalt as spread by the screed

is shown. This illustration also shows the whole gang of nine men required to spread and finish the asphalt ready for rolling.

This machine finishing is found to have several advantages. It gives a uniform yield in square yards per ton; less than 0.1 sq. yd. per ton variation has been shown. The output compared with raking by hand is about doubled. There is less supervision required by the inspector to make certain that the proper amount of material is being got into the spreads at all times. The labor is cut down; besides the foreman and finishing machine operator, there are only nine men. With this gang an average of 3,000 sq. yd. a day is being surfaced.

This road is on Route No. 1, Memphis to Bristol Highway, and is one of the most important roads in Tennessee. The work is being done by the writer's firm as contractor for the state highway department, whose engineers have expressed appreciation of the exact and satisfactory work of the finishing machine. It is possible that, due to the highly satisfactory results being obtained on this project, the Department of Highways will specify a finishing machine for all jobs of this character in the future.

Financial Statistics of City Governments for 1927

The U. S. Department of Commerce announces a summary of the financial transactions of the 250 cities having a population of over 30,000 for the fiscal year 1927.

The total payments for operation, maintenance, interest, and outlays for permanent improvements for cities having over 30,000 population were 92.5 per cent greater than similar payments of the government of the 48 states, and 0.1 per cent greater than those for the Federal government for the fiscal year 1927.

Preliminary statements for each of the cities have been released for publication as rapidly as the reports were received, the first of these statements appearing Oct. 31, 1927. A summary, by cities, will be available within a few weeks giving financial statistics which will show assessed valuations and tax levies, revenues collected, governmental-cost payments, and indebtedness.

Expenditures.—The payments for operation and maintenance of the general departments of the city governments of the 250 cities for the fiscal period 1927 amounted to $1,750,707,093, or $40.98 per capita. In 1926 the comparative per capita for operation and maintenance of general departments was $39.18, and in 1917, $19.07. Payments for the operation of public service enterprises, as water works, electric light plants, and similar enterprises, amounted to $162,470,940; interest on debt, $319,248,702; and outlays for permanent improvements, including those for public service enterprises, $1,091,959,616. The total payments in 1927, therefore, were $3,324,386,351; in 1926, $3,052,645,496; and in 1917, $1,108,021,565.

The per capita net governmental-cost payments for operation, maintenance, and interest for 146 cities covered by census reports since 1903 were $52.64 in 1927, $50.30 in 1926, $24.58 in 1917, and $16.41 in 1903.

The totals include all payments for the year, whether made from current revenues or from the proceeds of bond issues. Proceeds from the issuance of debt obligations are not considered revenue receipts.

Of the 250 cities covered by this report only two were lacking in revenues sufficient to meet all operating expenses and interest, while 70 realized enough revenues to meet all their payments for expenses, interest, and outlays and to have a balance available for paying debt.

Of the total municipal payments in 1927, 52.7 per cent was for operation and maintenance of general departments; 4.9 per cent, operation and maintenance of public service enterprises; 9.6 per cent, interest on debt; and 32.8 per cent, outlays for permanent improvements.

Of the payments for operation and maintenance of general departments, 38.2 per cent was for education; 20 per cent, protection to person and property; 8.9 per cent, highways; 8.5 per cent, general government; 7.7 per cent, sanitation or promotion of cleanliness; 6.1 per cent, charities, hospitals and corrections; 4.7 per cent, miscellaneous; 3.4 per cent, recreation; and 2.4 per cent, conservation of health.

The percentages for 1927 show but little change from those for 1926, the largest in each of the years being for education and the smallest for conservation of health.

Of the total payments for outlays for permanent improvements, the principal items were $394,963,016, or 36.1 per cent, for highways; $198,560,613, or 18.2 per cent, for education; and $196,317,702, or 17.9 per cent, for public service enterprises.

Revenues.—The total revenue receipts of the 250 cities for 1927 were $2,945,511,729, or $68.96 per capita. This was $713,084,994 more than the total payments of the year, exclusive of the payments for permanent improvements, but $378,874,622 less than the total payments, including those for permanent improvements. The revenue receipts included $1,888,704,574 from general property taxes; $64,457,627 from special taxes; $88,941,226 from licenses; $233,292,693 from special assessments; $144,292,408 from subventions, donations, and pension assessments; $136,454,248 from interest, rents, and highway privileges; $290,941,918 from earnings of public service enterprises; and $98,427,035, the remainder, from poll taxes, fines, forfeits, and escheats, and earnings of general departments.

The per capita net revenue receipts of 146 cities covered by census reports since 1908 were $69.77 in 1927, $66.14 in 1926, $31.97 in 1917, and $21.14 in 1903.

Indebtedness.—The net indebtedness (funded or fixed debt less sinking fund assets) of the 250 cities amounted to $5,479,284.872, or $128.27 per capita, in 1927, this being an increase of 7.0 per cent over that for 1926. The per capita net debt of 146 cities covered by reports since 1903 was $134.27 in 1927, $128.13 in 1926, $80.75 in 1917, and $44.71 in 1903.

While in 1927, as compared with 1926, there was an increase of $361,112,478 in net debt for the 250 cities as a whole, there were 84 individual cities which showed a decrease in their net indebtedness.

A comparison of the aggregate increase in net indebtedness with the total payments for outlays discloses the fact that 33.1 per cent of the permanent improvements for 1927 were financed from proceeds of bond issues.

New Jersey Sewage Works Association Meets in March

The New Jersey Sewage Works Association, the Engineering Bureau of the State Department of Health of New Jersey cooperating, will hold its 14th annual meeting on March 22 and 23, 1929, at the Stacy-Trent Hotel, Trenton, N. J.

The meeting is planned for municipal officials, particularly those connected directly or indirectly with sewers, sewage disposal and allied activities and provides an opportunity for the exchange of information and ideas through the medium of round table discussions. Authorities will present papers on various phases of sanitation, which with the discussions, we believe, will be of practical value to those attending the meeting.

The value of the work which this association has done in the past is attested by the fact that a dozen other states have formed similar associations patterned after the original New Jersey Sewage Works Association. The attendance last year was over 250 from New Jersey and ten other states. John R. Downes, Bound Brook, N. J., is secretary of the New Jersey Sewage Works Association.

Developed Water Power in the United States on Jan. 1, 1929.—The total capacity of water wheels installed in water power plants of 100 hp. or more in the United States on Jan. 1, 1929, was 13,571,530 hp., an increase of 1,275,530 hp., or 10.4 per cent, during 1928. The increase in 1927 was only 575,000 hp. The gain in 1928 was therefore more than twice that during 1927.

Definitions of Terms Used in Sewerage and Sewage Disposal Practice

An Am. Soc. C. E. Manual of Engineering Practice

THE formulation of definitions of terms used in sewerage work was initiated in 1915 by the American Public Health Association. The work was continued by committees of the Association until 1924. In May of that year the Sanitary Engineering Division of the American Society of Civil Engineers appointed a committee on definitions. Joint action between the two societies followed and on Oct. 22, 1924, at a joint meeting of the Sanitary Engineering Division of the American Society of Civil Engineers and the Sanitary Engineering Section of the American Public Health Association, a tentative report based on the work of the two committees was presented. The work was then continued and on Oct. 13, 1927, the joint report of the two committees was adopted by the Sanitary Engineering Division of American Society of Civil Engineers. The American Public Health Association adopted this report on Oct. 20, 1927, and on July 16, 1928, the report was also adopted by the Board of Directors of the American Society of Civil Engineers. The latter society has published recently the list of definitions as one of its manuals of engineering practice.

Definitions of Terms Used in Sewerage and Sewage Disposal Practice

A. B. C. Process (Alum, Blood, Clay).—A method of deodorizing and precipitating sludge by the addition of alum, charcoal, or some other material and clay, to the raw sewage. One of the earliest satisfactory methods of clarification by chemical precipitation.

Activated Sludge.—Sludge settled out of sewage previously agitated in the presence of abundant atmospheric oxygen.

Activated Sludge Method.—See **Activated Sludge Process.**

Activated Sludge Process.—Sewage treatment in which sewage standing in or flowing through a tank is brought into intimate contact with air and with biologically active sludge, previously produced by the same process. The effluent is subsequently clarified by sedimentation.

Aeration.—The process or method of bringing about intimate contact between air and a liquid by allowing finely divided air to pass through the liquid or the finely divided liquid to pass through air.

Air-Lift.—A device for raising sewage or other liquid by injecting air in and near the bottom of an open discharge pipe submerged in a well of the liquid to be raised.

Alignment.—The direction of the axis of a sewer in plan.

Alternating Device.—A device whereby sewage may be automatically delivered into different parallel treatment units in a cycle following a predetermined sequence.

Appurtenances.—See **Sewer Appurtenances.**

Back-Water Gate.—A device for preventing the back flow of sewage or water.

Baffles.—Deflectors of wood, metal, or masonry, placed in flowing liquid to divert, guide, or agitate the flow of such liquid.

Band Screen.—An endless band or belt of wire mesh, bars, plates, or other screening medium, which passes around upper and lower rollers or guides.

Bar Screen.—A screen composed of parallel bars or rods. See, also, **Rack.**

Barn Sewage.—Wash water from stables, considerable quantities of animal wastes.

Basin.—A shallow tank or natural or artificial depression through which liquids pass or in which they are detained for treatment.

Bio-Aeration.—A modification of the activated sludge process in which the sewage and sludge are agitated and aerated by mechanical means, such as paddle-wheels or turbines.

Bio-Chemical Action.—Chemical action resulting from the growth or metabolism of living organisms.

Bio-Chemical Oxygen Demand.—The quantity of oxygen required for bio-chemical oxidation in a given time at a given temperature. the determinations usually being for 5 days at 20° cent.

Biolytic Tank.—A continuous flow tank with hopper bottom, with inlet arranged so as to agitate the sludge by the entry of sewage at the apex of the hopper-shaped bottom. This agitation tank is sometimes followed by a settling tank in which the sludge is detained until removed.

Bleach. — Calcium hypochlorite. (Bleaching Powder.)

Blow-Off.—A waste-gate or device for discharg- accumulated solids or for emptying a depressed sewer.

Branch Sewer.—An arbitrary term for a sewer which receives sewage from a relatively small area.

Branches.—Special forms of vitrified tile and cast-iron pipe for making connections to a sewer. They are called Tee, Y, Tee-Y, Double-Y, and V, from the shapes. (Synonym, Junction Pieces.)

Broad Irrigation.—The disposal of sewage by application to farm land involving the incidental benefit to crops growing out of the irrigation and fertilization resulting from the application of the sewage. (Differs from sewage farming in that the primary purpose is the disposal of sewage while the raising of crops is incidental only.) See, also. **Sewage Farming.**

Cage-Screen.—A screen consisting of a cage, with sides of bars, rods, or mesh, so arranged that it may be lowered into the sewage and raised therefrom for cleaning.

Capillary Water.—Water in the interstices of the soil or of a sand filter, which is not lost by draining.

Catch-Basin.—A chamber or well. designed to prevent the admission of grit and detritus into a sewer.

Catch Pit.—See **Grit Catcher.**

Catchment Area.—The area of a water-shed tributary to a lake, stream or sewer.

Centrifuge.—A device in which sludge is dewatered by rapid rotation and automatically discharged.

Cesspool.—A pit into which household sewage or other liquid waste is discharged and from which the liquid leaches into the surrounding soil, or is otherwise removed.

Chamber.—A general term for a space enclosed by walls or a compartment, often prefixed by a descriptive word as "grit chamber" or "screen chamber" indicating its contents, or "discharge chamber" or "flushing chamber" indicating its office.

Chemical Precipitation.—Sedimentation accelerated by the coagulation of suspended or colloidal matter through the addition of chemicals.

Chlorination.—Treatment with chlorine or bleaching powder for the purpose of disinfection. the retardation of decomposition, or the oxidation of organic matter.

Circumferential Flow.—Flow parallel to the periphery of a circular tank.

Clarification.—The process of removing suspended and colloidal matter from a turbid liquid.

Clarified Sewage.—Loosely used for sewage from which suspended matter has been partly or completely removed.

Coagulation.—The flocculation of colloidal or suspended matter brought about by the addition of some chemical to the liquid, by contact, or by other means.

Coarse-Grained Filter.—General term for contact bed or trickling filter.

Coarse Rack.—A relative term. but generally used when the clear space between bars is 2 in. or more.

Coarse Screen.—A relative term, but generally used when openings are greater than 1 in. in least dimension, except in the case of racks. See, also, **Coarse Rack.**

Coefficient of Imperviousness.—The ratio, expressed decimally, of effectively impervious surface to the total catchment area.

Collecting System.—All sewers from the house to the outfall. See, also, **Sewerage System.**

Colloidal Matter.—Colloids or matter colloidal in character and action.

Colloids.—(1) The finely divided suspended matwhich will not settle and the apparently dissolved matter which may be transformed into suspended matter by contact with solid surfaces or preciptated by chemical treatment. (2) Substances which are soluble as judged by ordinary physical tests, but will not pass through a parchment membrane.

Combined Sewer.—A sewer designed to receive both storm water and sewage.

Combined System.—A system of sewers, in which sewage and storm water are carried in the same conduits.

Commercially Dry Sludge.—Sludge containing not more than 10 per cent of moisture by weight.

Common Sewer.—A sewer in which all abutters have equal rights.

Compartment.—A chamber in. or a division of, a structure for sewage treatment.

Concentrated Sewage.—A relative term. Sewage containing a relatively large quantity of organic matter.

Conditioning.—See **Sludge Conditioning.**

Contact Aerator.—A device consisting of a crate holding broken stone, coke, brushwood, or other media, which is placed in a single, or two-story sedimentation tank and through which the sewage is made to flow upward and return on the outside and become activated by the admission of compressed air below.

Contact Bed.—An artificial bed of coarse material, such as broken stone or clinkers, in a water-tight basin provided with controlled inlet and outlet. It is operated in cycles of filling with sewage, standing full in contact, emptying, and resting empty, in order to remove some of the suspended matter and oxidize organic matter by bio-chemical agencies.

Contaminated Water.—Water unfit for any given use because of contact with or the presence of injurious substances.

Contamination.—The introduction into water, otherwise satisfactory, of bacteria, sewage, or other substance, which makes it unfit for any given use.

Cover.—See **Manhole Head.**

Crown.—The inside top of a sewer.

Crude Sewage.—Sewage which has received no treatment.

Datum.—Plane of reference for elevations.

Degreasing.—The process of removing fats and greases from sewage, waste, or sludge.

Degree of Purification.—A measure of the removal and oxidation of the objectionable or putrescible contents of sewage.

Depressed Sewer.—A sewer, often crossing beneath a valley or a water course, which runs full or under greater than atmospheric pressure because its profile is depressed below the hydraulic grade line.

Detritus Tank or Chamber.—A detention chamber larger than a grit chamber, usually with provision for removing the sediment without interrupting the flow of sewage. A settling tank of short detention period designed, primarily, to remove heavy settleable solids.

Diffuser.—A porous plate or other device through which air is forced and enters the sewage in the form of minute bubbles.

Digestion.—The bio-chemical decomposition of organic matter resulting in the formation of mineral and simpler organic compounds.

Dilute Sewage.—A relative term. Sewage containing a relatively small quantity of organic matter.

Dilution.—(1) A method of disposing of sewage or effluent by discharging into a stream or other body of water. (2) The ratio of the volume of flow of a stream to the volume of sewage or effluent discharged into it.

Direct Oxidation Process.—(So-called.) A proprietary method of treatment in which sewage previously dosed with lime is passed through closed tanks between plate electrodes across which electric current is passing while the liquid is agitated by rotating paddles.

Disc Screen.—A screen in the form of a circular disc rotating about an axis perpendicular to its center.

Discharge Sewer.—See **Outlet Pipe.**

Disinfected Sewage.—Crude sewage, or a sewage plant effluent which has been treated with a disinfecting agent, commonly chlorine or "bleach," resulting in the destruction of bacteria sufficiently to reduce materially the danger of infection.

Disinfection.—The partial destruction, ordinarily by the use of some chemical, of the microorganisms likely to cause infection and disease.

Dispersion.—A method of disposal of the suspended solids in sewage or effluent by scattering them widely in a stream or other body of water.

Distributor.—A device used to apply sewage to the surface of a filter. There are two general types, fixed and movable. The fixed type may consist of perforated pipe or notched troughs, sloping boards, or sprinkler nozzles. The movable type may consist of rotating or reciprocating perforated pipes or troughs applying spray or a thin sheet of sewage.

Diversion Chamber.—A chamber which contains a device for diverting all or a part of the flow.

Diversion Manhole.—See **Diversion Chamber.**

Domestic Sewage.—Sewage derived principally from dwellings, business buildings, institutions, and the like. (It may or may not contain ground-water, surface water, or storm water. It may also contain a small proportion of industrial waste liquid.)

Door Thickener.—(Clarifier.) A proprietary device placed in a tank by which a system of scrapers, driven by a central shaft, revolves slowly, pushing the deposited sludge to a central outlet, from which it is removed by gravity or pumping.

Dortmund Tank.—A vertical-flow sedimentation tank with hopper bottom. The sewage, introduced near the bottom, rises and overflows at the surface, and the sludge may be removed from the bottom before it becomes septic.

Dosing Chamber.—See **Dosing Tank.**

Dosing Siphon.—An automatic siphon for discharging the contents of a dosing tank.

Dosing Tank.—A tank into which raw or partly treated sewage is introduced and held until the desired quantity has been accumulated, after which it is discharged at such a rate as may be necessary for distribution essential to the subsequent treatment.

Drain.—Conduit or pipe, usually underground, for carrying off, by gravity, liquids other than sewage and industrial wastes, and including ground or subsoil water, surface water, and storm water.

Drainage.—A general term for gravity flow of liquids in conduits. Commonly applied to surface and ground-water.

Drainage System.—A system of drains.

Drainage Water.—Water flowing in a drain derived from ground, surface or storm water.

Drop Manhole.—A shaft in which sewage falls from a sewer to a lower level.

Drum Screen.—A screen in the form of a cylinder or truncated cone rotating on its axis.

Dry-Weather Flow.—Flow of sewage in a sewer during dry weather.

Effluent.—Sewage, partly or completely treated, flowing out of any sewage treatment device.

Effluent Discharge Conduit.—See **Outlet Pipe.**

Ejector.—See **Pneumatic Ejector.**

Emscher Filter.—See **Contact Aerator.**

End Manhole.—One at the up-stream end of a sewer.

Entrance Well.—See **Inlet Well.**

Evaporation.—Vaporization of moisture from a wet surface.

Filtered Sewage.—The effluent of a sewage filter.

Filtering Medium.—The material through which sewage applied to a filter must pass.

Filtration.—(1) The process of removing suspended and colloidal matter from a liquid and the oxidation of its dissolved organic matter, by causing it to flow through a relatively fine porous medium. (2) Sometimes loosely applied to the removal of solids and liquid organic matter in treatment beds.

Filtros.—The trade name applied to an artificial porous stone made of carefully graded silicious sand by moulding, pressing, firing, annealing, and grinding. It is used as a filtering medium and for diffusing air in the activated sludge process.

Final Settling Basin.—A tank through which the effluent of a trickling filter, or other oxidizing device, passes for the purpose of removing the settleable solids before its discharge.

Final Settling Tank.—Same as final settling basin, but deeper and of less area.

Fine Rack.—A relative term, but generally used when the clear space between the bars is 1 in. or less.

Fine Screen.—A relative term, but generally used for a screen with openings ¼ in., or less, in least dimension.

Flaring Inlet.—A funnel-shaped entrance to facilitate flow into a pipe or conduit.

Flotation.—A method of collecting suspended matter in a tank as a scum at the surface by the evolution of gas by chemicals, electrolysis, heat, or bacterial decomposition.

Flowing-Through Chamber.—The upper compartment of a 2-story sedimentation tank.

Flush Tank.—A chamber in which water or sewage is accumulated and discharged at intervals for flushing a sewer.

Flushing Chamber.—See **Flush Tank; Flushing Manhole.**

Flushing Manhole.—A manhole provided with a gate so that sewage or water may be accumulated and then discharged rapidly for flushing a sewer.

Frame.—See **Manhole Head.**

Fresh Sewage.—Sewage of recent origin still containing free dissolved oxygen.

Gas Slot.—See **Gas Vent.**

Gas Vent.—(1) A passage to permit the escape of gases of decomposition. (2) An opening which allows gas, liberated in an Imhoff tank sludge digestion chamber, to reach the atmosphere without passing up through the sewage in the settling chamber.

Grade.—Elevation of invert.

Gradient.—See **Slope.**

Grating.—A screen consisting of parallel bars, two sets being transverse to each other in the same plane.

Gravity System.—A system in which all sewage runs on descending gradients from source to outlet, or where no pumping is required.

Grease Trap.—A device by means of which the grease content of sewage is cooled and congealed so that it may be skimmed from the surface.

Grit.—The heavy mineral matter contained in sewage, such as sand, gravel, cinders, etc.

Grit Catcher.—A chamber usually placed at the upper end of a depressed sewer, or at other points of protection on combined or storm-water sewers, of such shape and dimensions as to reduce the velocity of flow and thus permit the settling out of grit.

Grit-Chamber.—A small detention chamber or an enlargement of a sewer designed to check the velocity of the sewage enough to permit the heaviest solid matter, such as grit, to be deposited with a view to its frequent and easy removal. (Grit Compartment.)

Ground-Water—Water derived from beneath the surface of the ground.

Ground-Water Drain.—A drain which carries away ground-water.

Horizontal Flow Tank.—A tank or basin, with or without baffles, in which the direction of flow is generally horizontal.

House Connection.—See **House Sewer.**

House Sewage.—(1) Sewage from dwellings. (2) Loosely used for domestic sewage.

House Sewer.—A pipe conveying the sewage from a single building to a common sewer or point of immediate disposal.

Humus Sludge.—(1) Digested sludge deposited in final or secondary settling tanks, following trickling filters or other oxidizing device. (2) Sludge resembling humus in appearance.

Humus Tank.—A tank for collecting humus sludge. See, also, **Final Settling Tank; Final Settling Basin.**

Hydraulic Grade.—The elevation of the surface of the liquid in a sewer above an assumed datum.

Hydraulic Gradient.—The surface slope of the liquid in a sewer. Generally taken parallel to the invert.

Hydraulic Inclination.—See **Hydraulic Gradient.**

Hydraulic Slope.—See **Hydraulic Gradient.**

Hydrolysis.—A change in the molecular composition of matter produced by the addition of water.

Hydrolytic Tank.—In general, any sewage tank in which hydrolysis occurs, specifically applied to a special form of vertical flow tank. General term for any sedimentation tank in which, by bio-chemical processes, a part of the suspended organic matter is liquefied and gasified.

Imhoff Tank.—A deep two-storied tank invented by Karl Imhoff, M. Am. Soc. C. E., consisting of an upper or continuous sedimentation chamber and a lower or sludge digestion chamber. The floor of the upper chamber slopes steeply to trapped slots, through which solids may settle into the lower chamber. The lower chamber receives no fresh sewage directly, but is provided with gas vents and with means for drawing digested sludge from near the bottom.

Industrial Sewage.—Sewage in which industrial wastes predominate. See, also, **Domestic Sewage; Industrial Wastes.**

Industrial Wastes.—Liquid wastes from industrial processes.

Infected Water.—Water which contains pathogenic bacteria.

Infection of Water.—The introduction of pathogenic bacteria into water in sufficient quantities to produce disease.

Infiltration.—The leaching of water from the ground into a sewer.

Influent.—Sewage, raw or partly treated, flowing into any sewage treatment device.

Inlet.—A connection between the surface of the ground and a sewer for the admission of surface or storm water.

Inlet Well.—A well or opening at the surface of the ground to receive surface water which is thence conducted to a sewer.

Institutional Sewage.—Domestic sewage from institutions, such as hospitals, sanitariums, or penal and charitable establishments.

Intercepting Sewer.—A sewer which receives the dry-weather flow from a number of transverse sewers or outlets, with or without a determined quantity of storm water if from a combined system.

Intermittent Filter.—A natural or artificial bed of sand or other fine-grained material to which sewage is intermittently applied in doses and through which it flows, opportunity being given for filtration and also oxidation of the organic matter by bio-chemical agencies.

Invert.—Originally, the inverted arch of a masonry-lined sewer. By derivation, the floor, bottom, or lowest point in the internal cross-section of a sewer.

Invert Block.—A voussoir-shaped hollow tile built into the invert of a masonry sewer.

Inverted Siphon Sewer.—See **Depressed Sewer.**

Irrigation.—See, **Sub-Surface Irrigation; Surface Irrigation; Broad Irrigation; Sewage Farming.**

Junction Chamber.—A converging section of a sewer used to facilitate the flow from one or more sewers into a main sewer.

Junction Manhole.—A manhole at the junction of two or more sewers.

Kitchen Waste.—Liquid culinary wastes.

Lamp-Hole.—A small vertical pipe or shaft leading from the surface of the ground to a sewer, for admitting a light for purposes of inspection.

Land Drain.—A drain for drawing off water from land. See, also, **Ground-Water Drain.**

Lateral Sewer.—A sewer which discharges into a branch or other sewer and has no other common sewer tributary to it.

Leaching Cesspool.—A cesspool out of which the liquid leaches into the surrounding soil.

Line Manhole.—A manhole in the line of a sewer at a point where no other sewers connect. It may be at a point where the sewer changes direction, either in line, slope, or grade.

Liquid Sludge.—Sludge containing sufficient water to permit it to flow by gravity (ordinarily above 80 per cent).

MacLachlan Process.—(A Proprietary Process.) A method of conditioning sludge preparatory to dewatering by the application of sulfur dioxide gas.

Main Sewer.—A sewer which receives one or more branch sewers as tributaries.

Manhole.—A shaft, or chamber, from the surface of the ground to a sewer, large enough to enable a man to have access for the purpose of inspection and cleaning.

Manhole Head.—The cast-iron fixture surmounting a manhole. It is made up of two parts: A "Frame" which rests on the masonry of the shaft, and a removable "Cover." Frames are either "Fixed" or "Adjustable" in height. Covers are "Tight," "Ventilated," or "Anti-Rattling."

Medium Screen.—A screen having openings intermediate between those of a coarse and a fine screen.

Mesh Screen.—A screen composed of woven fabric, usually of wire.

Miles Acid Process.—A proprietary method of treatment invented by George W. Miles, in which sewage is acidified by sulfurous acid fumes. The fumes are absorbed by a part of the sewage. This part is then mixed with the remainder of the sewage. Subsequent precipitation of solids results in clarification and a measure of disinfection.

Outfall Sewer.—A sewer which receives the sewage from the collecting system and conducts it to a point of final discharge or to a disposal plant.

Outlet Pipe.—A pipe which conveys the effluent from a treatment plant to its final point of disposal.

Oxidation.—See **Sewage Oxidation.**

Oxidized Sewage.—Sewage in which the organic matter has been combined with oxygen and has become stable.

Percolating Filter.—See **Trickling Filter.**

Percolation.—The flow or trickling of a liquid downward through a relatively coarse filtering medium. The liquid usually does not fill the pores of the medium.

Plate Screen.—A screen composed of one or more perforated plates.

Pneumatic Ejector.—A means of raising sewage, or other liquid, by alternately admitting it through a check-valve into the bottom of a pot and then ejecting it through another check-valve into the discharge pipe, by admitting compressed air to the pot above the liquid.

Polarite.—Magnetic spongy carbon, formerly used as a filter medium after sedimentation.

Polluted Water.—Water made unclean or injured by sewage, industrial waste, or other substance.

Pollution.—The act of making unclean or impure or the state of being unclean or impure as a result of admixtures of sewage, industrial wastes, or other substance.

Precipitation.—Rain and snowfall. See, also, **Chemical Precipitation.**

Private Sewer.—One privately owned and used by one or more properties.

Public Sewer.—A common sewer controlled by public authority.

Putrefaction.—Biological decomposition of organic matter with the production of ill-smelling products. It occurs under conditions of oxygen deficiency.

Putrescibility.—(1) The susceptibility of waste waters, sewage, effluent, or sludge to putrefaction. (2) The relative tendency of organic matter to undergo decomposition in the absence of oxygen.

Rack.—A screen composed of parallel bars, either vertical or inclined, from which the screenings may be raked.

Radial Flow.—Direction of flow across a circular tank, from center to periphery, or vice versa.

Radial Inward Flow.—Inlet at periphery and outflow at the center of a circular tank.

Radial Outward Flow.—Inlet at center and outflow at the periphery of a circular tank.

Rainfall Rate.—Precipitation, generally expressed in inches per hour.

Rate of Precipitation.—See **Rainfall Rate.**

Raw Sewage.—See **Crude Sewage.**

Receiving Basin.—See **Inlet Well.**

Regulator.—A device for controlling the quantity of sewage admitted to an intercepting sewer or unit of a disposal plant.

Relative Stability.—The ratio, expressed in percentage, of available oxygen in waste waters, sewage, effluent, or diluted sewage to that required to provide complete bio-chemical oxidation of the organic matters contained therein.

Relief Sewer.—A sewer built to relieve an existing sewer of inadequate capacity.

Reservoir.—A tank or basin primarily for storage of a liquid.

Roof Water.—Storm water from roofs.

Run-Off.—That part of the rainfall which reaches a stream, drain, or sewer.

Run-Off Coefficient.—The ratio, expressed decimally, of run-off to precipitation.

Run-Off Rate.—An expression of the rate at which rainfall runs off from a surface, expressed in inches in depth of rainfall per hour, cubic feet per second, or other units.

Sand Catcher.—See **Grit Catcher.**

Sand Filter.—A filter in which sand is the filtering medium. See, also, **Intermittent Filter.**

Sanitary Sewage.—(1) Domestic sewage with storm water excluded by design. (2) Sewage originating in the sanitary conveniences of a dwelling, business building, factory, or institution. (3) The water supply of a community after it has been used and discharged into a sewer.

Sanitary Sewer.—A sewer which carries sewage and excludes storm, surface, and ground-water.

Saturation.—The condition of a liquid when it has taken into solution the maximum possible quantity of a given substance at a given temperature and pressure, as water saturated with oxygen.

Screen.—A device with openings, generally of uniform size, used to retain coarse sewage solids. The screening element may consist of parallel bars, rods, or wires, grating, wire mesh, or perforated plate, and the openings may be of any shape, generally circular or rectangular slots.

Screening.—The removal of relatively coarse floating and suspended solids by straining through racks or screens made of bars, gratings, wires, or perforated plates.

Screenings.—Material removed from sewage by screens and racks.

Scum.—A mass of sewage solids, buoyed up by entrained gas, grease, or other substance, which floats at the surface of sewage.

Scum Board.—A vertical baffle dipping below the surface of sewage in a tank to prevent the passage of floating matter.

Secondary Settling Tank.—See **Final Settling Tank.**

Sedimentation.—The subsidence and deposition of suspended matter in a liquid by gravity.

Sedimentation Tank.—A tank or basin in which sewage, partly treated sewage, or other liquid containing settleable solids, is retained long enough, and in which the velocity is low enough, to bring about sedimentation of a part of the suspended matter, but without a sufficient detention period to produce anaerobic decomposition.

Semi-Circumferential Flow.—Flow parallel to the semi-circumferences of a circular tank, divided at the inlet and meeting again at the common outlet.

Separate Sludge Digestion.—The digestion of sludge in basins or tanks to which it is removed from the basins or tanks in which it originally settled.

Separate System.—A system of sewers in which sewage and storm water are carried in separate conduits.

Sept-Aer-Sed Method.—Sewage treatment in which septic tank effluent is aerated and passed into a sedimentation tank. The sludge from the sedimentation tank is then pumped back into the septic tank.

Septic Sewage.—Sewage undergoing putrefaction in the absence of oxygen.

Septic Tank.—A settling tank intended to retain the sludge in immediate contact with the sewage flowing through the tank for a sufficient period to secure a satisfactory decomposition of organic solids by anaerobic bacterial action.

Settleable Solids—Suspended solids which will subside in quiescent sewage in a reasonable period. (Two hours is a common arbitrary period.)

Settled Sewage.—Sewage from which some of the solids have settled out in a tank during quiescence or slow flow.

Settling Chamber.—(1) The second or final element of the so-called biolytic tank. (2) Sometimes used to designate the sedimentation compartment of a 2-story tank, as in the case of the Imhoff tank. See, also, **Sedimentation Tank.**

Settling Solids.—See **Settleable Solids.**

Settling Tank.—See **Sedimentation Tank.**

Sewage.—(1) Wash water and water-carried animal, culinary, and, in some cases, industrial wastes. (2) Liquid waste containing human excreta, and other matter, flowing in or from a house drainage system or sewer. Excreta include feces, urine, secretion from the skin, expectoration, etc. (3) Liquid wastes from dwellings and institutions, stables, and business buildings. It may also contain liquid wastes from industries. (4) A combination of (a) the liquid wastes conducted away from residences, business buildings, and institutions, and (b) from industrial establishments, with (c) such ground, surface, and storm water as may be admitted to or find its way into the sewers. (5) The ordinary liquid contents of a sewer containing organic wastes, which may or may not include street wash.

Sewage Disposal.—General term. The act of disposing of sewage by any method.

Sewage Farming.—A term applied to the raising of crops where sewage is applied to the land for irrigation and fertilization purposes. See, also, **Broad Irrigation.**

Sewage Oxidation.—The process whereby, through the agency of living organisms in the presence of oxygen, the organic matter is converted into a more stable or mineral form.

Sewage Purification.—(1) The removal or mineralization of all putrescible organic matter and the removal of all infectious and offensive matter. (2) Loosely used for Sewage Treatment.

Sewage Treatment.—Any artificial process to which sewage is subjected in order to remove or so alter its objectionable constituents as to render it less offensive or dangerous.

Sewage Treatment Works.—Treatment plant and means of disposal.

Sewer.—A pipe or conduit, generally closed, but normally not flowing full, for carrying sewage and other waste liquids.

Sewer Appurtenances.—Constructions, devices and appliances other than the pipe or conduit, which are appurtenant to a sewer, such as manholes, flush tanks, surface inlets, etc.

Sewer Arch.—The curved top of a masonry sewer.

Sewer Outfall.—The structure at the lower end of an outfall sewer.

Sewer District.—The area deemed benefited by the construction and use of sewers.

Sewer Inlet.—See **Inlet Well.**

Sewer Territory.—See **Sewer District.**

Sewerage System.—A collecting system of sewers and appurtenances.

Sewerage Treatment Works.—See **Sewage Treatment Works.**

Sewerage Works.—Comprehensive term, including all construction for collection, transportation, pumping, treatment, and final disposition of sewage.

Sheffield System.—A method of activating sludge by the rotation of paddle-wheels placed at intervals in a long and relatively narrow and shallow tank.

Side-Walls.—The vertical, curved, or inclined walls which support the arch or top of a masonry sewer.

Simplex Process.—A process for activating sludge by the circulation of sewage up through a central tube, dispersing it by the rotation of an inverted cone suspended above, and permitting a downward return outside the tube.

Sink Water.—Liquid waste from a sink.

Skimming Tank.—A chamber so arranged that floating matter rises and remains on the surface of the sewage until removed while the liquid flows out continuously under partitions, curtain-walls, or scum boards.

Slant.—A branch inserted in a sewer for the purpose of making connection thereto.

Sleek.—The thin oily film usually present which gives characteristic appearance to the surface of water into which sewage or oily waste is discharged.

Slope.—The inclination of the invert of a sewer expressed in percentage of length, as a decimal, or as 1-ft. fall in a given length of feet.

Slot.—A narrow opening.

Sludge.—The accumulated suspended solids of sewage deposited in tanks or basins, mixed with more or less water to form a semi-liquid mass.

Sludge Bed.—Natural or artificial layers of porous material upon which sludge is dried by drainage and evaporation.

Sludge Cake.—A mass resulting from sludge pressing, or vacuum filtering.

Sludge Chamber.—See **Sludge Digestion Chamber.**

Sludge Compartment.—See **Sludge Digestion Chamber.**

Sludge Concentration.—Any process of reducing the water content of sludge which leaves it still in a liquid condition.

Sludge Conditioning.—Treatment of liquid sludge preliminary to, and to facilitate, de-watering.

Sludge De-Watering.—A general term for the removal of a part of the water in sludge by any process, such as draining, pressing, centrifuging, exhausting, passing between rollers, or acid flotation, with or without heat. It involves reducing from a liquid to a spadable condition rather than merely changing the density of the liquid (concentration) on one hand, or drying (as in a kiln) by high heat on the other.

Sludge Digestion.—The bio-chemical process by which organic matter in sludge is gasified, liquefied, mineralized, or converted into more stable organic matter.

Sludge Digestion Chamber.—(1) Any chamber used for the digestion of sludge. (2) The lower story of an Imhoff tank or Travis tank.

Sludge Drying.—The process of drying sludge by drainage or evaporation, by exposure to the air, or by application of heat.

Sludge-Drying Bed.—See **Sludge Bed.**

Sludge Pressing.—The process of de-watering sludge by subjecting it to pressure, the solids being retained, usually by a cloth fabric through which the water passes.

Spadable Sludge.—Sludge dry enough to be shoveled from the drying bed. (Ordinarily under 70 per cent moisture.)

Spiral Flow Tank.—A tank used in carrying out the activated sludge process in which a spiral motion is given to the sewage in its flow through the tank by the introduction of air through a line of diffusers placed on one side of the bottom.

Spray Nozzle.—See **Sprinkler Nozzle.**

Spraying Nozzle.—See **Sprinkler Nozzle.**

Sprinkler.—See **Sprinkler Nozzle.**

Sprinkler Nozzle.—A nozzle used for applying sewage in the form of a spray to a trickling filter.

Sprinkling Filter.—A trickling filter in which the sewage is applied by spray.

Squeegee.—A device, generally with a soft rubber edge, used for dislodging and removing deposited sewage solids from the walls and bottoms of settling tanks.

Stability.—The ability of any substance, such as sewage, effluent, or digested sludge, to resist putrefaction. (Antonym, Putrescibility.)

Stable Effluent.—A treated sewage which contains enough oxygen to satisfy its oxygen demand.

Stale Sewage.—Sewage containing little or no oxygen, but as yet free from putrefaction.

Stench Trap.—A flap in a frame which opens to admit cellar drainage to a sewer and then closes to prevent sewer air from entering the house.

Sterilization.—The destruction of all micro-organisms ordinarily through the agency of heat or of some chemical.

Sterilized Sewage.—A sewage effluent in which all micro-organisms have been destroyed.

Storm Drain.—See **Storm Sewer.**

Storm Overflow.—A weir, orifice, or other device for permitting the discharge from a combined sewer of that part of the flow in excess of that which the sewer is designed to carry.

Storm Overflow Sewer.—A sewer used to carry the excess of storm flow from a main or intercepting sewer to an independent outlet.

Storm Sewage.—Liquid flowing in sewers during or following a period of rainfall and resulting therefrom.

Storm Sewer.—A sewer which carries storm and surface water, street wash, and other wash waters, or drainage, but excludes sewage.

Storm Water.—Excess water during rainfall or continuously following and resulting therefrom.

Storm-Water Drain.—See **Storm Sewer.**

Storm-Water Overflow.—See **Storm Overflow.**

Storm-Water Overflow Sewer.—See **Storm Overflow Sewer.**

Street Sewer.—Common sewer or public sewer in a street. See, also, **Common Sewer: Public Sewer.**

Strong Sewage.—Sewage containing above the normal quantity of organic matter.

Sub-Drain.—A drain built beneath a sewer to intercept ground-water and prevent it from entering the sewer, especially during construction.

Sub-Grade.—The elevation of the bottom of a trench in which a sewer or drain is laid.

Sub-Main Sewer.—An arbitrary term for relatively large branch sewers.

Subsiding Basin.—See **Sedimentation Tank.**

Subsoil Drain.—A land drain deep enough to take water from the subsoil.

Sub-Surface Irrigation.—The process of sewage treatment in which sewage or effluent is applied to land by distributing it beneath the surface through open jointed pipes or drains.

Surface Inlet.—See **Inlet Well.**

Surface Irrigation.—The process of sewage irrigation in which sewage is applied to and distributed over the surface of the ground.

Surface Water.—Water which flows upon or over the surface of the ground.

Surface-Water Drain.—A drain which carries surface water.

Suspended Matter.—Solids physically suspended in sewage or effluent.

System of Sewerage.—See **Sewerage System.**

System of Sewers.—See **Sewerage System.**

Tank.—Any artificial receptacle through which liquids pass or in which they are detained during collection or treatment.

Tight Cesspool.—See **Water-Tight Cesspool.**

Tight Manhole Cover.—A manhole cover without openings.

Trade Wastes.—British expression for industrial wastes. See, also, **Industrial Wastes.**

Trap.—A device to prevent sewer air from backing up and escaping through a plumbing fixture. When made of cast iron or vitrified tile, it may be of various forms defined as running trap, P-trap, S-trap, etc.

Trash.—The material removed from combined and storm-water sewers by coarse racks.

Travis Tank.—A two-story hydrolytic or septic tank invented by Dr. Travis, consisting of an upper sedimentation chamber with steeply sloping bottom terminating in slots through which the deposited solids pass into a lower or sludge digestion chamber through which latter a predetermined part of the sewage is allowed to pass for the purpose of seeding and maintaining bacterial life in the sludge and carrying away decomposition products. This is for the purpose of inducing digestion of the sludge attended by its reduction in volume.

Treated Sewage.—Sewage which has received more or less complete treatment.

Trickling Filter.—An artificial bed of coarse material, such as broken stone, clinkers, slate, slats, or brush, over which sewage is distributed and applied in drops, films, or spray, from troughs or drippers, moving distributors, or fixed nozzles, and through which it trickles to the under-drains giving opportunity for organic matter to be oxidized by bio-chemical agencies.

Trunk Sewer.—A sewer which receives many tributary branches and serves as an outlet for a large territory. See, also, **Main Sewer.**

Twin or Multiple Dosing Tanks.—Twin or multiple tanks of equal capacity, each equipped with a dosing device, which devices are usually so inter-connected that they fill and discharge alternately, or in rotation.

Under-Drain.—A land drain laid below the surface of the ground, or of a sand filter or sludge bed. See, also, **Sub-Drain.**

Ventilated Manhole Cover.—A manhole cover with openings.

Vertical Flow Tank.—A sedimentation tank in which the sewage enters near the bottom, rises vertically, and flows out at the top.

Water-Tight Cesspool.—A cesspool with tight walls to prevent leaching and from which the contents are removed at intervals.

Weak Sewage.—See **Dilute Sewage.**

Wing Screen.—A screen in which the screening elements are radial planes or curved vanes rotating on a horizontal axis.

Method of Cleaning 37 Year Old Infiltration Gallery

During March and April, 1927, the wooden infiltration gallery, which was built in 1890 and used continuously for the subsequent 37 years as a main source of supply for the city of Newton, Mass., was scraped and thoroughly cleansed of growths and sediment. How this work was handled is described by William P. Morse, City Engineer, in his annual report for 1927.

During the time of cleaning the pumps at the Needham St. pumping station were shut down and all the water used in the city was taken by the Ward St. auxiliary station from the Metropolitan supply.

At two of the manholes, pumps were installed, pumping directly from the gallery and discharging into the river, by which means the ground water in the territory was lowered to grade 82.00, enabling the men to enter the gallery for the work of cleaning, the floor of the gallery being grade 81.00. The normal grade of the ground water outside the gallery was about 87.00. The grade of the Charles River is from 91.00 to 93.00.

The scraping down of the inside of the gallery was done by use of hoes with handles cut off to about 1 ft. in length and other types of scrapers and the materials thus removed, after falling into the 12 in. of water left upon the smooth plank floor was pushed by pushers or squeegees to the pumps and the whole pumped out into the river.

The materials found upon the sides, roof and floor of the gallery had been accumulating for 37 years and consisted of growths and deposits caused largely by crenothrix. These masses of material were found clinging to the roof and side walls of the gallery, forming a coating of from 2 to 6 in. in thickness, much of which, however, had fallen to the floor as the water was lowered by the pumping. The texture of the material was such as to permit of its being held in suspension in the water, and the masses disintegrated upon the slightest agitation. A grayish tinge seemed to be the predominating color.

This material was scraped off and the spruce and hemlock of which the gallery is built was found to be sound.

Manganese is also present in the ground water in the form of a mineral salt. Large quantities of a sand-like material composed of particles so very fine as to blow away in dust when dried, was found upon the floor in large lumps and coal black in color.

Very few of the tube wells which are connected into the gallery were found to be flowing.

The work inside the gallery was necessarily done under unfavorable conditions, but done in a very thorough and effective manner. The gallery is on a level grade and is 4 ft. square in the clear, inside, and about 3,800 ft. long, and is from 10 to 15 ft. underground.

The men were equipped with waist high duck hunter's rubber boots, oilskin coat and hat and a flashlight in addition to their scraping tools. As the water was maintained in the gallery at about 1 ft. in depth, there was left but 3 ft. of space in which to work. This naturally slowed down the work of cleaning somewhat.

Two electrically driven centrifugal pumps were used to hold the ground water down to this level, an 8-in. and a 10-in., with their suctions at the bottoms of the manholes. The manholes were built to a slightly lower level than the floor of the gallery.

Cement Gun Contractors Meet

The second annual meeting of the Cement Gun Contractors' Association was held at the Palmer House, Chicago, Feb. 18, 19 and 20.

Besides the election of officers for the ensuing year, important steps were taken for the improvement of the industry. A movement was started for the unification of the many patents covering various mechanical details and processes involved in Cement Gun work. When perfected, this will enable members of the association to give positive guarantees against patent infringement suits and it will so operate as to place a premium on quality instead of mere cheapness.

Steps were also taken to discourage unfair practices in bidding among members and to stop the practice among general contractors of shopping bids or of beating down Cement Gun prices after bids have been opened and contracts let.

Thirsty Rat Taps Water Pipe

A bill of $49.80 was recently paid by a cooperator of the Biological Survey of the U. S. Department of Agriculture for repairing the damage caused by one rat and its family. It was first noticed that water was dripping from the ceiling of a room directly under the bathroom, and then more than a square yard of plastering came down. The plumber who was called in had to move the bathtub and take up the floor to locate the trouble. He found that a rat had gnawed a hole about a quarter of an inch in diameter in the lead water pipe near the trap, apparently to quench its thirst. The constant drip from this little hole ruined the ceiling below. The householder invested immediately in a box of barium carbonate and a rat trap, and no more traces of rats have been found since this expensive visitation. The Biological Survey states that it is not at all an uncommon occurrence for rats to gnaw lead pipes or when thirsty to go long distances to get water.

Intakes in Lake Ontario for Water Supply of Hamilton, Ont.

Construction Features of New 60-In. Intake

By H. S. PHILIPS and JAMES STODART
City Engineer's Office, Hamilton, Ont.

THE city of Hamilton takes its water supply from Lake Ontario, and by means of a pumping plant forces it five miles to the center of the city. It is distributed over 8,800 acres to a present population of 134,500, and by further pumping is raised to two additional levels.

The annual consumption for 1927 was 6,420,691,500 gal. This represented an average per capita consumption of 138 gal. In the year 1913, the annual consumption was 3,661,893,300 gal. with a consumption of 99.5 gal. per head per day.

The waterworks system of the city of Hamilton was originated in 1859, and took its supply at that time from a rectangular excavation, (now 3,000 ft. long), parallel with the shore of the lake, referred to on the plans as the "infiltration basins," and connected to a pumping station, 1,900 ft. distant, by a 33-in. diameter wood stave conduit.

The rate of inflow by filtration gradually diminished, and in 1889 a 20-in. diameter cast iron intake pipe with wooden crib was laid from the basins 880 ft. into the lake, the depth of water at the inlet being 20 ft.

To provide for increased water consumption, the size of the infiltration basins was increased in 1901. At that time a 36-in. diameter wood stave pipe was laid from the interior of the basins to the lake shore line. This was intended for future extension into the lake, but was never utilized.

In 1913, a 48-in. diameter steel intake was laid 2,144 ft. into the lake, the depth of water over the crib inlet being 33 ft. A 48-in. diameter concrete conduit was also laid to convey the water from the basins to the pump house.

In February 1923, a short but almost total interruption to the city water supply occurred when the flow in the 48-in. diameter intake was blocked by ice. To reduce the risk from further ice trouble, and to provide greater intake capacity, a new 60-in. diameter intake and conduit was recommended in 1926. It was also recommended that the infiltration basins be abandoned and the 48-in. intake and 48-in. conduit joined up. As the intake and conduit entered and left the basins 1,200 ft. apart, the construction of the 48-in. connecting conduit became a major operation.

No trouble has been experienced at Hamilton with the intake pipes on account of scour or deposits on the lake bottom. The 48-in. intake was inspected by divers in August 1923, and from their report everything checked up with conditions as known to exist when the pipe and crib were laid in 1913. Soundings taken in the vicinity show that there has been very little change in the lake bottom for at least 4,000 ft. out from shore, and at the location of the crib this agreed with the divers' report.

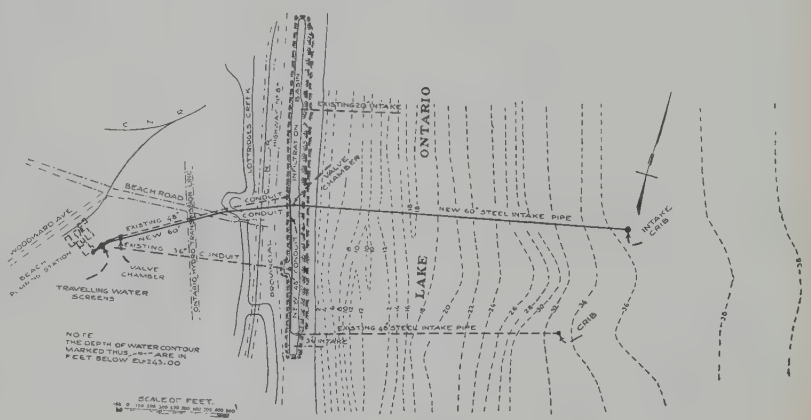

Fig. 1—General Plan Showing Location of the Various Intake Pipes

Laying the 48-In. Intake.—In 1912 the first pipe for this intake was laid in the infiltration basins, and work carried on outwards into the lake. The equipment used consisted of a scow fitted with a derrick and clam shell for excavating, and pipe lowering equipment at each end, a pile driving scow, and steam tugs. The bearing piles were first driven, and then sufficient trench was dredged out for one pipe length. Bearing piles were then cut to grade and capped, and the pipe lowered from the bottom of the scow. All trench was backfilled after the pipe had been laid. The wooden crib was built on shore, floated out to position and placed. Two expansion joints were used on the line, and wedge-shaped wooden gaskets used for changes in grade. The 48-in. riveted steel pipes were 142 ft. long, delivered on the lake shore in lengths of between 20 and 30 ft. and assembled to the required length.

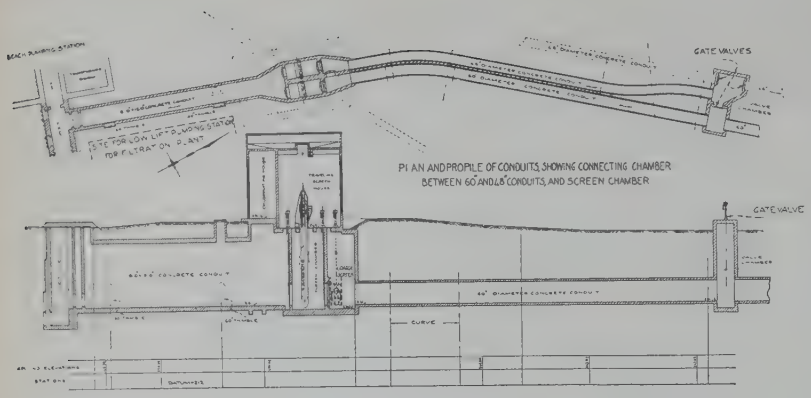
New 60-In. Intake.—The new 60-in. intake is laid beneath the bed of the lake approximately 1,100 ft. west of the 48-in. pipe, and has its intake bellmouth 3,000 ft. out from the present infiltration basins. It is concreted from the valve chamber through the bank of the infiltration basins and for about 430 ft. out from the shore line.

The steel pipe consists of 23 lengths, each about 126 ft. long, and one closing length. The material used in the pipe is open hearth tank plate steel ½-in. thick. The longitudinal seams are double riveted, with single riveting on the circumferential seams. All rivet holes were punched $\frac{7}{8}$-in. small and reamed out to full size after the plates were assembled and bolted in place. Punched holes which did not coincide to within ⅛-in or less were reamed out to $1\frac{3}{16}$-in. and 1⅛-in. rivets used. Consideration was given to pipe with electro-welded butt joints, but no tenders on this method of construction were received.

The flanges are 5 by 4 by 1 angle iron riveted to pipe and faced and drilled for 36 1-in. diameter bolts with lock washers and hexagonal nuts. The pipes were coated with a solution of coal tar pitch and linseed oil applied hot.

Five cast iron flexible joints were included in the pipe line to allow for change in grade, settlement, etc. Two expansion joints were also included to facilitate joining up the closing lengths and are shown in detail in the accompanying illustration.

The intake crib is constructed of interlocking steel sheet piling shell 22 ft. in diameter, consisting of arch web section 40.83 lb. per lineal ft. At the center of this shell, a steel cone is connected to the intake pipe by a cast iron



GATE VALVES
PLAN AND PROFILE OF CONDUITS, SHOWING CONNECTING CHAMBER BETWEEN 60" AND 48" CONDUITS, AND SCREEN CHAMBER
GATE VALVE

Fig. 2—Plan and Profile of Conduits Showing Connecting Chamber Between 66-In. and 48-In. Conduits and Screen Chambers

elbow and concreted as shown on drawings.

A reinforced concrete baffle plate, above the opening, anchored by 3-in. diameter manganese bronze bolts, prevents the warm surface water being drawn directly down into the pipe in the summer, and in winter time obviates danger from downward currents carrying slush ice into the intake.

Intake Velocities.—Velocities in the intake openings have been kept to a minimum to reduce the hazard of frazil ice formation. The six intake ports have an area of 54 sq. ft., giving a velocity of 1.45 ft. per second at time of ultimate maximum draught. As the demand is greatest in the summer months, the winter velocities should always be lower than those above stated. Other ultimate demand intake velocities are: orifice, 1.18 ft. per second; throat, 2.8 ft. per second, and in the 60-in. diameter pipe, 4.7 ft. per second.

Each of the 23 sections of the intake is supported on three pile bents, with rolling blocks bolted to the cap. Where the fill is more than 6 ft. deep, the pipe is encased in 1:3:5 concrete 12 in. thick.

The lengths of 60-in. steel pipe were fabricated at the East End plant of the Hamilton Bridge Works, loaded on cars and placed in the water at Hamilton harbor by means of locomotive cranes. From the harbor they were towed by motor boats across the bay, and beached on the lake shore adjacent to the site of the work. From this point they were handled by the laying contractor.

Construction Methods.—When construction on the 60-in. intake was commenced in June, 1927, the water supply for the city was taken through conduits from the infiltration basin, which was fed by the lake intakes previously referred to. In order that this supply should not be contaminated or interfered with in anyway, steel piling was driven on each side of the line of the pipe from the coffer dam, in which the intake valve house was being constructed, to the lake side of the basins. Dredging was then commenced in the lake for the third length of pipe, and also on land, cutting through the bank between the basin and lake.

Dredging was carried out continuously in the lake by a dipper dredge. The pile-driving scow followed up the dredge, driving the bearing piles, and behind it came the diver's scow placing caps.

The pipes were laid from the side of a barge fitted with steam winches and two outriggers, concrete counter weights being used on the opposite side for trimming. When everything was ready for pipe laying the barge was brought into line and correct position and bulkheads were removed. The pipe was then lowered on the bents and faced up. The flanges were next bolted by divers in from two to three hours and the rolling blocks secured. During the entire operation the pipes were held by the slings from the outriggers.

Where the pipe is encased in concrete, pouring was done from a scow fitted with a mixer, concrete being placed in forms through tremie pipes. Forms were built with angle iron bracing and lined with 2-in. sheeting. Steel distance plates, which rode the top of the pipe, were fixed to the top horizontal braces to ensure the proper vertical position of forms and also the proper depth of concrete.

Bearing piles were driven 15 ft. below grade of pipe, and to shale where the latter was encountered.

The outside steel sheeting for the crib was assembled as a unit on board a scow, and an opening left in the side wall sufficiently large to straddle the 60-in. intake pipe. The crib was floated to position and lowered by means of a derrick scow. The structure rests on a levelled-off shale bottom. All openings in the crib were then formed up and concreting completed. The baffle plate, anchor bolts for which were left in the crib, was then placed in position.

When pipe laying had progressed far enough from shore to permit sufficient room for working advantageously, backfilling of trench was commenced, and continued for some time after the remainder of the work was finished, being completed about the first week of December, 1927.

At the junction between the steel intake and 60-in. diameter concrete conduit in the middle of the existing in-

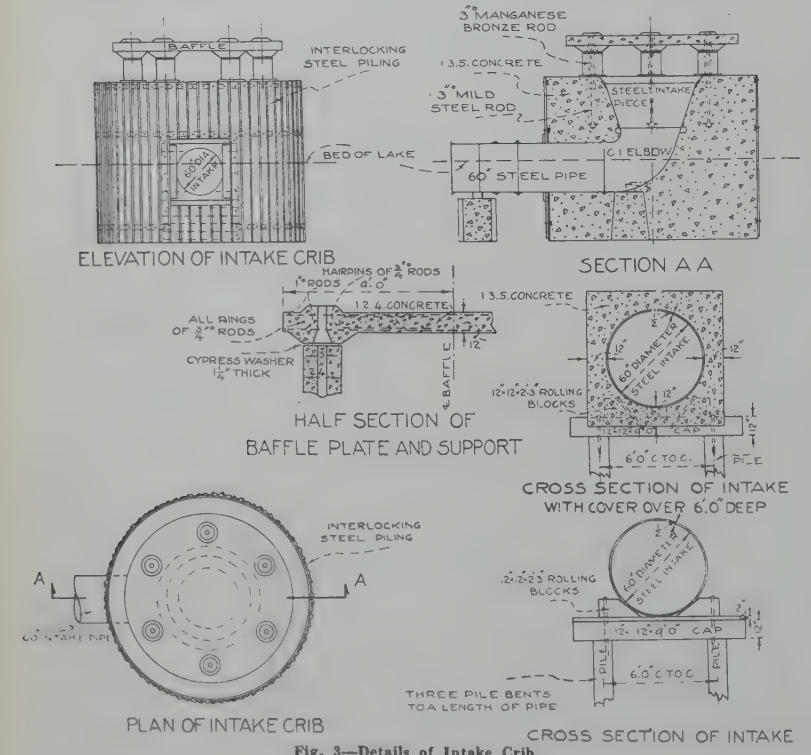


Fig. 3—Details of Intake Crib

filtration basins, a chamber was built containing a penstock on the entrance to the conduit.

60-In. Conduit and Screen House.—Work on the 60-in. conduit was commenced at the pumping station end, and proceeded with towards the infiltration basin. Excavation was done by a Bear-cat excavator, good clay being encountered until the east side of Lottridge inlet was reached. At this point the clay dropped off almost vertically and heavy water bearing gravel was encountered. Considerable difficulty was experienced in this section of the work, the trench having to be sheeted with steel sheet piling and bulkheaded.

The 60-in. diameter conduit consisted of lock joint pipe jointed in the ordinary manner with cement, and bedded in concrete to springing line.

Immediately before entering the suction well at the pump station, the water passes through traveling water screens, erected in duplicate. The existing 48-in. conduit was cross-connected with the 60-in., so that the supply from both conduits is screened.

The use of penstocks in the screen and valve chamber permits the whole supply to be dealt with by one traveling screen, while the other is out of use. The screens are 6 ft. wide with ¼-in. mesh and operate at a speed of 11 ft. per minute. Two cast iron flanged thimbles 60 in. in diameter were built into the main conduit to provide future connections to a low lift pumping station when a filtration plant is constructed.

The chlorinating house was built in conjunction with the screen house and provision made for duplicate chlorinating apparatus and weigh scales.

Laying Connection Between Old 48-In. Intake and Conduits.—The joining up of the existing 48-in. diameter intake and conduit was accomplished by use of 48-in. lock joint concrete pipe laid in the banks of the basins. Monolithic concrete was used on the curves. Pile bents, 4 ft. on centers, were used under the monolithic section crossing the east end of the basin.

This conduit was laid after the 60-in. intake and conduit were put in operation, and the infiltration basin was no longer required for the city water supply. The pipe was laid approximately 11 ft. below the elevation of the water in the basin, but it was found possible by closing the existing intakes to keep the water below invert grade by means of the pumps at the waterworks pumping station, and the pipe was laid in the dry.

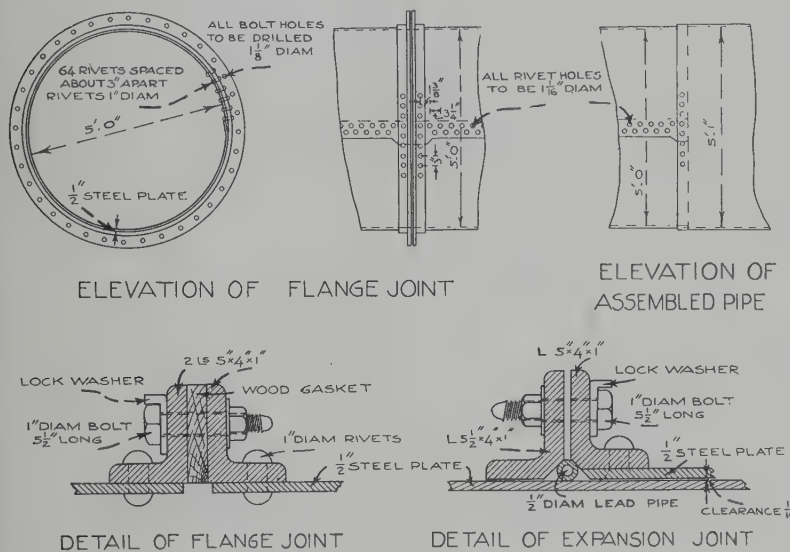

Fig. 4—Details of Flange Joint and Expansion Joint

The conduit was joined to the existing 48-in. pipe which had been laid in 1913. The first 112 ft. of the latter were of steel pipe, and when this was cut into it was found to be in an excellent state of preservation.

On the completion of the maintenance period, the entire work was inspected and was found to be in a perfectly satisfactory condition.

Acknowledgment.—The above paper was presented Feb. 15 at the annual meeting of The Engineering Institute of Canada.

Regional Planning for Kansas City.—Steps are under way for a regional plan for Kansas City. The plan involves six counties, three in Missouri and three in Kansas, and includes an area with a population of 750,000. The aims of the regional plan here are extensions of zoning regulations into the suburban area, setting aside areas for homes, parks, playgrounds, public buildings, commercial and industrial buildings, co-operation in building of highways, police protection, sanitation, construction of sewers, and maintenance of water supply.

Improvement in Utilization of Fuel by Public Utilities Continued During 1928

Preliminary figures of the U. S. Geological Survey of the total annual production of electricity by public utility power plants in the United States indicate an output of 87,851,000,000 kilowatt-hours in 1928, an increase of nearly 10 per cent over the output for 1927.

Water power was used to generate 34,747,000,000 kilowatt-hours, or about 40 per cent of the total current. Water power has generated more than one-third of the electricity produced by public utility power plants every year from 1919 to 1928. During the past four years the output by water power has increased more rapidly than the output by fuel power, and in 1928 the output would have been more than 40 per cent attained but for the abnormally dry weather in the later part of the year, which reduced the water supply of the streams used for power.

The amount of electricity generated by the use of fuels was 53,104,000,000 kilowatt-hours, or 60 per cent of the total. Of this amount, coal was used in the generation of 88 per cent, gas 7 per cent, oil 4 per cent, and wood less than 1 per cent.

Public utility companies and their power plant operators were again successful in increasing the efficiency in the utilization of fuels in the generation of electricity. The amount of electricity generated by the use of fuels in 1928 was 5.5 per cent more than in 1927. The amount of fuel consumed, however, was only 1.1 per cent more than in 1927. The increase in output was therefore five times as much as the increase in the amount of fuel consumed. The average rate of fuel consumption for the entire United States in 1927 was 1.84 lb. of coal per kilowatt-hour; in 1928 the rate was reduced to 1.76 lb., a reduction of 0.08 lb., or about 1¼ oz., per kilowatt-hour. This small saving per kilowatt-hour in generating the 53,000,000,000 kilowatt-hours of fuel-generated electricity, however, amounted to 2,120,000 tons in the year, which equivalent to about $8,000,000. In 1919 the average rate of coal consumption in generating electricity was 3.2 lb. per kilowatt-hour. The rate of 1.76 lb. for 1928 is therefore very close to half the 1919 rate. If coal had been consumed by electric public utilities at the rate of 3.2 lb. per kilowatt-hour in 1928 the increase in fuel consumption would have been about 38,000,000 tons, representing about $150,000,000.

Southeastern Water and Light Association.—The next convention of this association will be held April 15, 16 and 17, 1929, at Birmingham, Ala.

Municipal Research and the City Manager

How Research Bureaus Can Aid the City Manager

By STEPHEN B. STORY
City Manager, Rochester, N. Y.

I AM going to speak disjointedly and without plan or framework on which to hang my meagre thoughts—it violates all my research training, but it is the best I can assemble between negotiations with a bridge engineer for a bridge design, an argument over the amount a cemetery should pay upon a pavement to be used by a greater proportion of joyriders than hearses, a newspaper story on a new municipal golf course, a radio talk on Rochester products, a discussion on how to get more business for the subway, an interview with the city hall superintendent concerning cockroaches in my roll top desk, a meeting with a delegation of ladies who want a speech on recreation, a brief talk with a serious young man who wants a ginger story magazine suppressed, a dictated letter complimenting a cop on the occasion of his getting the draw and crippling a gunman armed to the teeth, a report on the progress of the indictment of a paving grafter, a delegation of barbers with an exhibit of dirty towels used by scab barbers, a few dozen telephone calls and a hell of a fine day for golf.

At the outset I must state that my remarks do not apply to the city manager who is looking at his job solely as a means of livelihood. Thank fortune this type of manager is scarce and is growing scarcer. This type of manager is little interested in improving the quality of government and is quite out of sympathy with, and beyond the aid of assistance of any agency interested in so-called better government. Having eliminated from discussion this type of individual, I want to suggest that in respect to their objectives there is no fundamental difference between the city manager and the researchers. They are both striving to make better their local government—if both succeed the livelihood proposition will take care of itself.

The research bureau men go at their jobs a bit differently from the city manager. The researchers can proceed leisurely and unhurriedly along a fairly even course, while the city manager has to move rapidly and swiftly upon some matters and slowly upon others. The bureau men work indirectly and endeavor to impress their ideas upon others while the city manager has to act directly and stand the full gaff. The research worker is detached from the actual job while the city manager has his nose stuck right into it. The researcher has time to reflect upon, and study his problem, but the city manager and his department heads know all the sensations of the chap who is juggling the cut glass pitcher, the lighted lamp, the feather and the 8-lb. dumb-bell, and who may get caressed by a hornet just overloaded with animosity.

Important Difference Between Researchers and City Managers.—There is another important difference between the workers in the research bureau field and the city manager. As one who has passed from the realm of preaching to the realm of practicing, I feel that I am in a position to recognize this fundamental difference. The researcher,—and, by the way, I am using the word "researcher" for the sake of brevity, meaning it to include all of the men who are working in research bureaus or perhaps, properly defined, those who constitute the Governmental Research Association—the researcher has no responsibility whatsoever. He is responsible for neither men, materials nor money. The directors of the bureau, of course, have a limited responsibility in this respect. On the other hand, the city manager is weighed down with a tremendous responsibility and the greater the centralization of power granted the manager under his city charter, the greater is his responsibility. As I look at it, there is nothing in the research game which accelerates a crop of gray hair beyond the ordinary ravages of time, while the city manager gets a few more every time the postman calls, the council meets, or the telephone rings. A budget preparation season ought to be good for a snow white thatch for any city manager and his department heads. I say this with all deference to the researchers and it is offered in the light of several years' experience in the research field and but a few months in the manager field.

It has always been my personal feeling that a research bureau could not function successfully as a part of the official government organization. The chief reason for this feeling is that the research bureau must have complete independence and detachment from the official organization which it is assisting or criticising. If a research bureau is dependent upon the executive or city manager for appointments of personnel, for fixation of salaries, for advancement or for bureau budgets, the very natural and human tendency is to cushion criticism and to "yes" those responsible for funds and for appointments. I feel that complete independence is absolutely essential; and it looks as though it could be obtained only by having the research bureau supported by other than public funds and by having its staff responsible to an independent board of high type trustees. Although I have suggested independent support and control, the city government and its city manager need an agency of the research bureau type. Ordinarily the city manager and his department and bureau heads have their time so completely absorbed by routine departmental and bureau duties and by contact with the public that nothing in the nature of research work can be done.

From observation and personal experience, I know that after putting in a full day the average city official has little energy and little zest to undertake anything in the nature of research, and, incidentally, most city officials have families who have some sort of lien upon their spare time.

Some of the Functions of a Bureau.—There are problems arising within the city organization almost every day which need the consideration and study that a research bureau alone can afford. I dare say that there are enough problems that will suggest themselves in Rochester within the next year, which, if turned over to the Rochester Bureau for solution, would absorb the entire time of that bureau for the next five years. Bureaus and city governments tackle those problems which appear to be capable of solution within a reasonable time, but gloss over many of the others because of their seeming impossibility of solution. I believe that all these problems could be solved if the time could be found to put upon them.

There is another function which a research bureau properly can undertake and which can be of tremendous service to the city manager. That is the function of a critic of the administration. Like all governmental administrations, the city manager form of government usually has two kinds of critics: first, those who are politically opposed to the city manager idea and possibly to the council in power and who criticise with an undoubtedly biased point of view; and second, those who favor the city manager form of government and the council group which is in the majority. These last are apt to find little to criticise in the activities of the government. Criticism from enemies is not worth much beyond serving to keep an administration on the alert, and, equally so, criticism from ardent admirers is not worth much because of it "yes, yes" character. How-

ever, no thinking city manager can afford to blind himself to the desirability of having a critic whose criticism is fair, just and constructive and whose objective is, or should be, essentially the same as that of the city manager; namely, in seeing to it that the government delivers to the people of the city the highest type of service to be obtained. A bureau should have no ax to grind, and its disagreements with the administration should be perfectly friendly. Above all, it should be patient. The bureau which rushes into print with its criticisms of the manager for the sake of bureau advertising should receive but little consideration from the manager. If the manager's objectives, because of political expediency or a defective charter, are not coincident with those of the bureau, and the two are not working toward the same end, they had best not be friendly and not work together.

Appraisal of Results.—At all times the city manager and the taxpayers should be eager for an appraisal of results or of accomplishments. The city manager usually is not in a position to appraise these results and, even if he should be, his appraisal, if flattering, is liable to be condemned by his enemies, and if unfavorable, is magnified as an admission of weakness. Under any circumstances, self-appraisal is not acceptable as being biased and not in good taste. The appraisal of results can best be made by a bureau possesed of all its independence and detachment.

There is another way in which a bureau can be of great value to the manager. There are many times when the manager has to do something which, though right, just and proper, is unpopular and imperfectly understood. It takes a bit of courage under less circumstances. Maybe the council is not on the right track and the manager has to disagree with it—the pepole to whom he has to look for his job—he has to drive hard to get them to do the right thing. Then is the time when he needs encouragement, the little word of approbation which helps him to stick it out and finally get results. The bureau can do this. It does not have to shout, far from it—all he needs to know is that some clear thinking group agrees with him. It does not take much to help one over a rough and stony road.

The research bureau can further aid a city manager by acting as one of his ears. I think that, if the proper tactics are used, a research bureau can find out through different channels and can report to the city manager the feeling of the man in the street and of Mr. and Mrs. J. Taxpayer concerning the government or some of the things it is doing. Curiously enough, I have found that the surface indications which we get at the City Hall register two extremes. The report that everything is rotten comes from the knockers and kickers who drop in to vent their spite. On the other hand, the administration is the most wonderful ever in the words of those who are seeking jobs, favors or concessions. Our great need is for information which is clear and undistorted about the public's attitude on questions. Why is not reading the public pulse one of the proper activities of a bureau in its service to the city manager?

Cooperative Work.—The research bureau should be a staff agency to the city manager and as such its work must be highly cooperative. I want to make the observation that once a bureau decides to act as a staff agency for the city manager, or for any city administration, it must continue to act in that capacity without regard to the personality of the manager. Once it has put its hand to the wheel it must keep it there. It cannot be cooperative with one city manager and militant with his successor. If it gets into close relationship with the manager it almost automatically becomes a part of the administration. It must sink or swim with it.

As much tact is required on the part of the bureau workers under the close relationship which I have indicated as under a situation where the bureau has to be militant in order to get results. It must guard its relationship carefully and bear in mind that it is contacting with hard worked men who are striving to produce results, and who, because they are giving 100 per cent of their ability and time to the job, are sensitive and touchy to bureau suggestions. The bureau must be careful never to substitute itself for those who are carrying the real responsibility. The city manager, with whom the bureau is acting as a staff agency, has a responsibility to see that the proper balance is maintained between the bureau and his men.

A bureau must be patient. Just because they are working in close cooperation the researchers can easily become impatient for results. It is often not expedient to do a certain thing at a certain time, or perhaps the manager or his department head may not have had time to study the problem.

Personally, in Rochester, I have felt that my job as city manager was simply an extension of bureau work—I have only moved nearer the firing line. When Baker and Higgins left the Rochester Bureau to enter the city's service we never felt that they had left us—they were going to carry on as bureau men working for better government. I humbly hope that I can maintain my ideals of government and can carry them out in practice.

Probably I am biased in my ideas about close relationship. If I am, just lop off a fair discount from what I have said.

Acknowledgment.—The above is taken from a paper presented at the 17th annual meeting of the Governmental Research Association.

Group Insurance for City Employees

The Plan Adopted by the City of Kenosha, Wis.

By P. J. HURTGEN
Director of Public Works, Kenosha, Wis.

NO part of a city's business should receive more thought today than the problem of maintaining the good will and cooperation of the employees. The value of public good will has long been recognized and very frequently capitalized. No plan has done more toward maintaining that personal touch in our city management and securing the loyalty of the employees and the employees' families than has our plan of Employees' Insurance.

The Plan.—Our plan of insurance provides protection for the family of a deceased employee during the period of readjustment following the death of the wage earner. It does away with passing the hat at the death of an employee and puts on a business basis what was formerly taken care of through charity. It provides employees with insurance protection that many could not get otherwise.

Unless your employees are better protected than the average, and I am certain they are not, you will find about 10 per cent that are adequately insured, 30 per cent with inadequate protection and 60 per cent with little or no protection. The U. S. Chamber of Commerce estimates that 20 per cent of the working men cannot get insurance because of physical impairments.

Employees' insurance is issued without a medical examination, except in a few states whose statutes require a brief medical inspection. Insuring your employees relieves them of some of their worries and creates in them a spirit of cooperation.

The Cost.—The cost of employees' insurance is small: about 3 ct. a day per employee, gives each of your employees $1,000 insurance. The exact cost is determined by the average premium based on the age of the employees. The rate of 3 ct. per day applies to those employees under 56 years of age. After the age of 56 years is attained, the coverage drops to $500 with the premium remaining the same.

Under the plan effective in Kenosha, heads of departments are entitled to carry 2½ times as much insurance as other employees. In order to procure insurance for your employees, you must interest 75 per cent of the employees to become subscribers to the insurance.

Amount of Average.—There are several plans of insurance offered by the various insurance companies. The amount of the coverage for your employees should not exceed an amount that can conveniently be financed by the low salaried employees. When the insurance plan was discussed by the

employees of our city, it was voted and agreed that all employees who had not attained the age of 56 years would take coverage in the amount of $1,000 and those who had attained the age of 56 years $500, with the understanding that heads of departments could later apply for and receive 2½ times the above amounts, and after the plan went into effect, the department heads who wished the additional insurance applied for and received the additional amount. Under our plan the amount of insurance for which each employee is to be insured is determined by class as follows:

Class 1. Employees who have not attained their 56th birthday, other than department heads $1,000
Class 2. Employees who have attained their 56th birthday, other than department heads 500
Class 3. Department heads who have not attained their 56th birthday..... 2,500
Class 4. Department heads who have attained their 56th birthday..... 1,000

However, if the employees in Class 1 had felt able to meet the premium on a $1,600 policy, they would have been free to select a policy up to that amount, and then in that case, the department heads would have been eligible to insurance up to $3,000.

However, the amount of the insurance must be based on some plan which precludes any individual determining what amount of insurance there will be on his life. This must be determined by the group of which he is a part.

Maximum Insurance Obtainable.—The maximum insurance obtainable for department heads is $10,000, and employees not department heads, $4,000. To obtain these maximum amounts the total coverage on all employees must be not less than $1,500,000 and this amount of coverage could easily be obtained in the large cities where many employees are carried on the pay roll.

Employees who have reached the age of 80 years are not eligible for insurance.

Inasmuch as a man's rating per $1,000 insurance at:

25 years of age is	$ 0.54	monthly
35 years of age is	.58	monthly
45 years of age is	.86	monthly
55 years of age is	1.71	monthly
60 years of age is	2.52	monthly
65 years of age is	3.76	monthly
70 years of age is	5.61	monthly
80 years of age is	12.20	monthly

and if you include firemen and policemen in your group, there is an extra rating of 25 ct. per month on each.

As the employees' rating, as a group, will be based on the above average rating, it becomes apparent that the lower the average age of the group, the lower the monthly premium will be, and to bring this rate down to a fair average, especially where there are many old men, it is recommended to give the oldest men half the amount of insurance at age 56, for the need of insurance for an old man is not in proportion to that of the young man, who has responsibilities, such as establishing a home, small children, etc., whereas an old man's responsibilities are mostly confined to taking care of his wife.

When the Employee Leaves.—In case the employee leaves the employ of the city during the continuance of his insurance coverage, the employee may, if he applies for insurance within 31 days of termination of his employment, be entitled to have issued to him without medical examination and upon payment of the premium for his then attained age, a contract of life insurance in any one of the forms customarily issued by the company, except term insurance.

Permanent and Total Disability Benefit.—If an employee while insured and before reaching his 60th birthday becomes wholly disabled by bodily injuries or disease, and will be permanently, continuously and wholly prevented thereby for life from engaging in any occupation or employment for wage or profit, no further premium will be collected and the amount of his insurance will be paid to him in a fixed number of installments chosen from the following table:

Number in Years During Which Installments Will Be Paid	Amount of Each Installment Payment for Each $1,000 Insurance	
	Annual	Monthly
1		$85.00
2	$509.00	43.27
3	345.00	29.33
4	263.00	22.36
5	214.00	18.19
10	116.00	9.86
15	84.00	7.14
20	68.00	5.78

Under the Kenosha plan, a man must have been in the continuous employment of the city for a period of six months to be eligible for insurance and must apply for insurance within 90 days after date of eligibility.

How Group Insurance Is Handled at Kenosha.—This whole plan of Employees' Insurance is in reality what insurance companies term "Group Insurance." Group insurance can only be written in cases where the employer pays at least two-thirds of the premium. Under existing state laws, few, if any, cities are authorized to expend taxpayers' money for such purposes, this being true in Wisconsin and wishing to give our employees the benefit of wholesale insurance, we organized the Mutual Benefit and Insurance Association of the Employees of the City of Kenosha. Two-thirds of the premium is paid by the employees into the association, the association in turn issues to the city a check by the association's treasurer equal to the two-thirds which the employee is required to pay, and the city then forwards to the insurance company the amount deducted from employees and in addition, a check for the exact amount received from the association. The entire transaction is handled by the city and thus the employee is put to no trouble whatever in taking care of the premiums.

The city council by resolution authorized the city treasurer to receive and disburse these funds as above outlined. In presenting this subject, I have outlined the plan adopted by the city of Kenosha. There are several other plans offered by insurance companies that may fit in better with local conditions in the many cities represented here. Your local insurance representatives can best work out with you the plan that will give you and your employees the best protection for the money expended. You, at least, owe it to your faithful employees to offer them some plan of protection and give them an opportunity to make full use of it if they so desire.

Acknowledgment.—The foregoing is taken from a paper presented before the Wisconsin Section of the American Water Works Association.

Municipal Forest Planted in 1896 Paying for Itself

As far back as 1896 the city of Little Falls, N. Y., was purchasing lands with the view of ultimately controlling the watershed of the neighboring Spruce and Beaver Creeks. Today the water supply of this city of 14,000 population is protected by municipal ownership of 4,003 acres of land at the headwaters of the two creeks, writes R. R. Fenska of the New York State College of Forestry.

Up to 1927, 1,200 acres of mature timber was in a very nearly virgin forest of spruce, balsam fir, hemlock, yellow birch, maple, and beech. In 1926, under the direction of a forester, 5,000,000 board feet of timber, including both softwoods and hardwoods, was marked for cutting. This timber was so selected that its removal will not in any way impair the value of the area as a protection forest. Logging began in the fall of 1927 and will continue until the spring of 1929. The timber has been sold to a concern specializing in high grade lumber for piano sounding boards. The revenue from the sale will reimburse the city for the purchase of the land and timber.

The contract under which this timber is being cut is similar to the contracts under which the Forest Service of the United States Department of Agriculture sells national-forest stumpage. Young reproduction already on the ground, together with the seed in the duff, will insure rapid regeneration on the areas left open by the cutting of merchantable trees. To increase the percentage of spruce in the new stand all skidding and hauling roads will be planted in the spring of 1929 with spruce transplants. The 1,100 acres of immature timber will be ready for a selection cutting in about 28 or 30 years.

During 1928 a quarter of a million trees were planted on open portions of the Little Falls forest. Since 1916 there has been established on the forest a total of 845 acres of forest plantation, at an average cost of $10 per acre. The plantings made during 1927 cost only $8 per acre. The present program calls for the planting of from 150,000 to 250,000 trees each spring until the remaining 858 acres of abandoned farm land are reforested.

The Need of Political Engineers

In a recent editorial article we said: "If engineering is the application of science to problems of economic service, then engineers should not hesitate to extend their activities into the uttermost parts of the social realm. Certainly there is as much need of scientific study of the economic effects of laws and ordinances as of the scientific study of strains and stresses. Who, we ask, is better equipped for such study of political economics than is the engineer?"

We were speaking of laws that relate to taxation for street improvements, all of which, in our opinion, are archaic and act to obstruct progress in city highways. Bottle-neck streets and bumpy pavements disgrace nearly every city, yet we go somewhat complacently, even though swearingly, along, making no effort to change the laws that place the entire burden of cost of all street improvement upon the owners of abutting property. That burden surely should be distributed, and the failure to distribute it accounts mainly for the prevalence of poor pavements and congested city thoroughfares.

City engineers encounter many another law or public practice that is detrimental to progress. For example, the net income of water departments usually becomes part of the general fund, and is often used for purposes entirely foreign to furnishing an adequate supply of pure water. There is no defense for such practice, except that "it has always been the practice." As a result of it, and because of certain laws, the taxpayers are often called upon to vote upon major improvements in, or extensions of, the waterworks. It needs no argument to prove that voters can not decide such matters intelligently. As well ask voters to diagnose the cause of a disease, or to prescribe its remedy.

Living in a democracy has served to blind most of us to the foolish practice of asking voters to solve economic problems relating to public affairs. If it be answered that the voters are not usually asked to solve such problems, but are merely asked to decide whether a given public improvement should be undertaken, our reply is: One of the most important, and often the most difficult, of economic problems is the determination of whether a proposed improvement should be undertaken at all. In his "Economic Theory of Railway Location" Wellington repeatedly emphasizes the economic importance of determining first of all whether a proposed railway will be profitable. His preface contains his justly celebrated definition of engineering, and his ridicule of the type of "engineers" that put multitudes of men to work needlessly.

Civil engineers have usually been content to let the voters or the directors of companies tell them what and where to build structures, without often attempting to express an opinion as to the economic wisdom of the project. Our contention is that this attitude toward a major economic problem is unwise, and that the public should be taught to seek the advice of engineers and to act upon that advice, not merely as to the design of a structure but as to the wisdom of building it. It will involve years of effort to bring about such a change in general practice, for there are not only public inertia and ignorance to be overcome, but many laws to be wiped off the statute books.

President Coolidge's Unwise Admonition Against Municipal "Extravagance"

Again President Coolidge inveighs against municipal extravagance, but again he fails to prove his case. It is not sufficient to contrast the decrease in federal debt and annual expense with that of cities. Nearly all the federal debt and much of the increased federal expense are the consequences of the world war. Moreover, the rise in prices and wages that were consequent upon the inflation of currency during the war, account for most of the increase in the cost of municipal government, the balance of the increase being usually accounted for by the rise in productivity of our people.

President Coolidge has been singularly efficient as a reducer of federal expenses, but he has not shown, in any of his public utterances at least, appreciation of the two economic factors just mentioned—(1) rise in prices and wages and (2) increase in per capita productivity.

This increase in productivity is what has made it possible for nearly every American family to own at least one automobile. If, then, these same people find it not only desirable but possible to own better pavements over which to drive their machines, it will be futile to read them lectures on "economy" as to that sort of purchasing—futile and positively misdirected exhortation.

A very great part of the increase in municipal expenditure has been for educational purposes. Shall this be curtailed?

Another considerable part has been for sanitation. Shall this be curtailed? Shall we spend less for sewers and sewage disposal? Shall we spend less for adequate water supply and proper "treatment" of the raw water?

Those of us who are best qualified to know, would tell President Coolidge that neither our sewers nor our

waterworks are overbuilt or overmanned. Quite the contrary. Here is Chicago, for example, that has just been ordered by the federal court to build sewage disposal plants. There is many a community that would benefit from such an order, for most of our rivers are badly and unnecessarily polluted.

When the average American is about to leave for Europe or Asia, he receives typhoid vaccination. Why? Because most of the cities of Europe and all those of Asia are without pure water. It costs money to provide adequate sanitation, but most Americans are willing to pay the bill for devices and chemicals that prevent typhoid and similar diseases.

President Coolidge looks only at the millions spent by our cities, without analyzing the nature of the expenditures, to say nothing of weighing against those expenditures the value of the services and things secured.

There are certain "economies" that are the worst of extravagances, for they result in the wastage of health and life, and the halting of industrial progress. Against the cost of progress there should always be set the profit of progress. Russian and Chinese cities are exceedingly "economic," if you measure their annual expenses in per capita outlay. Yet they illustrate the acme of municipal waste, for their saving in money is at the expense of enormous death rates and a general ignorance that is appalling.

Is Scientific Education Sufficiently Scientific?

Effective methods of solving problems and well established habits of using those methods, constitute all there is of good education.

An effective method is the mental tool, and established habit is the skill in its use resulting from practice. Few educators, we believe, will question these principles, which makes it the more surprising that so many educators fail to apply them. Tested by these principles more than half the time of students below the college grade is wasted; and a very large part of student time in college is almost thrown away.

For example, college text books on political economics fail utterly to teach methods of solving economic problems. Most of them do not even attempt to teach such methods, but merely present the results of the thinking of other men. The same applies to history, except that in the latter case usually not even the results of thinking are presented, but only series of events, supplemented perhaps by the historian's opinions about some of them. Biology, whether in the animal or in the vegetable kingdom, is still in almost as useless a stage as an instrument of education as is history. The languages are obviously not taught as tools of thinking. Even logic, which comes with the greatest of claims as a teacher of correct methods of solving problems, departs without having fulfilled a tithe of its promises.

Geology is curiously like history, even yet, little but a collection of facts, insofar as it relates to paleontology, and scarcely more with respect to the rest that it teaches. What boots it that I can tell granite from mica-schist, if I still remain incompetent to solve an original problem in petrology? What have I truly learned as to methods of attacking such problems, if all I have learned is how to distinguish one mineral or one rock from another? I am no better qualified as a thinker than is the botanist who can merely name the genus and species of a flower.

Naming and classifying are desirable parts of scientific knowledge, but after all they are merely the language of a science, and not its methods of research or of problem solving. The text books in many branches of science remain little else than scientific dictionaries.

When we pass into the realms of physics and chemistry a change appears. Here theories are in ascendence. The causes of effects are shown, and mathematical relations are often expressed in formulas. But even here something is usually lacking. Rarely are we told just how Faraday came to discover the relationship between electricity and magnetism, for example. We are merely told what the relationship is. This, however, leaves us helpless to establish similar relationships ourselves, or even to solve vastly simpler physical problems unaided.

We learn that atoms unite in definite proportions as to weight, but how many of us know even the name of the discoverer of "the atomic theory"? And if we chance to remember his name, how many of us know how Dalton came to make his epochal discovery? And if we know that, how many of us can tell just what principle of reasoning Dalton applied in that research problem? Or why he felt justified in announcing the law without waiting to test it by more than a very few facts?

Perhaps one reason why we are so seldom taught the methods used by successful researchers is because research is commonly regarded as the special empire of genius, through which the average man may wander with awe but not with personal profit. If so, just here is where our educational system is perhaps most weak. It fails to recognize that the methods used so effectively by research geniuses are the identical methods that every man must use in the successful solution of any problem.

The preliminary gathering of many data; the careful classification and analysis of the data; the memorizing of a great many facts; the forming of an hypothesis or theory that explains certain facts by showing their cause-effect relation; the testing of the hypothesis by appeal to facts not used in forming the hypothesis; the constant use of simple analogies or likenesses in framing hypotheses—these are some of the principles that successful business men, as well as successful researchers in physics, employ. But how often are these principles taught in text books? And even when partly taught, how often is the student given such prolonged coaching that he habitually applies the methods in after life?

Judging from the meager use of technical libraries by engineers, there is a woeful lack of application of the first principle above given, namely "the preliminary gathering of many data."

Construction Features of Granville Dam for City of Westfield, Mass.

How a $630,000 Earth Dam Project Is Being Handled

By E. B. MYOTT

Resident Engineer, Fay, Spofford & Thorndike, Consulting Engineers, Boston, Mass.

THE construction of this project, now under way, involves a total expenditure, exclusive of the purchase of land, of $630,000. The work comprises the building of an earth dam and appurtenant structures, the preparation of the reservoir site for the storage of water, and the building of a short supply main. Most of the work is being done under contract.

Bids for the work were received Sept. 12, and the contract was awarded to the low bidder Oct. 28, 1927. Fifteen contractors submitted bids, ranging from $430,000 to $880,000; the lowest bid was 26 per cent below the average of all bids.

Construction work began in the late fall of 1927 and continued to February, 1928. Only a very small amount of work was done during this period; namely, the construction of a contractors' camp, the laying of about 600 lin. ft. of 20-in. pipe, and the erection of a cableway. Work began in earnest in April, 1928, and was carried on as fast as practicable until the first of December, 1928, when all operations were stopped on account of weather. During this period, work costing $350,000 was completed. The indications are that the project will be completed well within the specified time of Oct. 31, 1929.

Order of Operations.—The order of operations decided upon at the beginning of the work required the completion of all concrete work and a small amount of the embankment during 1928. Although it was necessary to do much more rock excavation and concrete work than was originally planned, due to the character of the foundation material, all of the concrete work was practically completed and also about one-quarter of the embankment.

Work was first started, at the dam, on the outlet conduit. The construction of the cut-off wall, the preparation of the dam site for the embankment and the construction of the upper gate house then followed and this work was carried on simultaneously. During the latter part of the season, the excavation of the road on the south bank of the dam, the construction of the spillway and spillway channel and the lower gate house was nearly completed; the borrow pit was opened and the earth embankment completed to an average height of 16 ft.; a considerable amount of

The Stone Toe

work was done in preparing the reservoir site for the storage of water; and the 20-in. supply main was completed.

Outlet Conduit.—The outlet conduit consists of a reinforced concrete pipe 42 in. in diameter, and a 24-in. cast iron pipe embedded in concrete, about 740 ft. long, built in a rock trench varying in depth from 3 ft. (outside the dam) to 25 ft., and averaging about 15 ft. The flow of the brooks is diverted into the conduit through a special inlet structure. It is discharged into the old brook channel a considerable distance below the dam. The conduit passes through the upper gate house, where gates will control the flow of water in it.

The construction required especial attention, as it was necessary to establish the profile as the trench excavation progressed. The rock encountered for the entire length of the conduit was granitish gneiss, traversed by many seams in a very irregular manner, and in many places badly disintegrated. This not only made the excavation much more costly to the contractor, as a large amount of rock was excavated without blasting, but it was necessary to remove much more rock and use much more concrete than originally anticipated. Only light charges for blasting were permitted by the specifications, and this specification was strictly enforced. The depth of all holes only average 2.6 ft. and the amount of dynamite used was kept to a minimum.

The conduit was built in sections averaging 40 ft. in length. Concrete was first poured to the spring lines of the 42-in. The second pour was to a height of 9 in. above the crown. The cast iron pipe was then laid and the concrete poured around it.

Wooden forms were used for the 42-in. conduit. They were built semi-circular, in sections 10 ft. long, of 2-in. by 8-in. ribs spaced 2 ft. on centers, lagged with ⅞-in. by 1⅞-in. stock.

Concrete collars were built about every 30 ft. at the bottom and sides of the trench and to the top of the banks of the trench, to prevent any seepage along the conduit.

A 400-ft. cableway was used for removing the excavated material, handling the cast iron pipe and other material over that part of the trench where the excavation was the deepest. A Byers crane was used for this purpose on the remainder of the trench. Most of the concrete was poured from portable mixers located along the bank.

This structure was completed in four months at an average cost of $67 per linear foot.

Cut-Off Wall.—It was thought, previous to construction, that only a simple cut-off wall would be required. The contract drawings called for a concrete wall to be built across the floor of the valley in as narrow a trench as possible, resting on bed rock and extending above the surface of the ground about 5 ft. As bed rock is very deep on the banks of the valley, it was planned to use timber sheet piling together with a simple wall there, or an earth cut-off. Timber piling could not be driven and it was decided to build the cut-off of concrete for the entire length of the dam.

Excavation for cut-off wall was first started on the south side of the floor of the valley. As soon as bed rock was encountered, it was tested for watertightness. One-inch holes 10 ft. deep took water at the rate of about 5 gal. per minute under a 20-ft. head at the bottom of the hole. This fact, together with knowledge obtained regarding the character of the rock from the outlet conduit excavation, caused a change in the design of the wall.

The material overlying bed rock, across the floor of the valley, is silt, sand, gravel and large boulders and is very compact; on the north bank there is a layer of hardpan overlying soft, reddish, fairly uniform sand; on the south bank, the material is silt, grey granitish sand and fine gravel; and at the southerly end of the dam, there is a considerable amount of rock flour silt.

The trench across the floor of the valley was opened to an average width of 8 ft. at the bottom and 20 ft. at the top, but on the banks of the valley, the trench was kept to a minimum width of about 3 ft. A seal coat of concrete was poured over the bed rock and the bed rock was grouted. The wall across the floor of the valley was built on the downstream side of the trench. It was built in sections 40 ft. long and that

Cut-Off Wall on South Bank of Valley

part below ground surface was built in steps. Walls were built across the trench at the end of each section, enabling the puddle backfill, which consisted of rock flour silt and topsoil, to be placed in sections. The wall across the valley was built to an average height of 10 ft. above the ground. Particular care was taken in grouting the foundation and building the wall at its intersection with the outlet conduit. On the banks of the valley, the depth of the trench varied from 12 ft. at the foot of the bank to 9 ft. at the top and the height of the wall above the ground surface varied from 10 ft. at the foot of the bank to 5 ft. at the top. Passageways were left in the wall for use later in hauling the material to the dam for the embankment.

Grouting Bed Rock.—The entire length of bed rock was grouted. A set of 1-in. drill steel was used which gave a diameter of hole at the top of about 3 in. The holes were spaced 15 ft. center to center in two lines about 7½ ft. apart and the locations of the holes were staggered. A total of 60 holes were drilled, 52 of which accepted grout. At the beginning of the operation, the grout was mixed in the proportion of 1 part cement and 7 parts water. As the hole tightened, the mix was increased to 1 part cement and 3 parts water. The grout was first applied under a pressure of 15 lb. and gradually increased to 80 lb. The minimum amount of cement used per hole was ½ bag, the maximum 75 bags and the average 10¼ bags. A very small amount of grout was lost. The total cost of grouting was $2,475 or about $4.25 per linear foot of hole.

At the present time, the cut-off wall is practically completed. Four months were required to build the wall and the average cost per linear foot was $92.

Upper Gate House.—The upper gate house is a reinforced concrete structure 22 ft. by 30 ft. and approximately 85 ft. high with a 1-story brick superstructure. It consists of a drywell and a wetwell. The wetwell does not extend to the very bottom of the structure, there being a large section of mass concrete about 28 ft. high underneath it. The reinforced walls for a height of 28 ft. above the foundation are 4 ft. thick; and above this they are 3 ft. thick.

Lower End of Spillway Channel

This structure was built on a rock foundation of the same character of rock as was encountered in the outlet conduit trench. It was necessary to excavate more rock and to place more concrete than was originally estimated. The concrete in this building was placed in pours as large as practical, averaging about 100 cu. yd. per pour. The concrete for the lower part of the structure was poured by gravity from a mixer located on the south bank; that in the middle part of the structure was handled from the mixer by a crane. A steam hoist elevator was used to handle the concrete above this elevation. The forms consisted of 2-in. by 6-in. spruce planed on one side with 3-in. by 4-in. studs 2 ft. 0 in. center to center and 4-in. by 6-in. ribbons 3 ft. 0 in. center to center. The forms were double wired 3 ft. 0 in. center to center both ways.

The progress of the work depended upon the construction of the forms and as only a limited number of men were able to work on the forms at one time, the construction of the building progressed slowly.

The total cost of this structure will average about 95 ct. per cubic feet of gross volume.

Rolling Earth Embankment

Main Dam.—The dam is an earth embankment built by the layer fill method, with a stone toe and heel, and stone facing on the upstream slope. 240,000 cu. yd. of earth, 30,000 cu. yd. of stone, 8,000 cu. yd. of gravel and 2,000 cu. yd. of soil dressing will be used. The stone embankments and facing have been laid out to utilize all of the stone excavated for appurtenant structures and all stone encountered in the borrow pit. The average cost per cubic yard of the entire embankment will be about 85 ct.

Preparation of the Site.—The first work in the construction of the main dam was the preparation of the site for the embankment. This work included the removal from the site of all stumps, topsoil, loose boulders, and material which in its natural state was quite permeable.

A large part of this work was done by a steam shovel. The final operation

of cleaning up the loose material left by the shovel was done by hand labor. This work progressed slowly at first due to the difficulty of hauling the material away. The Linn tractor was of particular value, having no difficulty in hauling a full load over rough ground on a grade of 20 per cent.

Many boulders were encountered in the stripping of the site. It was necessary on account of these boulders to do a large amount of the work by hand labor. All loose boulders were removed for use in building the stone toe of the dam.

Work at the Borrow Pit.—While the work in preparing the dam site was under way, a road was excavated to the borrow pit and a part of the pit was grubbed and stripped.

The pit is located on the north bank of the valley about ¼ mile from the center of the dam. It is on a side hill with an average cross slope of about 3 to 1.

Investigations conducted previous to construction and since proved to be correct, showed that this side hill was covered by a layer of hardpan approximately 10 to 15 ft. thick at its junction with the floor of the valley and 60 to 80 ft. deep at the top of the hill. Underlying the hardpan, there is a large volume of uniform reddish, micaceous sand which is very permeable, and therefore unsuitable for the earth embankment.

The contract permitted the contractor to open the borrow pit in any location he deemed desirable on the side hill, but not nearer than about 300 ft. from the embankment. He elected to open the pit at about elevation 550, about 10 ft. above the top of the dam, where the depth of the overlying hardpan would be great enough to permit the economical excavation and handling of the material. The road from the pit to the floor of the valley at the dam site is on an average grade of 10 per cent. As the height of the embankment increases, the alignment of the road will be changed somewhat, thus decreasing the grade of the road.

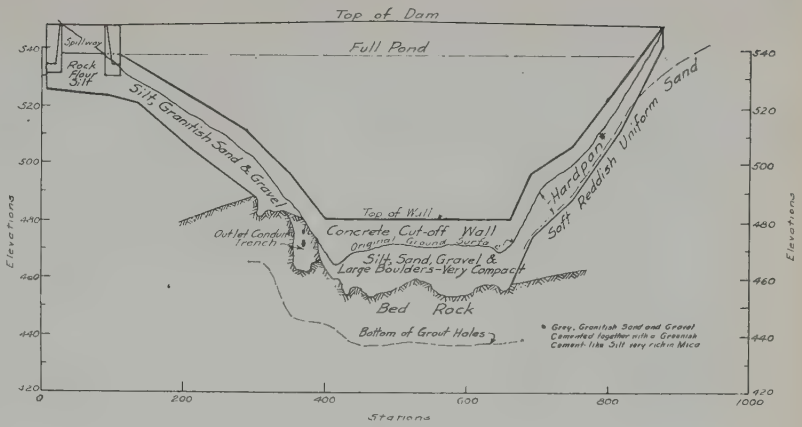
The excavation in the pit is being carried to the entire depth of the good material. It is being made by two Byers steam shovels, equipped with ¾-yd. buckets. These shovels are capable of excavating the bank to a height of about 25 ft. It was first planned to terrace the cuts with depths not greater than could be made by the shovels in one cut, but this idea has been abandoned due to the difficulty of handling the hauling equipment in the pit. When the height of the bank reaches about 25 ft., a cast over cut is made from the

Cut-Off Wall at Intersection with Outlet Conduit

top of the bank by a Byers gasoline shovel equipped with a 1-yd. bucket. This shovel casts the material over the bank, where it is rehandled by the steam shovels before another cut into the bank is made. It is not necessary to use the gasoline shovel on this work all of the time.

The hardpan is very difficult to excavate. The teeth of the buckets are made of manganese steel, but it is necessary to change them frequently. The excavation of this hardpan could be done more economically by larger and more powerful shovels, but, however, the size of the shovels being used fits in very well with the general scheme of handling the material. They are quite speedy and are capable of excavating the material as fast as it can be properly handled at the embankment. If larger shovels were used, additional spreading, rolling and hauling equipment would be required.

Hauling of Material from the Borrow Pit to the Embankment.—At the beginning of the work, the contractor was undecided on the type of equipment to use for hauling the material from the pit to the dam. Numerous types were considered; namely, belt conveyors and trucks, auto trucks, Linn tractors, and tractor trains. The contractor purchased a 7-ton Linn tractor for general use on the job, and as soon as the earth embankment was started, this machine started hauling from the pit.



Profile of Cut-Off Wall

A 60-hp. Caterpillar tractor, manufactured by the Caterpillar Tractor Co., and two bottom dump steel wagons, manufactured by the LaPlant-Choate Manufacturing Co., were purchased on trial. Three-ton Mack trucks equipped with dual-pneumatic tires on the rear wheels were hired. Time studies were made to determine the comparative cost of hauling the material by the machines. These studies were made at the beginning of the work when hauling conditions at the embankment were poor and at a time when the pit was not large enough to permit the easy handling of the equipment there. As a result of this study, additional tractors and wagons were ordered at once. As the hauling conditions at the embankment and in the borrow pit improved, it was found that the Caterpillar tractors could haul three wagons and the Linn tractor could haul in addition to its usual load, one wagon, and therefore, additional wagons were ordered. At the end of the season, the material was being hauled by three tractor trains of three wagons and by the Linn tractor and one wagon. It is expected that the remainder of the filling material will be hauled by this equipment only.

Work on the Embankment. — The work at the embankment consists of

Work at Borrow Pit

spreading and rolling of the material; the sorting from the earth of roots over ½ in. in diameter and stones over 6 in. in the greatest dimension. A 60 hp. Caterpillar tractor equipped with a LaPlant-Choate bulldozer is used for spreading the material. A 7-ton Buffalo-Springfield roller is used to assist the other equipment in compacting. A 1½-ton truck, a foreman and five men are used to sort the roots and stones, direct the dumping of the earth and the placing of the stone and gravel.

Amount of Compacting.—Perhaps the most essential factor to consider in building earth embankments is the compactness of the mass, as the greater the compactness the greater the weight, and in most cases the greater the imperviousness.

The specifications for this job require "the filling material shall be distributed in approximately horizontal layers not exceeding 6 in. in thickness when compacted. . . . The compacting shall be done by approved rollers having grooved or banded rolls and operated by mechanical power except that in small embankments and around the structures other means approved by the engineer may be used. The heaviest wheels of the roller shall cause an average pressure of at least 250 lb. per linear inch width of roll. The roller shall pass over every portion of each layer as many times as may be necessary, but not less than six times in any case."

This specification conforms closely with the specification commonly used for the building of layer filled embankments. The specification commonly used does not include an allowance for compacting done by equipment other than that used for rolling alone. Before motorized equipment became so common in use, the compacting of embankments was done by horse drawn rollers and by the trampling of stock. In the early dams, the material was hauled to the embankment in most cases by horses and wagons, and later by industrial trains. At the present time, with the heavy motorized equipment available, such as we are using in Westfield, consideration must be given to the amount of compacting which it does. It is true that this type of compacting is not entirely uniform, but it can be quite carefully controlled.

The engineers on this project were very much pleased when the contractor decided to use tractors and the large wagons. Surely the compacting resulting from a 10-ton tractor working on the embankment is very beneficial.

The distance travelled and the area covered on the embankment during a 9-hour day, while building a layer 5½ in. thick after being compacted, together with the wheel loads of all equipment have been determined. With these data and knowing the area of the embankment, the average number of trips made on the embankment per layer is computed for each machine. The product of the average number of trips and the average wheel load per linear inch width of tread gives the relative amount of compacting.

The relative amount of compacting given for the tractor treads should possibly be reduced to conform more closely with the amount of compacting given for wheel loads, due to the additional concentration of a wheel load. However, considering wheel loads only, the amount of compacting done by the wagons alone exceeds the minimum requirement of the specifications.

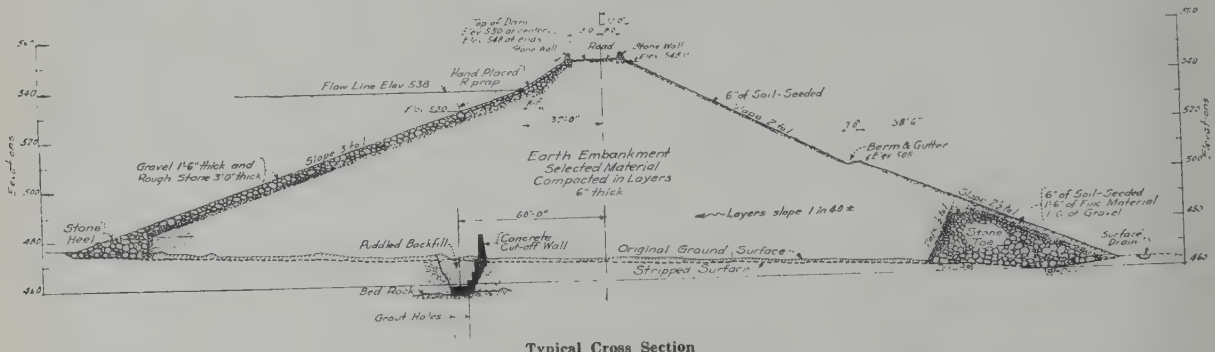
Specifications for layer filled embankments should be written to conform with the equipment to be used and the specifications should be complete and include an allowance for the compacting done by the hauling equipment. On this particular job, much more compacting is being done than was specified, but if the contractor had decided to haul the material to the dam by industrial trains or by other means, which would not give the amount of compacting equal to that represented in the tabulation, additional rolling equipment would have been required.

Numerous test pits have been dug in the embankment. Below a depth of 1 ft., it is impossible for a laborer to dig the material without the use of a pick. Laborers say that it is as difficult to dig as any natural material they have ever dug. Unfortunately, we have not at the present time, any figures which we can safely rely upon to give the amount of shrinkage of this material. At the end of this work, we will have quite definite figures for this factor.

Soil Tests.—The various kinds of soil encountered are tested in the field office by a simple method worked out by Dr. Charles Terzaghi of the Massachusetts Institute of Technology. The method involves the use of a device for measuring the capillary rise of water in soil.

Last season, 425 samples of material were tested in our field office. Of this number, 264 were of material being used in the dam embankment. The average coefficient of permeability of the 264 samples is .00007 cm. per second and the volume of voids 34 per cent. The line of saturation and the amount of leakage expected were computed on the basis of the coefficient of permeability averaging .0001 cm. per second. The material is some better than originally anticipated.

A system of pipe drains has been built underneath the stone toe, the main drain of which passes through a catchbasin just below the dam. Ditches which will collect the surface drainage on the face of the dam will discharge into this catchbasin. A weir has been built in the catchbasin so that the amount of leakage through the dam can be measured. Weirs have also been built on each brook at the head of the reservoir. During the construction period, daily records are kept of the flow of water over these weirs and also the flow of water in the brooks after they join at the mouth of the outlet conduit. If records are kept of the amount of water used from the reservoir after construction and the amount of water entering the reservoir, together with the heights of the reservoir, and the amount wasted, the approximate amount of leakage through the walls of the reservoir may be determined. Such a figure will be of particular value to check the estimates made of the leakage by the geologists.



Typical Cross Section

Miscellaneous Structures.—The lower gate house, a small structure 16 ft. by 20 ft., consisting of a concrete basement and brick superstructure, houses gates which will control the flow of water in the supply main. Provisions have been made in the layout of the piping so that the water may be returned to the brook or to an aeration plant, which may possibly be needed.

The supply main extends from the lower gate house along the brook a distance of ½ mile to a connection with an existing main. It is a 20-in. c. i. pipe laid in a trench with an average depth of 7½ ft., located on a steep side hill. The total cost of this pipe line per linear foot was about $11.50.

The spillway and spillway channel were built on the steep south bank of the valley. At the upper end, a large amount of rock flour silt was encountered and the sides of the spillway are gravity retaining walls. Sand, gravel and rock were encountered most of the distance and the slopes of the channel are paved. Rock was encountered at the lower end of the spillway where the alignment is on a curve. The channel was built in sections 30 ft. long and on chords around the curves. Movable forms were used for the slope paving. At the lower end of the channel, difficulty was had in hauling the excavated material from and hauling the construction material to the channel, as the grade here is 18 per cent. The only hauling vehicle which could operate on this grade was the Linn tractor.

A road has been excavated from an existing road to the south end of the bridge. This road will cross the spillway and the dam. A pony truss bridge with a concrete deck has been built across the spillway. The steel for the bridge was fabricated in Worcester and the trusses, 60 ft. in length, were transported via highways to the site. Only a small amount of trouble was had navigating the truck and trailer around the sharp curves approaching the job.

A considerable amount of material excavated from the road and spillway channel was not suitable for use in the embankment. This material was used for blanketing swampy places in the reservoir. In connection with the preparation of the reservoir site for the storage of water, some work has also been done stripping the flow line. Most of the material on the banks of the reservoir is sand and gravel. A Byers gasoline shovel has been used in making a single cast over cut along the flow line. This results in thorough stripping for a depth below the flow line of about 10 ft. and blanketing a similar depth below the cut. This scheme of treating the flow line eliminates a great amount of hauling of the stripping material and leaves the shores of the reservoir in a much better appearance.

General.—The contractor, the C. & R. Construction Co. of Boston, has cooperated fully at all times with the engineers on this project. The job has been exceptionally well equipped at all stages of the work. The total cost of all equipment used amounts to $124,000.

Previous to beginning the construction work which has been described, the city did a considerable amount of work in preparing for a reservoir in this location. 300,000 pine trees were planted on the watershed as a part of the reforestation work so well done in this city. Nearly all of the land in the watershed has been acquired, and all possible sources of pollution have been eliminated.

Acknowledgment.—The foregoing is an abstract of a paper presented Feb. 13 before the New England Water Works Association.

Treatment of Paper Mill Wastes

The recently issued 1928 report of Abel Wolman, Chief Engineer Bureau of Sanitary Engineering, Maryland State Department of Health, contains the following:

The investigation at the paper mill of the Congoleum-Nairn, Inc., which has been in progress for several years, was continued. Experiments were conducted on the waste treatment plant, which was placed in operation in 1927, to determine whether some other coagulant than alum might be used. During the course of the experiments, ferric chloride alone, ferric chloride plus lime, alum alone and alum plus sulphuric acid were used. The results obtained with ferric chloride were not sufficiently better than with alum to justify a change. A treatment of 90 grains per gal. of lime and 50 grains per gal. of alum produced an effluent approximately equal to that obtained with alum at the rate of 140 to 180 grains per gal. Further work along this line will be done to reduce the amount of waste still reaching the stream.

In the operation of the coagulating basins a new procedure has been used. The basins were so designed as to make it impossible to draw off all of the supernatant liquid from the tank, the outlets being 2 ft. from the bottom of each basin. Formerly, this entire 2-ft. depth was discharged to the lagoon. It is now taken from each tank to one coagulating basin where it is re-treated and re-settled. The supernatant from this tank is discharged to the stream and the resulting sludge discharged to the lagoon. The supernatant liquid from the lagoon is run off to a cinder bed and thence to a second cinder bed from which it passes to the stream. These cinder beds are 4 by 6 ft. in area and contain 5 in. of cinders and 5 in. of sand. The cinders and sand are removed and replaced with new material about every fourth day. Treatment of the cinder bed effluent with lime would produce an excellent floc and a practically water white supernatant, but this treatment has not been required since the amount of discharged waste has been very small.

Court Decision on Construction of Sewer System

Public Health Reports for Feb. 15, gives the following court decision handed down Nov. 23, 1928, by the Kentucky Court of Appeals in the case of Baker v. City of Princeton (11 S. W. (2d) 94):

Chapter 88, Laws of 1928, authorized the construction, maintenance, etc., of sewers in fourth-class cities. After this statute went into effect, the city of Princeton, a fourth-class city, passed an ordinance providing for the construction of a sewerage system.

About 20 years before, the city had constructed a small sewer system in the business section, which system served a few residences, including two belonging to the plaintiff. A fee of $20 was paid to the city for the privilege of connecting with the system, and there was no further charge.

The plaintiff instituted an action to enjoin the city from proceeding with the letting of contracts and the construction of the sewer system under the above-mentioned law and ordinance. It was insisted that the plaintiff and others who had paid the fee of $20 had acquired a vested right which the city could not interfere with or take away. The court of appeals did not take this view of the matter, saying that "The mere right to tap a sewer system in consideration of a specified fee is simply a temporary privilege which must yield when it becomes necessary to discontinue the old system, and construct a new system in order to promote the public health."

One of the other points made was that the city council was without power to create a single district but should have created several districts so that the burden would fall more equally on the property owners. Concerning this the court said that "There is nothing in the act that requires a city council to divide the city into separate districts. On the contrary, the whole matter is left to the sound discretion of the board of council (cases cited), and the courts are without authority to interfere, even though they may believe it would be more advisable to adopt a different plan."

The court concluded its opinion by saying that "the city has the power to construct the proposed sewer system in accordance with the terms and conditions contained in the ordinance."

City-County Consolidation in California

The San Francisco Bureau of Governmental Research in a recent report recommends the consolidation of the city and county of San Francisco with San Mateo County into one unit as a "city-county with adequate provisions for local representation on a central legislative body, a centralized administration of common governmental functions, and the retention of local powers and control of local functions by local units, or boroughs." The proposal has a double purpose, as do most of the proposals for metropolitan government, namely: (1) to provide adequate services for a growing metropolitan district in the way of highways, regional planning, water supply, sewage disposal, port facilities, transportation, schools; (2) to eliminate duplication of functions in, and reform faults of existing units of government. The proposed new unit would include a population of 745,000 and an area of 489 square miles.

Weighing the Probable Truth of a Theory

By HALBERT P. GILLETTE, Editor

THERE is a prevalent belief that men equally informed as to the facts are equally competent to weigh the merits of a scientific theory; but the history of science shows that a very large percentage—usually a great majority—of scientists have not been competent to appraise a new theory.

Newton's theory of gravitation was not generally accepted in Europe until long after his death. Prout's theory of the genesis of atoms from hydrogen was rejected by all authorities for nearly a century. Einstein's theory of relativity was practically ignored by scientists for 15 years after its publication. Each of these three theories was supported by quantitative evidence that should have carried conviction the instant the theory and the evidence were grasped. These three are typical of scores of quantitative theories that have had to wait decades, or even generations, before general acceptance was secured.

After making allowances for mental inertia, skepticism, egotism and all the psychological conditions that prevent an impartial and thorough study of a new theory, a good deal of mystery remains as to the slowness with which a true theory receives general approval. It will not do to attribute such slowness to commendable scientific caution, especially where the evidence was overwhelming when the theory was first announced. We must look for other reasons.

In searching for other reasons I have come upon one that seems to explain most of this phenomenon of skepticism about new theories. It is the prevalent failure to test new theories by the laws of probability. Treatises on logic usually discuss such tests in the most perfunctory manner, if they discuss them at all. Treatises on probability are often but little better, for their authors usually seem to have scant appreciation of the power of the science of probabilities in testing theories, to say nothing of its usefulness in discovering natural laws.

Of the 90 known atoms (out of the 92 that are supposed to exist) about one-quarter have atomic weights that are integral numbers. When, in 1815, Prout announced his theory that hydrogen atoms are the "bricks" of which the other atoms are built, the percentage of the then known atoms that possessed weights that were integral multiples of that of hydrogen exceeded 25 per cent. Let us assume, however, that 10 atoms in 40 exactly corresponded with Prout's theory. What was the probability of its truth? If any atom selected at random had an atomic weight that was an integral multiple of that of hydrogen, the probability that it would have such a weight merely by chance would be excessively small. But let us assume that it would be 1 in 2; or that it either would or would not have an integral weight. Then if 10 random selections from the 40 resulted in finding 10 atoms having integral weights, the probability of this happening purely by chance would be only 1 in 2 to the 10th power, or 1 in 1,004. Since there were 40 atoms, the fact that only 10 of the 40 had integral weights, would reduce the probability to 1 in 251. Even 251 to 1 in favor of a theory is overwhelming evidence; but remember that in this case we have assumed an initial probability of 1 in 2, which is far too small a ratio. All the possible weights that an atom might have other than an integral multiple of hydrogen, are so nearly infinite that we have no means of estimating them. When, therefore, we say that the chance is even that an atomic weight will be an integral multiple of hydrogen, we are grossly over-estimating that chance. Indeed so gross is our over-estimate that we are safe in saying that if even 2 atoms out of 90 have weights that are integral multiples of one another, they are almost certainly related as causes of one another, or a concomitant resultants of a common cause.

But the chemists looked only at the instances where Prout's theory seemed to fail, and never weighed the significance of the instances where it held true; so they rejected the theory for a century. Recently it has been found that where atoms have fractional weights, they are mixtures of isotropes that have integral weights. Thus chlorine has an atomic weight of 35.46 as a result of the mixture of three isotropes of chlorine whose weights are 35, 37 and 39. So the very exceptions that were cited against Prout now are seen to prove his rule.

Were this an isolated instance of the misjudging of a scientific theory by all the authorities save its originator, it should at least serve as a warning to skeptics. But it is not isolated. On the contrary, scientific history swarms with similar instances. Of course the initial evidence in favor of many a new theory is relatively weak, but actually the degree of its weakness is rarely demonstrated by an appeal to the law of probabilities. Instead, the critics merely guess that it is weak; and usually their guesses are influenced by its apparent failure to agree with some known fact or facts, rather than by its proved agreement with several known facts.

When any theory is in close quantitative accordance with even a very few facts, it is rare that it fails to show a very high degree of probability if tested by the laws of probability.

One celebrated astronomer, commenting on the slowness with which Newton's law of gravitation was accepted, says that this slowness was not surprising because Newton had not shown its accordance with very many astronomical facts. This statement is clear evidence of this astronomer's ignorance of the use of the laws of probability in testing such a theory; for, had Newton only proved that his law held true of the earth and the moon, still that proof would be very convincing to anyone familiar with the elementary principles of probabilities. But Newton's law fitted Kepler's laws so perfectly that he had thus extended it to include all the known planets; and he had also carried it far enough to explain quantitatively the height of the ocean tides. Truly it is astounding to find any astronomer hesitating to accept such proof as conclusive.

If it be argued that Newton wrote when science was in its infancy, the answer is Einstein's experience. Einstein offered in proof of his relativity theory that, by its aid, he had deduced two laws previously deduced by Lorentz, who in his deduction, had used the well established principles of electrodynamics. That alone was proof overwhelming that Einstein's relativity theory must be sound. But Einstein added one of the most spectacular tests of a theory that has ever been published. He deduced, by his theory, the 43 secs. of arc per century through which Mercury's orbital axis rotates, in excess of the rotation accounted for by Newton's laws; and his deduction agreed with the fact within the observational error. Yet this marvelous proof of his theory caused scarcely a ripple of interest in a scientific world which, 25 years later, is all agog over Einstein's latest development of the same theory. It is true that one of Einstein's original predictions was found to be correct 10 years ago, and that this awakened the attention of the scientific world. But this itself shows a surprising ignorance of what constitutes a crucial test of a theory. To predict a future occurrence accurately is certainly spectacular, but it is not a whit more difficult than to deduce from a theory a quantitative result in accordance with any known fact that was not used in deriving the theory. Einstein's deduction of Mercury's known orbital change was just as conclusive evidence of the truth of his theory as was his deduction of the amount by which a ray of light bends when it passes near the sun. That thousands of modern scientists failed to appreciate that this is so, is one of the most conclusive proofs that few of them know how to weigh evidence scientifically.

There is great need, therefore, of study of the principles of probability, and particularly of their application to measuring the worth of new theories. In a later article I will indicate the use of the science of probability in discovering natural laws.

Westchester County Planning and Park System

Some Interesting Facts on a Notable Park Development

ONE of the most notable park systems in this country is that of Westchester County, New York. An interesting account of the development and success of this work was given by Jay Downer, chief engineer of the County Park Commission in a paper presented at the 1929 annual meeting of the American Society of Civil Engineers. The following digest of Mr. Downer's paper is taken from the March Proceedings of the Society.

Outstanding Accomplishment.—"Westchester County, New York, during the past five years has made a contribution to park history, regional planning, and practical execution hitherto unmatched by any other municipality in the world in an equal period of time. Three outstanding features may be offered in support of this rather broad claim: First, the comprehensiveness of the County Park System which includes water-front and interior recreational areas and reservations, and an extensive system of interconnected traffic parkways; second, the speed of execution in the acquisition of lands, development, and construction work; and, finally, the self-supporting financial basis attained through the creation of property values and the development of revenues from special park privileges and facilities."

The County and Its Problem.—Lying just north of New York City, the County has 448 sq. miles stretching between the Hudson River and Long Island Sound. It embraces forty-five subordinate municipalities, including four cities, and boasts a total population of 500,000. Coincident with New York City's northward growth, development in Westchester County has been startling, being especially accelerated during recent years, and now along its Southern border being almost a continuation of New York City. Being of ancient origin, the various towns are connected with an extensive network of highways, many of them dating from the Colonial period—a typical rural road system. It was with such a problem that the County Park Commission had to cope.

"Scenic attractiveness," said Mr. Downer, "accessibility to New York City, and the trend of present growth strongly indicate Westchester County's future destiny as the most attractive residential area of the New York Metropolitan District. Industrial development in this area is very limited and, aside from control through zoning ordinances, the physical characteristics of hill and valley topography make Westchester less attractive for industrial invasion than the flat expanses of Jersey meadows threaded by water and rail transportation facilities.

"Broadly stated, the planning problem presented by Westchester County is that of a large satelloid area directly in the only mainland path of growth of New York City and destined to be devoted to residential purposes as its major utilization, but with local distribution and retail business districts to supply the needs of a greatly increased future population. Among the leading essentials for the planning of this area are the requirement of maintaining and enhancing the natural endowment of attractiveness for residential uses and the necessity for providing open traffic ways for the large volume of through-motor traffic between New York City and Upper New York State and New England which must necessarily pass through Westchester County."

County Park System.—By combining county parks for arterial traffic parkways, the Commission has been enabled to form the main elements of a general plan which is expected to mould the future development of the County very largely. Naturally, the general plan had to be accommodated to existing development and thus compromises from the ideal had to be effected. Certain well-defined fundamentals dictated this development, according to Mr. Downer. Among these he included the following:

"Elemental Features: Water-front parks along the Hudson River and Long Island Sound shores, and interior parks, reservations, and forest preserves providing for a wide range of recreational uses. An interconnecting system of traffic parkways.

"Economic Utilization of Land: Selection of the cheapest undeveloped lands, such as marshes, stream, and pond margins, or rocky uplands, undesirable and difficult to develop for residential or business uses, but ideal for park purposes and as such allocated to their most valuable economic utilization in the general scheme of county development.

"Adaptation to Physical Characteristics of Region: The diversified irregular and somewhat bold topography precluded conventional geometric planning. Such planning could not be rationally or economically adjusted to the physical conditions.

"Adjustment to Existing City, Town, and Village Developments: Interwoven with the foregoing was the necessity for effecting the most feasible compromises with existing conditions of the unplanned suburban growth.

"Rapidity of Execution: One of the most important elements was prompt action in acquiring lands in advance of rapidly rising values, leaving the shortest possible gap between planning and the execution of this phase of the program."

Parkways.—After showing the general layout of these parks and parkways, Mr. Downer continued:

"The north and south parkways, traversing the stream valleys in the direction of greatest traffic flow, serve the multiple purposes of open recreational areas, motor traffic routes of least resistance, the natural drainage routes of trunk sewers, and possible future locations of water supply conduits and other public utilities. The parkway reservations which include controlling strips of land on both sides of the streams also forestall the development of nuisance conditions such as developed along the Bronx River Parkway and led to its construction principally as a sanitary improvement project prior to the general county park program. The parkway system is coordinated with the older existing county highways."

The first of these parkways, Mr. Downer explained, called the Bronx River Parkway, was a joint undertaking between Westchester County and the City of New York. It extends 12 miles through the county and 3 miles within the city. About three years before this work was finished, the County adopted its expanded park program, working under a park commission of six members serving without compensation. One year was devoted to study, after which definite recommendations were made, all of which were adopted by the County Board of Supervisors and the requisite appropriations unanimously voted.

Extent of Park Development.—As a result of five years' active work, said Mr. Downer,

"The Commission has established a regional park system embracing within the limits of Westchester County, 16,671 acres of land, 140 miles of parkway routes, and 9 miles of beaches and shore lines along the Hudson River and Long Island Sound. This work has involved the acquisition of about 3,500 separate parcels of land, a large proportion of which was acquired by direct purchase from owners, thus avoiding the delays incidental to tedious condemnation proceedings.

"Coincidentally with the acquisition of land, a construction and development program has carried to completion seven new large-scale recreational developments, including bathing beaches, bath houses, concrete swimming pools,

a wide range of athletic, recreation, and picnicking grounds, three public golf courses, forest preserve areas, and a seaside amusement park embodying a unique and unusual feature under municipal operation. Under this development program 17 miles of fully developed traffic parkways have been completed giving a total of 29 miles, including the Bronx River Parkway."

Basic Practice in Parkway Design.—What Mr. Downer styled the "Westchester County type of parkway" is being recognized as the most economic solution. By establishing attractive residential zones along the roadways, valuations are greatly enhanced; this is largely in contrast with the depression of land values along trunk highways flanked by billboards. The Westchester practice is to utilize the minimum width of 200 ft., enlarging this where cheap land is available or where water-surface development is feasible. Mr. Downer continued:

"As to the motor driveways, the standard practice is to lay pavements 40 ft. wide for four lines of traffic. Grade separations have been effected at all main intersecting thoroughfares which are carried over or under the parkway drive by bridges. The rigid-frame type of stone-faced reinforced concrete bridge has been applied to the grade-separation problems with very satisfactory results both as to economy of construction and pleasing architectural adaptations. On the Bronx River Parkway the type of pavement was a concrete base with 2½-in. bituminous wearing surface, but the newer projects are standardized on reinforced concrete pavement, with asphaltic emulsion applied to eliminate glare. Grading and bridge openings are being carried through to a width of 60 ft., as the necessity for increasing the initial 40-ft. pavement width to 60 ft. in the not distant future is foreseen.

"Economics.—The park program is financed as to capital investment in lands and permanent improvements, through the standard type of county bonds running for 45 to 50 years and usually underwritten at an interest rate of 4 per cent. The yearly operation and maintenance charges are carried as an item of the general county budget raised by current tax revenue.

"From 1922 to the end of 1928, the total capital appropriations were as follows:

Acquisition of lands	$32,297,000
Improvement and construction	18,515,900
Total	$50,812,900

"Although not susceptible of exact calculation, it may reasonably be held that the creation of enhanced property valuations has fully offset the capital appropriations, regardless of the public welfare benefits of the park system. The sharp upward trend in assessed valuations immedately after the establishment of the park system is shown by the following figures:

Year	Total Assessed Valuation of Taxable Property	Increase
1921	$ 676,103,963	
1922	733,007,069	$ 56,903,106
1923	788,029,096	55,022,027
1924	891,331,983	103,302,887
1925	987,068,857	95,736,874
1926	1,143,871,106	156,802,249
1927	1,318,826,453	174,955,347
1928	1,501,531,153	182,704,700

"The influence of the park program is apparent in the increased valuations in 1924 and subsequent years. From 1924, when this influence became evident, up to and including 1928, the total increase in assessed valuations was $710,797,357. At the previous rate of increase the total for the same 5-year period would have been about $300,000,000. An increase of about $410,000,000, or about eight times the total amount of the appropriations, is, therefore, reasonably attributable to the park program."

Self-Support.—One of the outstanding results, remarked Mr. Downer, has been the attainment of a "self-supporing maintenance basis," by virtue of rentals, concessions, etc., for the use of the recreational and amusement features of the park system. He then quoted the following statistics to "show the rapid trend of earnings toward completely balancing the operation and maintenance budget:

Year	Park Operation and Maintenance Budget	Income from Park System	Net Cost of Operation
1922	$ 25,000.00	$ 272.50	$ 24,724.50
1923	54,000.00	126.00	53,874.00
1924	258,309.33	46,191.98	212,116.35
1925	529,529.99	60,944.40	468,585.99
1926	733,103.33	313,102.75	420,000.58
1927	750,125.28	462,518.98	287,606.30
1928	1,202,958.93	1,142,803.36	60,155.57

"Although 29 miles of modern parkways and an extensive system of recreational projects were in operation in 1928, the net cost of the county was only $60,155. The parkways yield no direct income, but are of incalculable value in the saving of time and in convenience and safety for the traveling public.

"An Early Success.—Although the importance of a regional park system as an item of major importance in planning for the future growth of Westchester was clearly foreseen, considerable courage was required to launch it as the largest scale improvement program ever undertaken by the county. But officials and leading citizens had full confidence that the ultimate results would amply justify the enterprise. The results which are shown by the foregoing balance sheet, frankly, have been attained in a much shorter period of time than originally was anticipated.

"The demonstration afforded by Westchester that the idealism of a well-conceived planning program may rest on a sound economic basis is providing stimulus to many other municipalities both in this country and abroad."

Parkway vs. Trunk Highways.—As any one familiar with the Westchester work would readily realize, the parkways are one of the fundamental factors. Perhaps this work is as widely and favorably known for this one feature as for any other. Certainly, these parkways seem to be one of the basic ideas or backbones of the entire work. Mr. Downer explained the underlying purpose of this part of the work, as follows:

"We are building parkways in Westchester instead of great, new trunk highways. This has been a fact which has been stressed at city planning conferences during the last two years by some of our eminent, far-thinking city planners, which is now getting into the public consciousness; the fact that we do not want to spend all our money on wide state roads, that we cannot afford to build too many super-highways, which are simply wide slabs of concrete without protection of frontages. There has been a good deal in the papers about that during the last few years, and if you knew as I do how many people are now coming to our office to study that feature—the distinction between a parkway and a broad state highway—you would realize that that is something to reckon with.

"In other words, the people are beginning to demand protection of frontages on these expensive improvements, not only that the improvement itself may be enjoyable instead of a disfigured thoroughfare, disfigured by cheap stands and billboards and tawdry business development, but that the improvement may eventually pay for itself in its influence upon the zone which it serves.

* * * * *

"New Locations Cheapest.—Another thing we have found in Westchester is that it seldoms pays to lay out a great traffic route by widening an existing road. I am speaking now, of course, of suburban areas where you have a great deal of vacant land, only sparsely developed, which could be utilized for new routes. We found in Westchester after starting out many times to widen highways, that we could always, or in most cases, get 200 or 300 ft. in back somewhere cheaper than we could get 20 or 30 ft. to widen an old highway where the frontages were improved, and where you would pay for damages in cutting off fronts of fences, front gates, dooryards, etc.

"So we went in behind, where land was donated; a great deal sold at prices below the market in order to entice the improvement. We have there not only a wide parkway instead of an 80-ft. road, but we have controlled frontages, we have a great deal of restriction on the adjoining property, and we have controlled, to a very large extent, access drives and crossings so that these can be developed as fast trafficways with the greatest margin of safety."

Pouring Asphalt Joints in Brick Pavements With a Pressure Distributor

Method Used on Recent Paving Jobs at Flint, Mich.

By H. C. McCLURE
City Engineer, Flint, Mich.

A BRICK paving job recently completed in Flint has several interesting features. The job, known as the North Saginaw St. improvement, called for a pavement 74 ft. wide between curbs. The street was paved an entire new brick surface for a portion of the distance, and with new 27-ft. strips outside of the street railway track space, for the balance. In all, paving totaled around 60,000 yd.

The specifications called for an asphalt joint filler to comply with state highway specifications for this product, the contractor finally decided on "Texaco 39" for the work

Because of the location of this job, it was deemed advisable to eliminate as much interference on the street as possible, and to reduce complaints and nuisances on the street. The suggestion was made to the contractor that he secure his asphalt in insulated tank cars, ship them directly to the engineering department siding where plant steam would be available, and then use a distributor tank truck for applying this filler. This suggestion was adopted and worked with more than the expected degree of success.

Handling Asphalt from Tank Car to Street.—The asphalt reached the plant siding at a temperature of 175° or above, and required only about four hours of plant steaming to make pumping into the distributor possible. A distributor truck, manufactured by the Hendricks Co. of Morenci, Mich., was employed for this work. This distributor carried a jacketed pump, operated from a power take-off, which not only fills the tank but circulates or discharges the asphalt, as well, by means of a 3-way valve control. The distributor also carried an air compressor, a portable coal oil torch flame, and two coal oil oil-burner nozzles for heating the asphalt when in transit to the street, or maintaining the asphalt at any desirable temperature. An ordinary fan shaped nozzle was used for applying the asphalt directly to the street, the 3-way valve being opened just a sufficient amount to give the desired quantity for the work at hand.

Joint Pouring Rapid Operation.—Three men on the squeegees were all that were required for the street end of the work, the nozzle man and truck driver being furnished with the distributor outfit. These five men handled without difficulty all of the asphalt joint material on this and some other local jobs, without any difficulty whatever and with far less actual work and inconvenience to themselves, and with far less inconvenience to the street residents than is usual in such cases. When the brick surface was laid far enough in advance, it was possible to easily pour three full tanks (700 gal. each) in a single day, and cover in excess of 2,000 yd. of surface. This pouring operation was so fast that the outfit was unable to operate for continued runs of full days, but was required to cut down to two tanks per day quite frequently. Instead of being one of the slow, cumbersome, troublesome operations, the joint pouring became the most rapid operation and least inconvenient on the job.

Advantage of the Method.—Aside from the advantages to the workmen and to the residents, we believe that the advantage to the job was without question a decided one. The material was maintained within a temperature range of less than 250°, regardless of outside temperature and regardless of the amount of material in the tank. It was absolutely uniform in every physical characteristic, no coking or continued overheating changing it in the slightest. By applying directly at the desired point, and following immediately with the squeegees, an excessive amount was not left on top of the brick surface, yet all joints were completely filled. Estimates made on numerous occasions, indicated 1 1/3 gal. or less per square yard of surface.

Unloading Asphalt from Insulated Tank Car Into Distributor Truck

During the progress of the job, sudden summer showers occurred, yet these caused no inconvenience whatever because the pouring operation could be stopped instantly; and on occasions when the rain continued, the distributor was merely drawn back to the yard and the remaining portion in the tank pumped back into the tank car. With this extreme flexibility of operation, the pouring operation could be continued at various points along the job, with only a few seconds' lost time in moving the truck ahead; and a half hour's pouring in one portion of the work required no special set-up and could just as easily be taken care of as a full day's pouring at another section of the job.

Cost of Operation.—The contractor

Applying Filler to Brick Pavement Direct from Distributor Truck. The Asphalt Is Worked Into the Joints by Means of Squeegees

was able to purchase the asphalt in tank cars at approximately $4.00 under the drum price, less 60 ct. a ton for the insulated tank cars. The distributor operator took care of the heating, transportation and applying of the asphalt—including the distributor nozzle man and truck driver—for $12.50 per ton. The three squeegee men were paid $4.50 and $5.00 per day. These items represented the entire cost of this operation on the job. There was no lost labor, even in event of unfavorable wheather, because the three squeegee men could be easily used elsewhere on the job. There was no expense of street heating, and absolutely no expense in the item of clean-up.

From the standpoint of this office, we would say that the work as we had it outlined at the start, proved to be unusually successful, both from the contractor's and city's and the residents' viewpoint. There was no more expense in taking care of the work, and the absolute uniformity, flexibility and dependability of this portion of the job recommend this method, we believe, very favorably to work of this character.

Excess Condemnation Authorized in 11 States.—Excess condemnation is already legally authorized by constitutional amendment or otherwise in 11 states.

$100,000 Traffic Survey for New York.—A traffic survey has been authorized for New York City that is estimated to cost approximately $100,000.

Cost of 48-In. Water Main at New Bedford, Mass.

During 1928 the Water Board of New Bedford Mass., constructed a 2,561-ft. extension of a 48-in. cast iron pipe for a main. The work was done by the forces of the board. The pipe was Class "C" N. E. W. W. A. specifications and cost $38.20 per ton. The following detailed costs of the work are taken from the 1928 report of the Water Board, of which Stephen H. Taylor is superintendent.

	Total	Per Lin. Ft.
Pipe and Specials and Inspection	$31,267.71	$12.21
Leadite and Gasket	881.00	.34
Tools and Repairs	3,879.72	1.51
Labor (see sub-division)	11,324.30	4.42
Fuel, Oil and Grease	1,118.21	.46
Piles and Piling	1,388.58	.54
Akron Tile Drain	1,854.93	.73
Sand, Cement and Gravel	105.40	.04
Culverts Roaring Brook	908.81	.24
Two Wooden Box Culverts	405.62	.27
	$53,134.28	$20.76
Labor Sub-division		
Unload and Distribute 48-In. C. I. Pipe	$ 606.92	$0.24
Excavation and Laying	3,565.21	1.38
Backfill	**3,428.59	1.34
Pumping	758.65	.30
Clearing	469.51	.18
Watchmen	916.21	.36
Repair of Second Hand R. R. Dump Cars	*1,197.10	.47
Miscellaneous—Line and Grade, etc.	382.11	.15

*Four second-hand dump cars purchased for $600 and repaired at an expense of $1,197.10. represent a saving of about $1,500, as compared with the cost of new cars. They have been so thoroughly overhauled and repaired that they are now in every way as good as new.

**This figure includes labor only for that portion of backfill borrowed and hauled by dump cars from gravel pit about one mile from the site. It covers the labor for excavating borrow, loading cars, hauling cars, rehandling with clamshell at the pipe and hand grading. The total borrow was 6,660 cu. yd., and it required 41 working days to handle it. Average cost, labor only, $0.515 per yard; average 162 yd. per day.

Now Building Superhighway at Washington

The newest contribution to the growing exhibit of superhighways and parkways is the Mt. Vernon Memorial Highway, which properly belongs in the latter class, soon to be built between Washington and Mt. Vernon, Va.

The Memorial Highway will be placed on a strip of land 200 ft. wide. At first, a 40-ft. pavement will be constructed, with additional hard surfacing to be laid later when traffic demands it. The roadway will be more than 15 miles long.

Grade intersections with railways and all other heavily traveled roads will be entirely avoided by means of overpasses and under-passes. Further insurance against accidents will be given by the establishment of well-kept dirt shoulders extending 10 ft. on either side of the pavement.

Another modern note will be struck in the construction of seven or eight ornamental bridges. These are to be built to a width of 60 ft., which will preclude traffic jams and accidents common to narrow structures.

By means of fast moving machinery, the highway will be completed by 1932 in time to be dedicated at the celebration of the 200th anniversary of the birth of George Washington. Work of preparing the roadbed has already started.

Landscaping will progress along with the construction work, so that shortly the builders will have achieved their purpose of making the Memorial Highway one of the most beautiful in the world. Neat parking places will be provided between the highway and the Potomac river.

Trees on Watershed Areas

A watershed-protection program initiated by the Denver, Colo., Chamber of Commerce three years ago has resulted in the planting of about 20,000 western yellow pine seedlings on watershed areas close to the city, according to a report to the Forest Service, United States Department of Agriculture. The work has been carried on with the cooperation of various young people's organizations. Last year, for example, 2,000 seedlings were planted by boys of the Order of De Molay in Red Rock Park; 1,000 by the boys of the senior class of Manual Training High School, in Dicks Park; 1,000 by the Camp Fire Girls, on Inspiration Point; and 1,000 by the Garden Club of Denver. The three years' plantings, which have been made in various locations and under varying conditions, show an average survival of about 65 per cent. These results have encouraged the forestry committee of the chamber to develop a program of planting for the whole of the city's watershed.

Essential Requirements for Adequate Street Transportation

A General Statement of the City Traffic Problem

By HAROLD M. LEWIS
Executive Engineer, Regional Plan of New York City and Its Environs

THE highway traffic problem is a new one created by developments of the last 15 or 20 years. Within this period has been the greatest growth in the use of motor vehicles. In 1895 there were only about 300 motor vehicles registered in the United States. In 1915 this had increased to about 2,500,000, and in 1926 the total was over 22,000,000. Today there are probably almost ten times as many motor vehicles used in the streets of our country as there were in 1915. The startling part of this record of growth is that it has not yet shown a downward break. There is now one car for about every five persons in the United States.

This remarkable growth in the new method of transportation has required new developments in the types, number, arrangement and functions of highways. Streets that were previously adequate have now become almost hopelessly congested, and public officials, engineering and other experts, those operating public conveyances, and the motor-riding general public are all trying to find some means of providing adequate facilities.

The traffic problem first proved too much for the old types of roadway surfaces. Waterbound macadam and other light and inexpensive road surfaces have given way to heavier and stronger pavements, not only on the main business streets, but also on that network of trunk line highways which now connects all communities of appreciable size. Only 15 years ago, dusters and goggles as a protection against dust were almost essential parts of the equipment of every motorist, who expected to have to hang on when going over the rough places in order to prevent banging his head against the top of the car. The modern smooth and dustless highway has changed all this in a remarkably short time.

Following the breakdown of highway pavements there came an inadequacy in roadway widths. As a result, trees, strips of parking and wide sidewalks have been sacrificed to permit a widening of roadways and a greater capacity for vehicular traffic. Then, to add insult to injury, we have often doubled or tripled the average heights of the buildings fronting on these same streets, with a corresponding increase in sidewalk requirements, and the excess pedestrians have had to get along on the narrower sidewalks.

In many cases, roadway widening has not proved sufficient, and expensive projects for acquiring adjacent property and increasing the widths of highway rights-of-way have often been necessary. Such costly methods cannot be continued indefinitely. Some way must be found of curing the disease without an ever continued changing of facilities laid out before the motor vehicle era.

There are two principal methods of providing adequate street transportation:

1. Better use of existing facilities.
2. The addition of new types of facilities.

He who argues that only the first of these is needed is short-sighted, and he who would depend only on the latter is extravagant and impractical. Any real solution must be based on both. A brief summary of the most important of the various kinds of facilities in each class may help to indicate how they can be co-ordinated.

Better Use of Existing Facilities

Traffic Control.—The two principal effects of early traffic congestion were delay and an increase in the number of accidents. Traffic regulation and control were instituted to alleviate these conditions. The police department being in most cases already on the job was naturally called upon to aid in such activities. Within recent years the control of street traffic by manual or mechanical means has become a specialty which has received the careful attention of experts in this particular line. The synchronized "Stop" and "Go" system has been followed by various types of progressive systems designed to permit a continuous movement.

Records of the number and speed of vehicles were made by the Regional Plan of New York and Its Environs on typical Manhattan streets in 1924. These included 983 observations over stretches of roadway from four-tenths of a mile to one mile in length. The average weighted velocity of all observations was 11.3 miles per hour. When the velocity exceeded 11½ miles per hour, the average traffic was only about 200 vehicles per moving lane per hour. This was on streets which could have carried from 400 to 750 vehicles per moving lane, depending on the roadway width and obstructions therein. This shows quite clearly that there was a considerable amount of unused street capacity in New York City at that time, which a much greater efficiency should make available.

Maximum speeds permissible have recently been increased on many of our state and county highways, where 35 and 40-mile speed limits have superseded those of 15 and 25 miles per hour. But within our cities what is needed is not so much a greater maximum speed but a greater average speed. What is gained by moving 25 or 30 miles per hour, when traffic stops and delays reduce the average speed to less than that of a pedestrian? At times of peak loads on Fifth Avenue in New York City, average vehicular speeds of 2.5 to 3 miles per hour are not uncommon, and similar conditions are found in other cities.

More study must be given to the intersections and to the movement of both pedestrians and vehicles at such points. The pedestrian has until recently received little consideration.

Truck Loading Facilities within Property Lines.—Establishments which handle a large amount of trucking are the most serious offenders in regard to the use of streets for private purposes. Large modern trucks standing in narrow roadways during the loading or unloading of merchandise are a very serious obstruction to traffic movement. In many cases the merchandise monopolizes the sidewalk space. Many large and enterprising concerns have voluntarily installed loading facilities which permit such trucks to stand upon private property. These concerns have found that the savings to themselves have justified such expenditures. This in itself indicates that the compulsory provision of such facilities would be warranted.

Similar provisions should also be made for passenger vehicles by hotels, department stores and any concerns which cater to large numbers of persons using motor vehicles in going to or from their doors.

Night Deliveries.—Even a casual study of the variation in motor vehicle traffic during the 24 hours of the day indicates the great increase in capacity which would result if the peak loads could be reduced and the traffic spread more evenly throughout the day. There are many types of wholesale products

or large deliveries of coal and other retail products which might well be delivered to the business areas during night hours.

The express companies and other concerns have long realized the savings in night trucking, and have practiced it to a considerable extent. Some large department stores move their goods at night between their main stores and warehouses, and their sub-depots in the outlying parts of the city. A more universal knowledge and practice of this type of service would do much to provide adequate daytime transportation for vehicles which must move in daylight hours.

Consolidation of Trucking.—Considerable reduction in the number of vehicles using the streets may be accomplished by a consolidation of trucking routes and trucking service. This would do away, to a large extent, with the necessity of only partly loaded trucks making their many separate trips to isolated points. Store door delivery by the railroads between their rail terminals and shipper or receiver is a useful type of trucking consolidation which has been practiced successfully in England and Canada. Joint motor truck freight terminals for L. C. L. freight is another method which would do much to reduce the number of trucks upon our city streets.

Parking.—The parking of an owner's car in front of his premises on a little used street presents no hardship to his neighbors or the traveling public, but the wholesale parking in front of anybody's property has brought about a very serious problem in the down-town sections of all American communities. The limitation of parking time by municipal ordinance naturally resulted, but has not completely solved the problem, and has emphasized the need for adequate parking facilities accessible to the business districts.

Street space is too valuable to serve as a garage. In many cases the municipalities have at public expense provided considerable areas for the parking of motor vehicles. In general, the provision of terminal storage garages, by private enterprise on the edges of the business district, seems to be the only real solution of this problem.

The Addition of New Facilities

In our developed communities we must doctor up the present highway system, as best we can, to make it serve the modern requirements. Where opportunity permits the laying out of a new street system, it can be better adapted to the motor age. The percentage of space devoted to streets in the average city is about 20 to 30 per cent and is probably sufficient. The traffic problem has arisen because this space is not properly distributed. The wholesale use of the motor vehicle, coupled with the practice of erecting tall buildings for office and other business purposes, demands that business streets be much wider than residental streets.

The checkerboard street system inflicted over large areas on so many of our American cities did not distinguish between business and residential streets, or through traffic streets and local streets. In many cases residential streets, where the use of the land is permanently fixed by zoning restrictions, can be narrower than they are today.

General Traffic Streets.—The modern street plan should distinguish between traffic streets and local residential or business streets, and design each for its prospective needs. In the residential sections the street which is not subject to the noise and inconvenience of continuously passing motor vehicles has many advantages for residential purposes. The main traffic streets should preferably run in pairs, especially where surface transit facilities are to be provided. What would it be worth to Philadelphia today if Broad St. was paralleled by a street of equal width within a few hundred feet? Many of us have been subject to long detours and delays because a main highway was under repair, and there was no adequate parallel street to which traffic could be diverted.

There is a practical limit to the widths of roadways. Within our cities four or six moving lanes of traffic on a single roadway are about the maximum desirable. Beyond that, an inefficient use of the lanes caused by a shifting of vehicles from one to the other, and the increased difficulty and danger for cross traffic, both vehicular and pedestrian, bring many disadvantages. To get the maximum efficiency of roadway space it should be divided by curbs into sections of a two-lane width, and these subdivided by lines upon the pavement into separate traffic lanes.

On highways outside the city limits, four moving lanes probably offer the most efficient facility, and where greater capacity is required, duplicate roadways are preferable to a single wider roadway.

Boulevards.—Reference has already been made to the reduction of strips of parking which has resulted from increased traffic demands. A comprehensive boulevard system is an asset which every city should attempt to gain and keep. Such streets are essential if cities are to be kept attractive in appearance, and they form the natural boundaries for residential units. A modern boulevard should have a right-of-way of not less than 160 ft., and should preferably be 200 ft. in width.

In many cases, boulevards may partake of the nature of super-highways connecting adjoining cities, such as have been developed in the neighborhood of Detroit, where a 204-ft. right-of-way has been used. Streets of this kind, linked up with by-passes around the larger communities, would form an almost ideal circulation system for long-haul vehicular traffic.

Parkways.—Parkways originally were essentially parts of the park system, and as such were mainly for local use. With the great increase in motoring as a means of individual transportation and as a recreation, the function of parkways has been expanded. As being developed in Westchester County, New York, parkways serve four purposes:

1. They provide park space for local recreation, and connect up large park areas which serve as country parks.
2. They serve as corridors of open spaces between built-up communities, and help to maintain the integrity of suburban centers with local interests and activities.
3. There are constructed through them highways reserved for passenger vehicles, and providing a pleasant and speedy means of travel between the metropolitan areas and the open country.
4. When coupled with proper zoning restrictions, they stabilize high class residential developments in attractive surroundings.

Grade Separation.—It has already been pointed out that traffic interference at street intersections is the primary cause of the inefficient use of existing roadways. This can probably be relieved to some extent by improved methods of control and better design of the intersections. A sure cure can be obtained by the separation of highway grades so as to permit uninterrupted movement in all directions. Unfortunately this method is often so costly in highly developed areas as to be prohibitive. But at certain key locations it may be expedient although costly. There are many places on the outskirts of the congested districts where such a method could be carried out at important intersections at a reasonable expense.

Realizing the great advantages of grade separation, the Topographical Bureau of the Borough of Queens, New York City, has advocated the future separation of grades by the depression of one of the roadways at many important crossings. To facilitate this, they propose the immediate acquisition of a "width of right-of-way from 130 to 160 ft. for a distance of from 300 to 500 ft. on each side of the highway intersection, for the road which is to be depressed."

Zoning and Its Relationship to Highway Facilities

Building Bulk and Highway Traffic.—Intensive building cannot be carried out over large areas without causing an impossible traffic burden on street systems already fixed by existing developments. Zoning offers about the only hope of keeping such building operations within suitable limits. There is obviously a relationship between the bulk of buildings that can be placed in a given area and the capacity of the

streets which serve as a means of access to them. Buildings of large bulk must be balanced against extremely low buildings or open spaces. But vehicular traffic caused by any building is not directly proportional to its bulk, as its type of use is an important factor. Mr. Ernest P. Goodrich, Consulting Engineer, has worked out figures showing that the relative vehicular traffic to and from buildings used for retail business, garment industry in loft buildings, and offices varies in the ratio of 4 to 12 to 21.

That this situation is realized by business and industrial leaders as well as city planners is indicated by the following quotation from an article by Mr. Irving T. Bush, president of the Bush Terminal Company, New York City:

"The sensible thing to do is to limit the floor area on each given plot. This can be done either by establishing a uniform, maximum height of building or by permitting an irregularity of height, but with the provision that a no greater number of square feet of floor space be permitted upon each lot."

An analysis by the New York Regional Plan staff of the relation between building bulk and highway traffic in southern Manhattan, New York City, indicated that if every land owner in this district were in the near future to erect buildings merely to the cornice heights, as permissible under the zoning law, there would be a volume of local traffic nearly 70 per cent in excess of that which it is estimated the streets could carry. And the setback and tower provisions of the New York City Zoning Resolution permit building bulks far in excess of those used in this computation. Therefore, if the present street system in Manhattan is to serve the buildings within the business sections, some way must be found of keeping the average height within those areas well below that now legally possible.

Influence of Land Uses.—There is a tendency to consider every arterial street as a potential business street. In many cases they have been zoned throughout for business. The result has been that property fronting on such streets has been held by real estate dealers at prices prohibited for residential purposes, and residences have first been built upon those side streets where more economical lots could be obtained. The development of property along the arterial streets has thus been held up until a sufficient residential development had taken place in the neighborhood to justify the construction of business buildings.

A more economical arrangement might have been obtained by designating certain isolated sections of the main street for small business centers to serve local residential communities. The balance of the avenue might well have been zoned for residence, with a sufficient set-back line to assure that the houses would be far enough removed from the noise and dust of the vehicular traffic to provide satisfactory places of residence.

Set-back lines are particularly valuable along streets which may later have to be widened as the area builds up and traffic increases. They permit such a widening without the costly and often prohibitive expense of tearing down buildings.

A Plan for Adequate Street Transportation.—While all cities have their traffic problems which contain many similar elements, no two cities are exactly alike, and therefore there is no standardized cure which can be applied. There are standard principles which will be of help, but their application is necessarily different. It is therefore essential that, before a plan can be adopted to provide adequate street transportation for a given community, a careful traffic survey be made for that community. The type of material to be included in such a survey is beyond the scope of this paper, in which an attempt has been made to set down some of the methods of solution which should be considered in drawing up a comprehensive plan for vehicular traffic after the survey is completed.

As has been pointed out, such a plan should combine (1) the improvement of existing facilities by new regulations, supplemental additions and such changes in existing facilities as may prove economically feasible with (2) the addition of new traffic routes adapted to modern requirements, and designed to provide for estimated future needs.

A properly prepared zoning plan can be of inestimable advantage to any community. By a careful co-ordination of its provisions with the traffic plan, it can do much to maintain a proper relationship between the buildings within a city and the streets which must both serve those buildings, and also permit an easy flow through the city of all that vehicular traffic which modern ways of living and doing business bring within its gates.

Acknowledgment.—The foregoing is a paper presented at a symposium on "Expediting and Controlling City Traffic," held under the auspices of the Engineers' Club of Philadelphia.

Percentage of Rural Population Declines.—In 1880 our rural population formed 71 per cent of the total; in 1925 the proportion was only 45 per cent. Yet there are 18,000,000 more people in the rural districts of the United States today than there were 50 years ago. Farm acreage has increased from 536,000,000 to 924,000,000, and the value of farm property is nearly five times as great as it was in 1878. Half a century ago the value of all American farm products was less than $2,250,000,000 yearly—while by 1925 it had risen to more than $13,000,000,000.

Public Purchases of Materials for Municipal Work

To the Editor: In you issue of November, 1928, I note an article on "Public Purchase of Materials for Public Works" to be furnished to contractors.

It may be of interest to your readers that the Metropolitan Water District of Manila, Philippine Islands, used these methods for many years, on certain classes of materials, especially since the extension of our system which was started a few years ago, and which will cost some eight or nine million dollars, went into effect.

Our procedure varies for various materials and is approximately as follows:

Cement: We buy large quantities of cement and test it for our own account and deliver it to the contractors at our storehouses, at practically cost price. The contractor transports it to wherever it may be needed at his own costs, and stands all losses due to damage, etc. In his charges per cubic meter of concrete, he naturally includes the cost of the cement. Cement used up every half month, as per his report verified by our engineers, is deducted from his 15-day estimate of work accomplished.

Cast Iron Pipe, Specials, Valves, Etc.: We buy ourselves under separate arrangements, and the contractor is paid whatever he bids, per ton, for transportation from our yards, installations, etc. If any material is damaged, through contractor's fault, we charge him the cost of materials.

Steel Plates for Pipes, Etc.: We purchase the plates to our specifications, and pay contractor for transportation, manufacture and construction. We intend to do this in the future with reinforcing steel, whenever large quantities are to be used. The drainage pipes for our filter system were drilled and plugged in our own shops and delivered to the contractor ready for use. We find it very advantageous, as we can secure lower prices in purchasing materials, borrow our money at about 4½ per cent, while the contractors here would have to pay 9 per cent per annum, and can buy the material we wish and avoid arguments with the contractors. The contractor is helped out considerably as it reduces his financing troubles, and does not have to worry about his materials.

We never had any trouble about non-arrival of materials on time, as we make sure to order the materials before they are needed.

A. GIDEON,
Manager and Chief Engineer, Metropolitan Water District, Manila, P. I.

Purifying Acid Mine Water

The Kaplan-Reger Process

THE West Virginia Geological Survey has recently completed a process for the purification of acid coal mine waters. Generally speaking, it consists in adding to the sulphate waters from coal mines a complex organo-metallic compound which combines with the chemical compounds of the waters and forms a blue pigment to be known as Monongahela Blue and at the same time removes the acid. By certain mainipulations the color of the pigment may be varied almost at will, producing beautiful shades of blue, green, and red. These are not aniline dyes, but are mineral pigments.

Numerous Variations Possible.—Numerous variations of the process are possible and it has not been determined which of these several manipulations may prove to be most successful or profitable, but in general the use of the process at any given point will depend on whether water purification alone is desired or whether the recovery of chemical by-products is the main consideration. In the first case, if purification is the main object, the original cost of the reagent need be no obstacle. The pigment recovered has at present a market value approximately 100 per cent greater than the reagent added and would normally be sold at a profit. If more pigment should be manufactured than can be absorbed by the market, however, it could be decomposed with the regeneration of the organo-metallic reagent and another pigment of less value recovered. By this method the organo-metallic reagent would be used many times with only a trifling loss on each operation. In the second case the more highly saturated waters would be treated for commercial recovery of Monongahela Blue and other products and water purification would be incidental although very effective.

Detailed Studies Necessary for Different Localities.—In order to determine the most practicable method of handling mine waters in different localities it will be necessary to make detailed chemical studies at all such points so that particular recommendations can be made regarding what can be done. The experiments so far made have been confined to certain mines in the Scott Run region near Morgantown, where conditions appear to be specially favorable for use of the process. It is believed, however, that the waters derived from the Pittsburgh coal of the Monongahela Valley in West Virginia, and from the same coal mine waters in western Pennsylvania and eastern Ohio will prove suitable for use in strictly commercial plants at many favorable points. So far as observed the water from the Sewickley coal has proved to be alkaline and not readily susceptible to this method of treatment. At the same time, however, this water is much less corrosive and therefore less objectionable in the streams, its principal impurities being calcium and magnesium sulphates which make it hard and troublesome for laundry and bathing purposes.

In regions where the sulphur content of the coal is very low it is not at present supposed that enough chemicals exist in the mine waters to make treatment either necessary or profitable, but further exhaustive study will be necessary to establish or disprove this theory. The Geological Survey has no present plans for work on low sulphur mine waters, as its funds and personnel are too limited to engage in a general investigation outside of the high sulphur districts.

Recovery of Chemicals Commercially Possible.—In the high sulphur regions where mine waters are acid it is believed that the recovery of chemicals will prove to be so profitable that their exploitation will be pushed by the larger mining or chemical companies to the great advantage of those concerned either by way of mine water ownership or by participation in these manufacturing enterprises, and also to the almost equally great advantage of the communities which must now make domestic use of these polluted waters. It is expected that the Monongahela Valley of West Virginia, in particular, will be specially benefited by the discovery.

The study of coal mine waters has occupied the attention of industrial and public health chemists for many years, but in general their conclusion has been that no profitable process for utilizing these dissolved chemicals could be devised and that little could be done toward purification except to neutralize the acids by the addition of lime which at the same time makes the water hard and in some respects more objectionable. Federal chemists have estimated that four or five tons of water are produced for each ton of coal mined and that in Pennsylvania alone 9,000,000 tons of sulphuric acid are dumped annually into the streams. In the Monongahela Valley of West Virginia chemists of the university have figured that the acid mine drainage of 50,000,000 gal. per day. On the basis of 200 grains of acid per gallon the river receives about 250,000 tons of acid annually. These figures give some idea of the pollution problem.

How Process Was Discovered.—In 1919 David B. Reger, now Acting State Geologist, collected a few samples of mine waters on Scott Run and had them analyzed in the laboratory of the Survey in the hope that some profitable use might be made of them, but no such result was achieved, as the Survey was then poorly equipped for such an investigation. In the summer of 1928, after he had become its acting head, the Survey installed a new chemical laboratory with facilities which made possible a resumption of the study. In August of that year Mr. Reger and Dr. B. B. Kaplan, chemist of the Survey, again began the collection of acid mine waters, which were then subjected to exhaustive analyses and experiments by Dr. Kaplan, resulting in the rapid development of the process above mentioned. To those who have been permitted to witness the production of Monongahela Blue and other valuable compounds by Dr. Kaplan in his laboratory the results are declared to be a brilliant achievement of unusual merit, capable of bringing to West Virginia a valuable chemical industry and at the same time ridding the state of a grave menace to its water supply.

For convenience it has been styled the Kaplan-Reger Process, giving first honor to its chief technician, Dr. Kaplan, and at the same time recognizing the original conception and personal cooperation of Mr. Reger. Patents are now pending in Washington to cover the process, as it is not considered advisable to permit indiscriminate or irresponsible chemical manipulations on water which may be used for city supply at some down stream point. Under proper chemical supervision there is no danger that any deleterious agent may enter the water. On the contrary the dangerous compounds now in it will be entirely removed. At some later date a detailed scientific description of the process will be prepared for the technical journals.

The Kaplan-Reger Process differs fundamentally from all other methods of treating acid water. In general the practice has been to use the so-called base exchange method which consists in substituting a less objectionable chemical for one which is distinctly injurious. This method is expensive and unsatisfactory since the chemicals are always lost and no by-products are recovered and since the highly saturated water foams in boilers and is otherwise troublesome to use. In the Kaplan-Reger Process, however, the added chemicals combine completely with the chemicals in the water to form an insoluble, marketable product, leaving the water practically free from acid and mineral substances.

Florida Water Works Men Meet in April.—The next meeting of the Florida section of the American Water Works Association will be held April 10 and 11, 1929, at Jacksonville, Fla. E. L. Filby, Chief Sanitary Engineer, State Board of Health, Jacksonville, Fla., is secretary.

The Sewage Disposal Plant of Aurora, Ill.

Design and Construction Features Outlined

By L. R. HOWSON
Alvord, Burdick & Howson, Consulting Engineers, Chicago, Ill.

THE Aurora Sanitary District was organized in 1926. The district boundaries include all of the city of Aurora and a small area outside. Quite recently, the district has been extended to the south along the Fox River in the village of Montgomery.

All of the sewage of this district drains to the Fox River, which flows diagonally through the center of the city. There is no sewage treatment now, with the exception of the Indian Creek District in the northeast section of the city, where in order to obviate the necessity of constructing an outlet sewer through deep cut, the city of Aurora constructed an Imhoff tank, the effluent from which discharges into Indian Creek and thence to the river.

While the flow in the Fox River exceeds 200 cu. ft. per second for approximately 97 per cent of each year, local nuisance has resulted from time to time and the objectionable appearance of the river due to the discharge of the raw sewage is noticeable a considerable portion of each year.

Soon after the organization of the district, engineers were employed to make a comprehensive study of intercepting sewers and sewage disposal. The investigation was made during the latter part of 1926 and the report was transmitted in March, 1927.

Population Study.—The total population residing within the district at the present time is approximately 50,000 people. The growth in population in the past has been relatively slow and gradual but in recent years, due to the influence of the Chicago suburban expansion and the greater industrial development of the district itself, the growth has been more rapid. It is believed that the population will approximate 75,000 people by 1940, 105,000 by 1950 and 170,000 by 1970.

The dry weather sewage flow at the present time is approximately 5,000,000 gal. per day, which it is estimated will increase to 7,000,000 gal. per day in 1940 and from 9,000,000 to 10,000,000 gal. per day in 1950. Analyses made of the sewage and of the wastes from the principal industries showed that it is what is usually termed "typically domestic." The industrial wastes are of relatively small importance as measured by their quality and the necessity for special treatment.

Period of Design.—In the making of the investigation, it was believed that intercepting sewers, which, for a considerable portion of the distance, must necessarily pass through the business district of the city which adjoins the river on either side, should be designed for the 1970 population of about 170,000 people.

Sewage disposal works which can be constructed on the unit plan were designed to care for 75,000 people and 6,500,000 gal. per day, the conditions forecasted for 1940.

Disposal Plant Site.—In the selection of a site for the disposal plant, the choice was largely dictated by topographical features. The low lying land in the Fox River Valley is usually limited in extent and the first available site downstream from Aurora was in close proximity to the village of Montgomery. An excellent site existed about one mile south of Montgomery, in which sufficient low lying land was available, not only for present requirements but for the indefinite future. Approximately 26 acres were purchased for the first construction. This site is about two miles south of the south limits of Aurora.

Intercepting Sewer.—The intercepting sewer is approximately 32,200 ft. in length and varies in size from 18 in. to 69 in. So far contracts have been let for 12,260 lin. ft. of 69-in., 6,270 lin. ft. of 54-in. and 370 lin. ft. of 48-in. Bids have been taken upon segment block, each bidder being required to submit a proposal on at least two types of manufactures of block. All of the sewers built to date have been constructed of the Meier block.

Perspective View of Sewage Disposal Plant of Aurora Sanitary District, Aurora, Ill.

The Meier block is a pre-cast segment block tile. The segments are single ring, vitrified tile which are formed on the bank into tile sections about 4 ft. in length. Adjoining segments have interlocking lugs which are filled with cement grout and which provide the strength necessary to hold the tile in circular shape. The tile are handled and laid in a manner similar to ordinary concrete pipe. Joints between adjacent tiles are made with cement mortar.

The experience with the Meier block to date has been quite satisfactory. The only difficulty experienced has been due to the unequal burning of the segment blocks and the variations in block, shrinkage resulting from this fact. This has, however, not been a serious difficulty, simply resulting in the necessity of using more mortar at the joints between adjoining lengths. The invert of the sewer is unusually uni-

Placing Sprinkling Filter Bottom

form as all irregularities have been taken in the top of the joint. All tile are bedded in concrete up to the springing line.

The sewer excavation has been attended by no unusual difficulties other than those incident to work of this type. It was necessary to remove approximately 7,000 cu. yd. of rock from the trench excavation. The sewer trench which parallels the river, practically the entire distance, has not involved an excessive amount of pumping, the invert of the sewer in its lower reach being slightly above river level for most of the distance.

The work to date has involved three river crossings which have been effected by the use of cast iron inverted syphons, each syphon being in duplicate or triplicate with inlet and outlet chambers so arranged as to maintain as high velocities as possible in each line in service before another line is added. Provisions are made for the blowing-off of any deposit that may accumulate in the syphons.

The sewer contracts have been let at low figures, the prices and the average cuts being as follows:

Size	Per Ft.	Average Cut. Ft.
69-in. sewer	$14.95	8.0
54-in. sewer	13.75	9.25
48-in. sewer	7.75	8.5

Manholes are of concrete and were bid at prices varying from $82.50 to $100.

Plans are now nearing completion on the additional interceptors, approximately 850 ft. of which will be of 36-in. cast iron pipe laid largely in the river bed or immediately adjoining it and below river level.

Sewage Disposal Plant.—In the preliminary investigation comparative studies were made of those means of sewage disposal ordinarily adapted to Aurora conditions. As a result of that investigation, a plant consisting of coarse screens, grit chamber, tanks of the separate sludge digestion type with mechanical equipment, sludge drying beds, pumping station and sprinkling filters was determined upon. Bids were taken in the early summer of 1928 and the work is now well over half completed.

Screens and Grit Chamber.—The coarse bar screens are of the mechanically cleaned type. The screen consists of steel bars ¼ in. by 3 in. spaced at 5/6 in. centers and with a raking device automatically controlled by the difference in water level ahead and behind the screen. As the screen becomes clogged, the cleaning apparatus makes one revolution, raking the material to a platform at the top, from which it is shoveled directly into a car.

The sewage after passing through the screen passes into a grit chamber which is of the mechanically cleaned type. The screen chamber is approximately 26 ft. square and has a normal water depth of 2 ft., giving a theoretical detention period of 2¼ minutes. The grit as it settles out is collected by a revolving mechanism of the clarifier type, but with squeegees so arranged as to push the grit to the periphery instead of the center of the basin. The grit is pushed out into the bottom of an inclined elevator provided with a mechanism which tends to carry the grit up an incline and wash out the organic matter which flows back into the sewage and thence through the plant. This grit is loaded into cars and used for filling. It is expected to be practically free from organic matter.

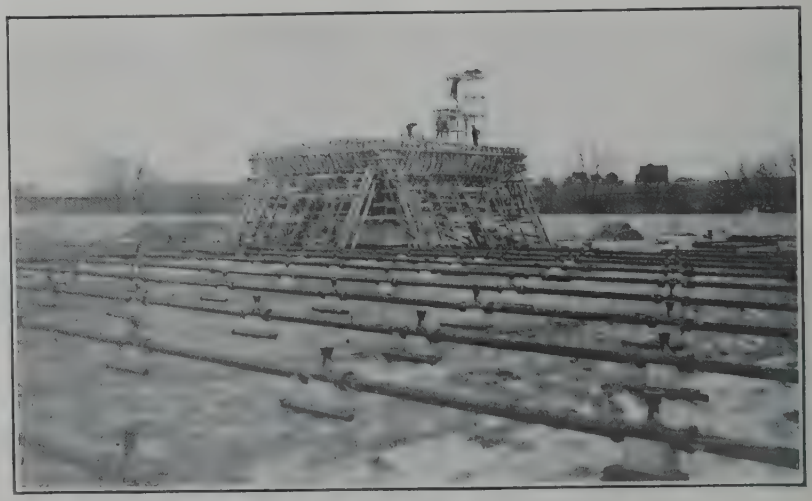
The mechanical screen and the grit chamber apparatus are furnished by the Dorr Co. The cost delivered, but not installed, is $2,450 for the screen and $5,600 for the grit chamber equipment.

The screen and grit chamber are housed in a superstructure of general architectural design similar to the office, pump house and tank structure.

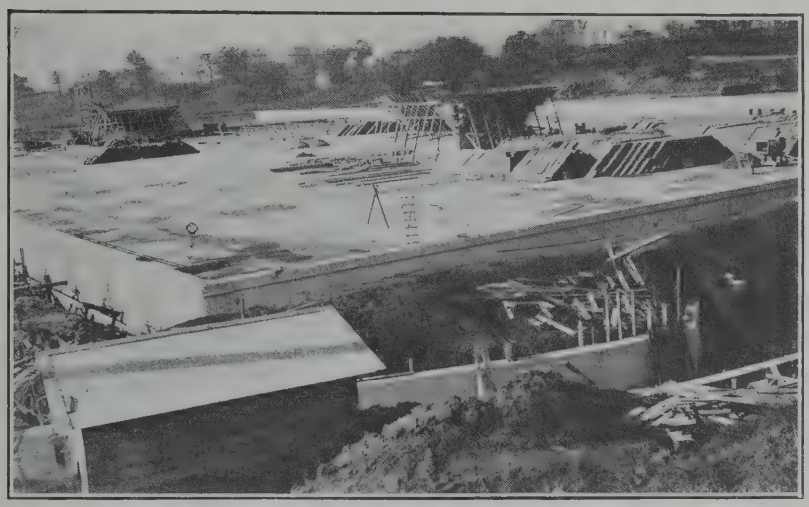
Tanks.—From the grit chamber, the sewage flows through a 48-in. sewer provided with a venturi meter to the settling tanks, which are four in number, each 50 ft. square by 11.5 ft. deep and which provide a detention period of three hours at the normal rated flow of 6,500,000 gal. per day. These basins are provided with Dorr Co.'s traction clarifiers. The tanks are provided with skimming devices for grease removal. This grease is pumped to a decantation tank in the screen house, where after separation from the water it is disposed of with the bar screenings.

The sludge is pumped from all tanks by a single sludge pump which discharges into any one of three sludge digestion tanks, each 50 ft. square by 16 ft. deep, the floor of which is placed approximately at the ground surface. These tanks provide capacity equivalent to 1.9 cu. ft. per capita served in 1940.

Gas from Digestion Process Used for Heating.—The sludge digestion tanks are covered with a concrete roof which is supported by the digester mechanism trusses and the exterior walls. The roof slopes toward a central gas dome



Sprinkling Filter, Floors, Dosing Tank and Distributors



3.6 Acres of Sprinkling Filters; Bottom and Pipe Supports Set in Background

4 ft. in diameter by 3.5 ft. high which is connected by gas piping to an ordinary gas fired hot water boiler located in the main building. The gas resulting from the digestion process will be collected and used for heating the main building and for heating water which will be circulated through the digesters to maintain as uniform and as high a temperature as practicable during the entire year.

The top of the digesters is covered with an earth fill and an embankment of earth surrounds all exposed walls. This is to assist in maintaining uniform temperature for digestion.

Each digester has a separate gas meter and all piping is so laid out as to permit of maximum flexibility of operation.

Sludge digesters may operate in parallel or series. All pumping and circulating operations are controlled from a central point.

The settling tanks which occupy an area of 50 ft. by 200 ft. are covered by a low housing of brick with stucco exterior and with a creosoted wood roof supported on steel trusses.

In plan, the pumping station, the settling tank superstructure and the sludge digestion tanks all adjoin and the superstructure is so designed that access to this entire part of the plant is had without going out of doors.

Pumping Station.—From the effluent channels of the settling tanks, the sewage flows to a suction well approximately 12 ft. by 51 ft. by 9 ft. deep. The sewage pumps, consisting of three units respectively of 6,000,000 gal. daily capacity and two of 8,000,000 gal. daily capacity, take suction directly from this well and discharge the sewage through cast iron force mains to the two twin dosing chambers. Operation of pumps is automatically float controlled. Due to the necessity of pumping settled sewage only, it is practicable to use closed impeller pumps with the resulting greater efficiencies. Each dosing chamber serves 0.9 of an acre of stone sprinkling filters. Each chamber is provided with a 24-in. single syphon.

Sprinkling Filters.—The stone sprinkling filters have a total area of 3.6 acres and an average depth of 6 ft. At the time bids were taken, alternate bids were received upon three types of underdrainage, namely, a valley and trough type of plain concrete floor, the "Rawn" underdrainage system and the "Metro" underdrainage system. As would be expected, the concrete underdrainage system was the cheapest. The Metro system bid was $9,600 per acre higher than the plain concrete and the Rawn system $11,700 per acre higher than the plain concrete The Metro system was adopted. The experience in laying this floor has been very satisfactory.

Contractors were required to submit samples of filter stone for testing. All samples were tested for soundness and ability to withstand alternate freezing and thawing, using the salt method, the immersion withdrawal and freezing method and the submerged freezing method. Of ten samples tested, but four satisfactorily met these tests which were conducted over a period of several weeks by the Engineering Service Company of Aurora.

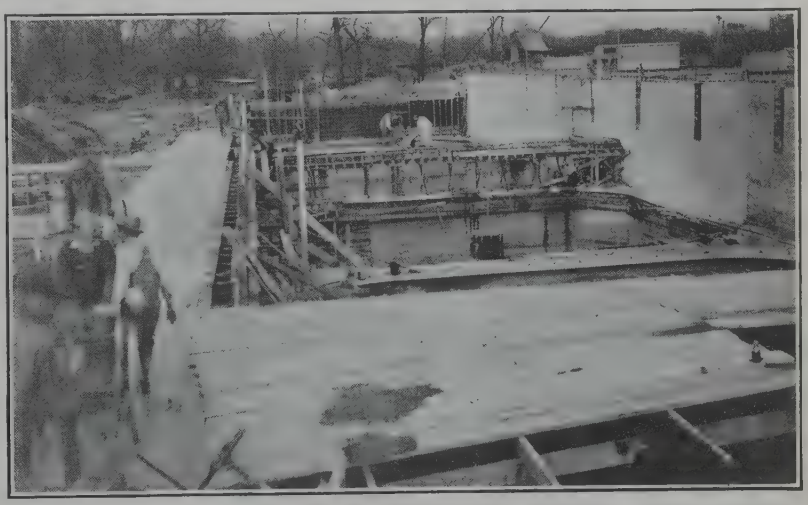
Pumping Station and Office Building.—The pumps are housed in a Spanish style building which is a part of a general structure housing the tanks proper. The pumping and administration building has a floor area of 42 feet by 76 feet. The building includes an office and laboratory, public toilets, switchboard room, heater room and two car garage. The exterior finish is of white stucco on rough brick. The roof is of Spanish tile.

Concrete Surface.—The specifications required that all concrete surfaces exposed to view should be rubbed while the concrete was still fresh with a carborundum brick. The effect thus produced has been unusually good. The writer is indebted to L. N. Fisher of Cope & Fisher of Decatur, Ill., contractors on this work, for the following construction outline:

"Various methods and times of producing the finished surface were tried. As eventually worked out, the forms are stripped in from 12 to 36 hours after pouring, all depressions and voids are then pointed up and a bush hammer is used to take off the worst of the form fins, although all ordinary form marks are left for the machine.

"In from 36 to 60 hours after the concrete has been poured, the entire surface is gone over with an air driven grinding machine. Two men are used on each machine, one to operate the machine itself and the other throwing clear water in front of the machine and pointing up with a trowel and hand brick after the machine."

The contractor advised that the cost of this finishing is from 9 ct. to 11 ct. per square foot of surface which is equivalent to about $2.50 per cubic



Pump Pit at Extreme Left; Clarifier Tanks in Center; Sludge Digesters at Right

yard of concrete based on a 12-in. wall thickness.

Mr. Fisher further advised that the best results are secured when the temperature ranges from 65 to 75 degrees. Higher temperatures result in the surface drying too quickly and with lower temperatures, the concrete does not finish up well behind the machine. If the concrete is allowed to go as long as 5 or 6 days before finishing the surface, the cost is increased approximately 100 per cent.

It is the writer's conclusion that the extra cost of this method of surface finish is well worth while. Relatively so small an amount of an intercepting sewer and sewage disposal plant construction is above ground that it is desirable to make that part as attractive as economically practicable.

Personnel.—The preliminary report, plans and specifications for the Aurora work were prepared by Alvord, Burdick & Howson. Mr. W. E. Deuchler, Chief Engineer of the Aurora Sanitary District, is supervising the construction through the Engineering Service Company of Aurora. Cope & Fisher of Decatur are contractors on the disposal plant. The intercepting sewers are being built by Ashton & Russell of Chicago and Kuehn Bros. of Aurora.

Acknowledgment.—The foregoing is a paper presented Jan. 23 at the 44th annual meeting of the Illinois Society of Engineers.

Elimination of "Red Water" with Soda Ash

After the completion of the new rapid sand water filtration plant at the Maryland House of Correction, at Bridewell, Md., considerable trouble was encountered with "red water," and tests were made to discover the cause. The recently issued report for 1928 of Abel Wolman, Chief Engineer Bureau of Sanitary Engineering of the Maryland State Department of Health, contains the following note on this work:

The tap water was found to contain appreciable amounts of free carbon dioxide and a hydrogen-ion concentration that was well on the acid side. Tests were made using sodium aluminate together with alum for coagulation and doses of 0.7 grain of alum and 0.2 grain of sodium aluminate per gallon were established. However, this did not entirely remove the trouble and further tests with lime and soda ash were made. Lime or soda ash treatment removed the carbon dioxide and increased the pH, but as the treatment with lime was less satisfatcory, due to the variable strengths of milk of lime and the danger of increasing the scale forming solids, treatment with soda ash was recommended. The recommendation was carried out and all trouble with "red water" was eliminated and improvement in the taste of the water was reported.

Cleveland Gets First Airport Convention

The first airport convention ever held will be staged in Cleveland, O., May 16, 17, 18, according to an announcement made today by Captain Clarence M. Knox, vice-president in charge of the Airport Section of the Aeronautical Chamber of Commerce. Mr. Knox, who is Commissioner of Airports of Connecticut, with headquarters at Hartford, said the airport convention would be an annual affair. His announcement follows:

"The Airport Section of the Aeronautical Chamber of Commerce will hold the first airport convention ever held, in Cleveland, May 16, 17, 18. A tentative program includes discussions and addresses on various phases of airport lighting, landing field construction and care, inter-field communication and meteorology, design and architecture, safety control, maintenance and administration, and standards of practice.

"In addition to the large attendance among representatives of airports from all parts of the United States," Mr. Knox said, "the convention will attract representatives of municipalities and civil organizations, engineers, architects, contractors and manufacturers whose interests in airport development and construction are assuming great proportions." The following have been appointed on the convention committee:

Chairmen:—Local Convention Program—Major John Berry, Manager, Cleveland Municipal Airport; Entertainment—B. E. Fulton, Manager, Fulton Field, Akron, O.; Registration—Gabriel C. Harmon, Manager, Trans-Continental Airport of Toledo; Membership—Clifford Henderson, Director of Airports, City of Los Angeles; Demonstration—E. A. Johnson, Operator Dayton Airport; Program—Harry Schwarzschild, Publisher Airports; and R. W. Whitney, Manager, Airport Section, Aeronautical Chamber of Commerce.

Information on any feature of the convention may be secured by writing R. W. Whitney, Aeronautical Chamber of Commerce, 300 Madison Ave., New York City.

Phenol Treated in New Way

The Ohio State Department of Health, according to its official publication, Ohio Health News, of March 1, has recently completed a preliminary report of an inspection of the by-product coke plant and phenol treatment works of the Pittsburgh-Crucible Steel Co. at Midland, Pa. This report is a result of one of the important departmental activities under the Ohio River Stream Conservation Agreement which is to conduct joint investigations, with representatives of other interested states, of industrial plants which discharge waste water into interstate streams or their tributaries, thus affecting down-stream water supplies.

The plant of the Pittsburgh-Crucible Steel Company is situated on the Ohio river immediately upstream from the Ohio-Pennsylvania state line and the water supply intake of East Liverpool, Ohio. The phenol-contaminated waste water from this plant, discharged to the Ohio river directly, formerly affected the East Liverpool water supply very seriously. This situation was brought to the attention of the State Department of Health of Pennsylvania by the Ohio Department of Health, and after due investigation an order was issued to the company by the Sanitary Water Board of Pennsylvania to correct the situation. As a result, this company has constructed a phenol treatment works using the Heffner-Tiddy process. This treatment works has been in operation since May 1, 1928, and it is stated that an efficiency of phenol removal of 90 to 95 per cent has been effected. In this case, the proof is in the drinking of the East Liverpool water, and in justice to the company it must be stated that so far the supply has been comparatively free from phenol tastes and odors.

It is to be noted that the waste water from the plant at Midland does not affect any water supply in Pennsylvania. The correction of this industrial waste problem was carried out at the insistence of the Pennsylvania Sanitary Water Board solely for the purpose of protecting water supplies in Ohio, West Virginia and other downstream states. The correction of this problem demonstrates the workability of the Interstate Stream Conservation Agreement on the Ohio river and indicates the benefits that may be derived by handling such matters in a co-operative manner with uniform administrative methods and policies.

Pocket Gophers Dig Up Airport

One of the finest municipal airports on the southern border, located at Douglas, Ariz., recently became infested with pocket gophers, which threw up more than 2,000 mounds of earth on the field, making the landing of planes difficult. The field is unique in that its southern border is the international boundary line between the United States and Mexico. The aviation committee of the city of Douglas requested the assistance of the Bureau of Biological Survey of the United States Department of Agriculture in clearing the field of pocket gophers and provided a crew of men to place poison and traps. Three days' work under the supervision of the bureau's leader of rodent control in Arizona resulted in complete eradication. The control operations were conducted in cooperation with the Arizona Agricultural Extension Service.

City Planning in Colleges.—There are now six colleges in this country giving city planning work as liberal arts work.

The Development of Traffic Control Engineering

New Field Offers Opportunities for Engineers

By MILLER McCLINTOCK
Director, Erskine Bureau, Harvard University, Cambridge, Mass.

THERE is probably no field of professional activity developing so rapidly as is engineering. The very great increase in the complexity of modern life, and especially in technical methods for accomplishing new results, has brought many new opportunities to the engineer during the last quarter of a century. Those who were connected with engineering practice twenty-five years ago see today the inclusion of many subjects which were never formerly contemplated as engineering problems. In no aspect are the complicated elements which come under the engineers' jurisdiction changing more rapidly than in American cities. The problem of street traffic is just one of many of the rapidly shifting conditions in current urban life. It is another instance of the important public problems which arise and need the kind of attention which engineers have been trained to give to problems of this character.

I am not going to give a technical talk tonight, or a formal one. I am going to think more or less out loud, and to tell something of the experiences I have been having the past few years, with the hope that I can give some idea of the breadth of the problem and of its character.

The Traffic Problem.—In the first place I would like to outline to you just a little bit what the traffic problem is, because while you are in the midst of it constantly it is very difficult to vizualize its influence on social life unless you have really studied it. The problem of traffic as illustrated in the streets and highways of American cities is the problem of unbalanced supply and demand, or of too great pressure in a carrying system which we have at present. We must operate arteries of travel over the street and highway systems which we have, and this is a problem, particularly in the case of such highways as have expanded very rapidly during the last few years, but which are connected with streets where the expansion has been slow.

The street system in the central part of Boston is practically identical with that laid down 100 years ago; in many parts with that of 150 or 200 years ago. It was originally designed for the needs and requirements of community necessities for travel of a small colony, using a very different type of transportation than we find it necessary to use today. We have built up on that very inadequate street system a tremendous metropolitan system, similar in size to many large cities throughout the country, and then we attempt to pour through it hundreds of thousands of people where only ten or a score or so were intended to move in the first place, and also to move them by very special type of transportation.

Problem Not New.—This is not a particularly new problem in American cities or in the city of Boston. I suppose one of the most acute traffic situations in this city was in the 90's, when traction lines were operating on Tremont and Washington Sts. As some one very aptly wrote, "We have changed the quiet streets of the city of Boston into a situation of chaos where quiet streets no longer prevail and where electric monsters crush out human lives . . .," etc. Those electric monsters have disappeared underground, which has been a temporary traffic salvation, but in the past quarter of a century the old methods of travel, particularly by means of mass transportation, have changed. We have added a torrential flood of motor vehicles.

I know of nothing so striking in the change of physical habits as the manner in which the American people have adopted, absorbed and utilized motor power. We are accustomed to hearing this past quarter of a century referred to as the age of the development of flight. We might with equal reason refer to it as the age of development in the use of the motor vehicle. It was only a quarter of a century ago that it came to stay. In that short period of time not only has the motor car developed to the efficiency of the greatest mechanical refinement, but it has been so rapidly reduced as to price of production that practically every one can own one. Almost every student of mine has at least a Ford, and I know that out in Los Angeles at least, Fords can be picked up for $25, for $15, and cars that will run, all the way down to $5. Every citizen can own a car, and they do in increasing numbers.

This last year in the United States showed a registration of about 24,000,000 automobiles—twenty-three and a half million, to be exact. Thirty years ago there were none. There are only 29,000,000 cars in use in the entire world. We have approximately 24,000,000 of them in the United States. This has changed all the transportation systems and has brought with it a problem of a very weighty character. I should like to indicate very briefly some complexities of the traffic problem as found in the typical American city.

In the first place there is the definitely social problem of automobile accidents. There were killed in the United States last year, in automobile accidents, 27,000 persons, and about 700,500 persons suffered serious personal injuries in automobile accidents. This is in excess of 1½ per cent of the entire population, to say nothing of the tremendous capital and financial loss sustained through automobile accidents. The social problem is, therefore, one of the greatest importance, and a very definite problem in connection with traffic control throughout the country. It is being met by various agencies, but unfortunately few seem to be able to make much impression on this particular part of the problem.

Economic Factor of Traffic Problem.—The second part is the economic factor, and this also is a very serious one. The cost of living and the cost of commodities depend to a very great extent upon local transportation charges. The cost of trucking within cities may amount to as much as 150 per cent of the total external transportation charges. It may cost one and one-half times as much to bring the product to the ultimate consumer as it does to bring it from its place of production to the city. Transportation has also an effect on the location of mercantile concerns. This matter of location is dependent to a very large degree on traffic congestion. It causes what we call the decentralization phenomenon, or the tendency for business to move outward. People in Boston have seen the very rapid and spectacular growth of the Park Square district, for instance. Only a few years ago there were very small and unimportant buildings located there. Today it has become an important retail center, with large buildings. This is an evidence of the tendency of business to grow outward whenever the accessibility of the location is hampered in any way. Every merchant appreciates the importance of accessibility to his business. If his store is inaccessible or traffic congests in front of his door, his accessibility results in loss of sales. People who cannot reach him will seek other markets. It is that tendency which induced Sears Roebuck to build out in the Fenway.

These are some of the aspects of this problem; some of the reasons why the agencies in American cities, interested in business, have bestirred themselves

to take very definite and direct means of dealing with the problem of traffic accidents and traffic congestion.

Planning and Traffic Relief.—I should like to tell you something about the development of the technique for handling this situation and of some of the relief measures that are being used by American cities at the present time. I want to speak first briefly about city planning and regional planning in relation to traffic relief. The traffic problem is largely the problem of too great pressure; too great demand for existing facilities, therefore since the street and highway systems are inadequate the natural relief would seem to be to build additional facilities. That is a perfectly logical answer. It is limited, however, by how far a city is justified in going in spending the necessary money. Boston, for instance, has been hesitant to build the proposed so-called "intermediate highway" for passing travel around the central and southern part of the city to the North Station area. Obviously the cities are not at an end of their traffic problems. What we see today is the indication of even greater problems to come tomorrow. For the motor car, both as the carrier of people and for trucking is so useful it is evident that its use will grow. So therefore any city which fails to grasp the opportunity for traffic relief by establishing better facilities widening the existing arteries, extending its arteries, extending new streets, through construction of traffic relief measures such as the East Boston Tunnel, is, of course, missing an opportunity which, though very costly, might easily be paid for out of the losses which accrue each year. It is difficult to give an exact figure of the losses resulting from traffic congestion. I was talking with the president of the Yellow Cab Company in Chicago a year or so ago, and he said: "Don't you think too much money is being spent on traffic relief?" I said that depended on whether it was wasting as much as the money expended in relieving the situation. He said that seemed to him doubtful. I asked: "How many trips do your cabs make into the loop district?" He told me. I said: "Suppose each cab saves a minute or suppose it loses a minute; how much time would that aggregate?" So he figured out the total number of minutes involved in the operation of his 3,800 cabs, and the number of trips. I said: "How much gasoline do they use when idle?" He figured this out, and it came to 1 gal. every 40 minutes, and at the wholesale rate he was then paying we found that one minute's delay on the 3,800 cabs making trips into the center of the city had a value of something over $100,000 in one year. That indicates how much money may be involved. In Boston one could figure up a tremendous loss which any statistician would recognize as perfectly logical to be laid to the traffic problem. So a great expenditure of money may readily be justified to bring even normal or local relief.

New Principle of Street Construction.—I am not going to talk about the proposed city planning projects of Boston. I do want to emphasize, however, one particular type of relief and particular principle of plan which seem to me most critical and important at the present time in the congested portions of our cities. You realize that so long as we have the operation of vehicles on conflicting routes on the same grade we will not get great speed. If you take Commonwealth Avenue and even widen it to twice its present width Massachusetts Avenue and other crossings, such as at Cottage Farm Bridge, will always seriously limit the activity of the arterial passes to 50 or to 30 per cent of its possible capacity. If you assume two highways meeting at grade, each one with a demand for its full capacity, and then conceive of the traffic control devices necessary to take care of alternating it fifty-fifty for each road, you will see that under the most efficient conditions the capacity of each road would be reduced to 50 per cent. Actually the capacity is reduced to 35 or 30 per cent, because in starting and stopping there is additional lost motion and lost time. It becomes quite apparent in the more congested cities, such as Boston, Chicago, New York, Philadelphia and Detroit, that we must turn to a new principle of plan in street construction if we are to use the automobile to its full capacity and speed up traffic conditions.

Development of Superhighways.—Whenever a city has reached a population of approximately 1,000,000 it has been found necessary to take the traction facilities and develop rapid transit by elevated structures or by subways. You can no longer operate on the surface because of interference. The same thing is apparent in the case of the major truck lines, and rapid transit highways are being developed with grade separation so that at no point will there be the necessity of limiting the capacity of the routes through interference of cross traffic. We would have thought that idea very futuristic only a few years ago. Now we have come to regard it as inevitable. You may be interested to know that already it has passed the phase of the theoretical. It is actually being applied. Manhattan has just made an appropriation for the construction of an elevated highway along the Hudson River, with the ultimate plan of extending it all the way to Riverside Drive. Chicago has two examples of the superhighways. It is the only city I know of where one can approach within half or quarter of a mile of the business district at an average speed of forty miles an hour. This is by outer drives along Lake Michigan. They have been constructed with grade separation, without interference of any kind. So you can come into the city at forty miles an hour without the necessity of delay because of traffic control. I think that the planning feature of the future American city, so far as the trunk lines are concerned, will be the construction of elevated streets carrying traffic without grade interference and with country highway speeds. The Bureau is now conducting a study of about half Chicago's area—the Cook County area—to find out if the elevated highways going to the north and northwest would be justified. We are going about it as an engineer would go about the location of a new bridge. We are trying to find the most strategic place to locate it, etc.

But I do want to get to my particular phase of the traffic problem—the part in which the Erskine Bureau is especially interested. About seven years ago a far-sighted student of public administration saw in the city streets a problem of great importance in the future. Seven years are not a very long time, and yet when I undertook for Professor Monro research for traffic conditions, I was able to find only two articles worthy of being catalogued as serious studies of managing traffic in city streets. Today it is difficult to pick up any technical magazine without discovering something on traffic. In that short time it has come to be a very pressing and critical public problem. When we started to study it we found in American cities a situation more or less to be expected. It was a new problem and its seriousness and future importance had not been realized. It was being dealt with as a purely political problem. Officers were assigned, right and left turns prohibited, etc. The American city ordinances were a great hodge-podge of political and city regulations, as you can imagine.

Traffic Control an Engineering Problem.—The first thing we discovered was that it was not a problem to be dealt with by the agencies attempting to handle it. It was an engineering problem, capable of being studied and analyzed and solved and regulated like any other important engineering problem. So we started on that basis and attempted to erect very primitive standards and records which would justify our presenting to American cities a claim that they should establish technical agencies to deal with this problem, then of importance and which would be of much greater importance in the future. This study has now developed into a substantial system, and many American cities have begun to study traffic problems as serious engineering problems. In the last three years there have been established in fourteen American cities traffic engineering divisions. They have established agencies for studying accidents, the causes of accidents, the physical factors involved, congestion conditions, and also are following up the limitations now applied to see whether they bring the required results. Fourteen American cities have such agencies functioning in them, rendering service

similar to that given by the water engineers in connection with the water supply, and the planning engineers in connection with city planning.

A Significant Development in Traffic Engineering.—The most significant development in traffic engineering that has taken place in any American city has recently taken place under Mr. William Williams of the Department of Public Works of Massachusetts, in the creation of the Traffic Engineering Division in the commonwealth. The act of the legislature empowering the Department of Public Works to assume very wide control and jurisdiction over traffic affairs of the entire commonwealth is of significance. This is the first time that an American commonwealth has recognized officially, through its legislature, that the problem of traffic control and vehicular control by statutes and controlling devices is one that takes serious engineering attention, and is a problem to be determined and worked out on the basis of engineering ability and knowledge. It is largely through Commissioner Williams that this act was passed, and his sympathy and earnest endeavor have furthered progress in the solution of the problem in Massachusetts.

More and more city planning agencies are coming to rely upon this technique which is being developed in determining the method in which facilities should be used. Sometimes the most elaborate facilities are not warranted in order to take care of it. I have in mind the Wacker Drive situation. The construction of this drive cost $22,000,000. We watched the construction with considerable interest, and noted two or three places where the combined congestion of traffic was too great. It was designed for horse-driven vehicles. Though it was built with a double deck and wide, it does not work at all. Traffic control devices were installed and rendered it highly efficient, with the exception of two or three portions which will have to be entirely reconstructed.

The Opportunities in Traffic Engineering.—This, in brief, is the development of traffic engineering. It does present in a rather tentative and embryonic form the new opportunity for engineering skill and science offered by this traffic problem. We are depending largely on the young engineers to develop new things, and they are developing them. This is illustrated by the construction and operation of automatic traffic signals. Five years ago there were no automatic system. Today we have the choice of half a dozen signals. The city of Boston will introduce a very comprehensive system of co-ordinate signals in the near future. Only 14 cities employ traffic officers for control purposes. It will not be more than a decade, I believe, before every city of 25,000 or over will have a traffic engineer and every state highway department will be similarly equipped. And to a similar degree in the operation of large fleets of trucks there will be at their heads those capable of ordering traffic operation. This offers an opportunity to the young engineer in a new field.

Acknowledgment.—The foregoing is a paper presented Dec. 19 before the Boston Society of Civil Engineers.

"Insulated Areas" for Relieving Dangerous Traffic Conditions

An interesting arrangement for relieving dangerous traffic conditions was mentioned by E. W. James, Chief, Division of Design, U. S. Bureau of Public Roads, in a discussion on traffic control at the 1929 annual convention of the American Society of Civil Engineers. The scheme consisted essentially of an arrangement of streets within, say an area of a square mile, whereby there would be no incentive to through traffic, although there would be every means for interior communication. Only four means of exit and entrance would be available, and the streets themselves could be of narrow width, since they would handle only local traffic.

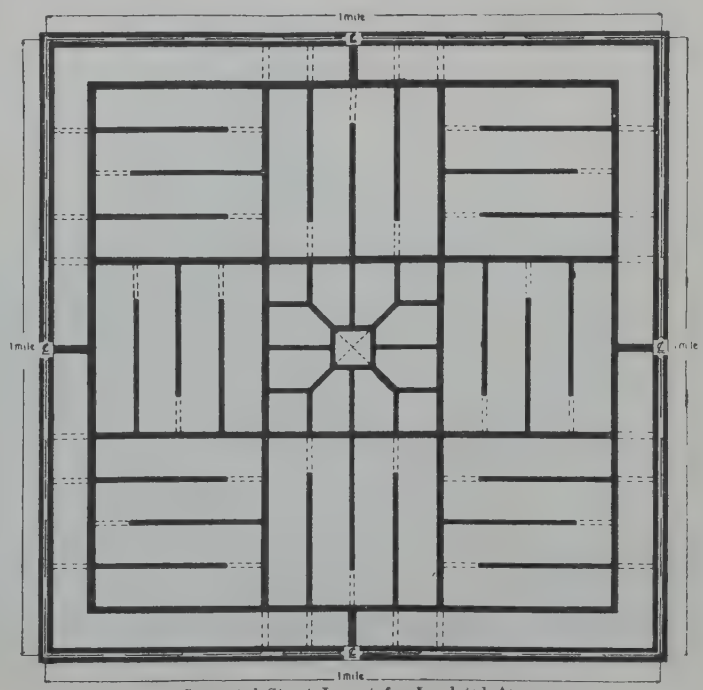
If necessary, the subdivision of such an area could be made to provide (as shown on the accompanying plan) for future extensions of through routes by cutting streets through present parks and by now providing wide rights of way for further enlargement of pavements. Mr. James estimated for such a subdivision that with "eight householders to the acre, all the traffic could leave the area on its way to work within an hour without street congestion at the exits." The interruptions by means of parks would not deter foot traffic, which could use the parkways to be provided. Such a sub-development is Radburn, near Paterson, N. J. Although the partly insulated area is only one-eighth of a square mile, it would have just about the density of population mentioned.

One particularly good feature of the idea, according to Mr. James, is its flexibility:

"Future street systems can be determined in the original layout, if it appears that the locality is likely to change usage and by a proper distribution of parks this system can be broken up and interrupted as desired so long as the area remains residential and insulated. Whenever the area is reclassified, the streets can be made continuous at no additional cost to the community for rights of way by destroying a part of the parks."

Government Statistics of the Cement Industry for February

The ratio of the operations to the capacity of the American portland cement industry during the month of February was 44.8 per cent, according to figures released March 13 by the Bureau of Mines of the Department of Commerce. During the month 8,522,000 bbl. were produced, 5,448,000 bbl. were shipped, and there were in stocks on hand at the end of the month 29,871,000 bbl. Production in February, 1929, was 3.1 per cent less, and shipments 17.0 per cent less than in February, 1928. Stocks at the mills were 9.2 per cent higher than a year ago.



Suggested Street Layout for Insulated Area

Flexible Bases for Vitrified Brick Pavements

Experiences in Mercer County, New Jersey

By HARRY F. HARRIS
County Engineer, Trenton, N. J.

SEVEN years ago the writer constructed a bituminous foundation for a short piece of brick paving. Very frankly, it was an experiment, and he could find little, if any, information to guide him in preparing his specifications as to previous practice, although it was likely that construction of this type had been attempted before.

This short paper will, therefore, be devoted to a description of the work just referred to, and a subsequent job carried out two years later, the details of which were somewhat different as to the method of constructing the base. In the first work a penetration type base was used, wherein tar was employed as a binding medium, but in the latter case the foundation was of the hot mix type of bituminous concrete. In this, asphaltic cement was utilized, to bind the mineral aggregate together, instead of tar. The first highway to be improved was located near the city of Trenton.

View of East Clinton Ave., Showing 5 Per Cent Grade, Paved with 3-in. Vertical Fibre Bricks, with Asphalt Film on Penetration Macadam Base

Conditions on East Clinton Ave. Job.—On both sides of the street, known as East Clinton Ave., there was located a large industrial plant which had buildings lining both sides of the thoroughfare. It was essential to keep the roadway, during the paving operation, in such condition that trucking and other vehicles would have access to the plant constantly, because large quantities of this company's product were shipped by trucks daily to a freight station, located about ½ mile distant.

Under standard methods, to improve the street for the character of traffic required, it would have been necessary to shut traffic off entirely while building the street, or construct the pavement and foundation under the half-width method, both of which methods were very undesirable, and would entail great losses to this large company, as it had no other means of access to and from the plant.

Preparation of Sub-base.—After giving some thought to the situation, it was decided that the use of a black base would solve our difficulties. As part of the street in question had a maximum grade of 5 per cent, it was decided to pave this section with 3-in. vertical fibre brick, using a bituminous filler. The old roadway was metalled with 4 to 6 in. of broken stone, about 20 ft. in width, and beneath this, for the most part, was a sandy subgrade. At the foot of the 5-per cent grade, the ground water level very nearly coincided with the proposed grade fixed for the bottom of the sub-base, and it was difficult to lower this by means of drains, except at certain seasons, because its height was controlled by the stage of a creek of considerable size, ¼ mile distant, and the material below the sub-base was filled with quick sand. The question of saturation of the subgrade and the material beneath presented some little problem. This low point in the grade was created in order to provide adequate headroom beneath the main line tracks of the Pennsylvania R. R., and the surface water from this sump was carried away by a pipe line laid at a gradient of approximately 0.001 per foot. To meet this situation,

View of Whitehead Road Near Trenton, N. J., Showing Industrial Buildings; 5 Per Cent Grade Paved with 3-in. Vertical Fibre Brick on 6-in. Bituminous Concrete Foundation

Sand Cushion Spread Ready for 3-in. Vertical Fibre Brick

a system of French drains was designed and these drains were tapped into the storm drain at close intervals, which plan, it was felt, would at least keep the base free of ground water when the stage of the creek was such as to permit the water to flow from the intake to outlet of the drain.

Our next problem was to obtain a binding medium for the penetration macadam base which would not disintegrate under the moisture to which this foundation might be subjected at certain times. After giving some thought to it, we arrived at the conclusion that tar would probably answer. Before laying our base, however, we decided to use the old macadam from the roadway as a sub-base. The subgrade was found to be very dry and sandy, as soon as we got away from the sump beneath the railroad, previously referred to. This sandy subgrade was difficult to shape and could not be rolled, so the stone sub-base, laid 4 in. thick, worked to very good advantage, because it not only reinforced our black base by adding additional depth, but it enabled the contractor to shape and roll his subgrade exactly to the contour desired for the base stone.

Construction Methods.—The foundation proper was built in two layers. The first was built 3½ in. deep, after compression, and of 2½-in. trap rock. To this was applied the hot tar by a pressure distributor, at a rate varying between 1.25 to 1.5 gal. per square yard. This was chipped with ¾-in. stone and rolled, after which the second course of trap rock, 2½ in. deep, was applied, making a total depth over all of base of 6 in. The latter course was composed of the next smaller size of stone, known as 1½-in. trap rock. This was penetrated with tar at the rate of 1¼ gal. per square yard, and chipped with ¾-in. stone to close up the voids and to facilitate the rolling. In other words, the base was composed of a penetration macadam pavement built close to accepted standard methods, except that a seal coat was omitted. Following the completion of the foundation, the remainder of the pavement was constructed as most other brick pavements are built. A sand cushion was applied to the foundation, and varied from ½ in. to 1½ in. in depth. After this was properly shaped, the bricks were laid with joints filled with asphalt filler. The contract price for the job complete was $5.39 per sq. yd., which was 11 per cent less than the engineer's estimate, and was divided as follows:

	Per Sq.Yd.
Excavation (Av. depth 1.1 ft.)	$0.49
3-in. Sub Foundation	.18
6-in. Penetration Macadam Foundation	2.05
3-in. Vertical Fibre Brick Surface	2.67
Total	$5.39

A traffic count taken over this road in 1924 showed an average daily traffic of 2,319 vehicles for a 16-hour day. In 1925 this had increased to 2,688, which is the last count taken, and it is quite probable that the present traffic exceeds 3,000 vehicles per day, a comparatively large part of which is composed of commercial cars.

During the building of this street, traffic was maintained throughout every working day, although there were certain periods during some of the days, where the manufacturer had to delay his hauling a matter of a few hours, which is almost negligible, when compared to what the delays and loss would have been, had some other method of construction been selected.

The Whitehead Road Improvement.—Two years later the engineering department of the county was faced with a similar condition in a nearby district. This highway, known as Whitehead Road, also passed through an industrial section, where no detours were available, and it was necessary to maintain traffic. As the experiment had worked out rather satisfactorily in the previous case, it was decided to resort to much the same methods as used before. The drainage conditions were better, however, and it was believed that if a hot mix asphalt was used for the base, instead of a penetration macadam, it could be laid quicker and to a truer surface, as some little difficulty was experienced in the former job in getting a true contour. The foundation was laid in two 3-in courses, each of which was rolled and compacted in the usual way of laying ordinary bituminous concrete pavement. It was specified that the weight should not be less than 600 lb. per square yard of completed base. When completed, it was found that it had been laid at the rate of 655 lb. The stone composing this base was of somewhat smaller size than the original job.

The Black Base.—A typical analysis of the black base mixture follows:

Screens and Sieves—Passing	Retained On	Percentage
1½ in.	1 in.	20.8
1 in.	½ in.	45.0
½ in.	¼ in.	8.0
¼ in.	10 Mesh	2.6
Stone		76.4

Laying Brick on Whitehead Road, Mercer County, New Jersey

10 Mesh	30 Mesh	4.0
30 Mesh	50 Mesh	4.2
50 Mesh	80 Mesh	4.6
80 Mesh	200 Mesh	4.4
200 Mesh		1.6
	Sand	18.8
Bitumen Content		4.8
	Total	100.0

This mixture was manufactured in a regular asphalt paving plant, located about a mile away and hauled to the job. The asphalt cement used had a penetration of between 40 and 45. It was found that the hot mixed pavement rolled to much better advantage than the penetration foundation, and it was laid for 5 ct. less per square yard than the penetration foundation, but for some unknown reason the price of brick surface was increased over the price obtained two years previous by 68 ct. per square yard. It may be, however, that the first contractor lost money on his brick surface.

Spreading Sand Cushion Over Flexible Base on Whitehead Road

Costs.—The total cost of the second job was $5.82 per sq. yd., or 7 per cent in excess of the engineer's estimate, and 43 ct. over the price obtained two years before. This price was divided as follows, on a square yard basis:

	Per Sq.Yd.
Excavation (Av. depth of 7 in.)	$0.20
4-in. Stone Sub Foundation	.27
6-in. Bituminous Concrete Foundation	2.00
3-in. Vertical Fibre Brick Surface	3.35
Total	$5.82

It should be remarked that these jobs have required no maintenance expenditures whatever, except for the repairing of a slight settlement which occured over one of the French drains in the first described job.

As a result of the experience of these two contracts, a total of 40,000 additional yards of pavement with black base was subsequently utilized, using other types of surfacing, and as an expedient for meeting difficult traffic situations with a minimum of delay in construction, it is believed that the use of black base is a big step in solving this difficulty.

In conclusion, the writer wishes to make it clear that he does not claim that the form of construction described offers a panacea for all our difficulties encountered in road design and construction, but like many other problems which all engineers meet in their practice, the remedy selected for a given ill must be adaptable to the peculiarities of the case in question, after all the factors concerned have been given proper consideration.

Acknowledgment.—The foregoing is an abstract of a paper presented Feb. 15 at the 23rd annual meeting of the National Paving Brick Manufacturers' Association.

Cleaning Well Screen with Steam

Various well water supplies in Maryland have on different occasions experienced trouble with the clogging of well screens. A study was made by the Bureau of Sanitary Engineering of the Maryland State Department on the well screens from Princess Anne to find a satisfactory method for cleaning. The results are summarized as follows in the 1928 report of Abel Wolman, Chief Engineer of the bureau:

The deposits on the inside of the screens consisted principally of iron oxide and had accumulated to such an extent as to coat almost completely over the openings, thus preventing any water from passing through the brass mesh. An attempt was made to clean the screens with (1) dilute hydrochloric acid; (2) dilute nitric acid; (3) compressed air (100 lb. per sq. in.), and (4) steam (140 lb. per sq. in.).

Both hydrochloric and nitric acid removed the deposits fairly readily, but the acids attacked the screens to such an extent that the metal was destroyed rapidly. The deposits when dry were removed rapidly and completely from the screen by compressed air, but the process is very dusty and would be inconvenient in practice. In addition, high pressure air is not available at most plants.

Steam readily cleaned the deposited iron oxide from metal and is not objectionable from the standpoint of dust formation. An inspection of the screens after steaming showed that the process was effective and almost completely removed the deposits. The method of operation consisted merely in discharging the steam through a ½-in. jet against the outside wall of the screen and then passing water through the screen to wash out of the small amount of oxide that has not been blown from the inside of the screen tube. A single screen section could be cleaned by this method in five minutes, and with a steam supply available, the cost of treatment is practically negligible.

Whitehead Road Flexible Base Ready for Sand Cushion

The Dunbar Sewage Filter Bed

Investigations at Texas Engineering Experiment Station

THE Dunbar sewage filter bed was developed in Germany by Dr. Dunbar, who built a number of installations at Hamburg and elsewhere which apparently did good work. Several beds following the Dunbar model were built in Texas during the past ten years. Inspections of the Texas plants usually revealed that, even with all the vicissitudes of operation which the small city plant must usually withstand, the effluent was fairly clear and inodorous, caused no unpleasant conditions in streams and the plants, in general, were free from nuisances. The plants, from this standpoint, appeared to have some advantage over the ordinary trickling filter.

Examination of sewage treatment literature discloses the fact that little or no study has been made of the Dunbar bed, as to its effectiveness in treating sewage, its method of operation, or its particular field of application. Accordingly, an experimental filter bed was constructed at the A. and M. College of Texas and tests of the effluent, under varying conditions of operation, were made by the Sewage Research Division of the Texas Engineering Experiment Station. The results of the investigation have been given in a bulletin issued recently by the Texas engineering experiment station, of which F. E. Giescke is director. The bulletin was writen by E. W. Steel and P. J. A. Zeller, and from it the matter in this article has been taken.

Construction of Experimental Bed.—The details of construction of the experimental bed are shown in Fig. 1. They follow, in the main, those developed by Dr. Dunbar. A 16-in. layer of comparatively fine material was supported by several layers of graded aggregate and the whole rested upon a layer of rather large material.

Sizes and thicknesses of layers beginning at the top were as follows:

16 in. layer	1/25	in. to	⅛ in.
4 in. layer	⅛	in. to	⅜ in.
4 in. layer	⅜	in. to	1½ in.
24 in. layer	3	in. to	6 in.

The bed was 4 ft. wide, 6 ft. long, and 4 ft. deep. The bottom and sides of the filter bed were constructed of wood with holes bored in the sides near the bottom, so that air might enter the lowest layer of filtering material. The bottom of the box was lined with sheet metal. An opening with a small trough at one end drained the bed, and allowed collection of samples.

In order to obtain variable rates of application of sewage to the bed, an orifice in a metal tank was used. The head on the orifice was varied by regulating the height of an overflow pipe

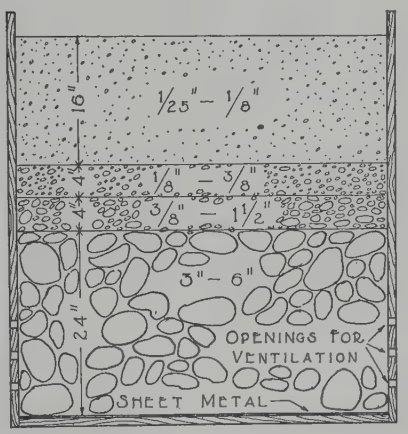


Fig. 1—Cross Section of Experimental Dunbar Filter Bed

which discharged excess sewage from the dosing tank. The orifice discharged upon a flat tile to prevent scouring the surface of the bed. The bed was located at the east side disposal plant of the A. & M. College and so placed that it received, by gravity, sewage settled in an Imhoff tank. Except for occasional clogging of the orifice during the first few runs of the bed, no difficulty was experienced in obtaining the rates desired.

Operation of Experimental Bed.—Dunbar beds are dosed by means of a trough running down the middle of the bed. The sewage leaves the trough through holes or by overflow, and percolates into the filtering material. The dosing continues until the surface of the bed is clogged, which is indicated by the sewage standing several inches deep over the bed. The bed is then thrown out of operation for rest and for cleaning of the surface.

The procedure just described was followed in the experimental work. The sewage was applied to one end of the bed directly from the orifice and allowed to spread over the surface until clogging caused the sewage to stand at a depth of 3 to 4 in.

Since the purpose of the study was to determine the efficiency of the Dunbar bed under various dosages, and to discover the most favorable rate of dosage, the experimental bed was operated at widely varying rates. Tests were made of the applied sewage and the effluent to determine the effects of varying conditions upon the bio-chemical oxygen demand, suspended matter, dissolved oxygen, free ammonia, nitrites, and nitrates. The tests extended over a period of one year, during which time the bed was operated as nearly continuously as the necessary resting and drying periods permitted. The sewage treated was stronger than the average domestic sewage which has been settled in Imhoff tanks.

Findings.—As might be expected, the quality of the effluent varied with the rate of dosing and to a lesser extent with the character of the applied sewage. Aside from these factors, no other conditions appeared to have any appreciable effect. Temperature conditions are favorable in this section of Texas and the few periods of low temperature made no apparent difference in the action of the bed. There was no pronounced falling off in the quality of the effluent during the progress of a run. That is, the bed worked as effectively after operating three or four days as it did immediately after resting.

During the investigation it soon became apparent that the practical rates of application lay between 1,000,000 and 2,000,000 gal. per acre per day. It finally appeared that 1,300,000 gal. was most suitable.

Bio-Chemical Oxygen Demand.—These determinations were made by the dilution method, using Mohlman's diluting water (i. e., distilled water containing 500 ppm. of sodium bicarbonate), and incubating for 5 days at 20 degrees Centigrade. Theriault's differential method of calculation was used in arriving at the demand.

The reduction in the oxygen demand was uniformly good, averaging 85 per cent. A very few tests showed 75 per cent, while others indicated over 90 per cent reduction. The reduction was practically independent of the rate of dosage and of the strength of the applied sewage.

The applied sewage varied from below 100 ppm. to as high as 400 ppm. in bio-chemical oxygen demand. The

amount of actual reduction varied, but the percentage reduction was practically constant. Doubling the rate of application of the sewage to the bed, that is, from 1,000,000 to 2,000,000 gal. per acre per day, produced only minor fluctuations in the percentage reduction.

The relative stability of the effluent was not determined as a routine test. A number of tests were made, however, and in nearly all cases complete stability was obtained.

The ability to reduce the oxygen demand to such a high degree under varying circumstances is an important quality of the bed as it insures good treatment of the sewage, even though the bed be overloaded, poorly operated, or the settling tanks operated inefficiently.

Nitrogen.—The reduction of free ammonia was uniformly high. Here, also, the quality of the applied sewage had no appreciable effect. High rates of application, also, lessened the percentage reduction only slightly.

Varying the rate of application had its principal effect upon the production of nitrites and nitrates. Variation in the quality of the effluent with the rate of dosage is shown in Fig. 2. For example, for a rate of 1,000,000 gal. per acre per day the effluent contained 10 ppm. nitrates, 2 ppm. nitrites, and 4 ppm. dissolved oxygen. Increasing the rate of dosage caused a decrease in all three quantities, gradually at first, but quite rapidly at 1.6 millions. Table I shows some of the data from which Fig. 2 was constructed. As might be supposed, the high rates interfered with complete nitrification. With favorable rates of application, however, an ammonia reduction of 90 per cent may be expected, with nitrites in the effluent amounting to 2 to 3 ppm., and nitrates from 5 to 10 ppm. High rates of dosage caused a very considerable drop in the nitrates with a tendency for them to hover around 1 to 2 ppm., and with the nitrites somewhat less in amount.

With the ammonia reduction remaining practically constant with varying rates of dosage, and with the nitrates and nitrites considerably less with high rates of dosage, the question arises as to the cause of the discrepancy between the ammonia nitrogen and the total of the nitrite and nitrate nitrogen. Even with the lower rates of dosage, similar discrepancies occurred, the ammonia reduction indicating a higher nitrification than was actually taking place. There may be several explanations. The nitrogen may combine with organic matter. Or, especially with the high rates of filtration, denitrification may be taking place through the agency of denitrifying bacteria. The services of a bacteriologist were not available to investigate the cause of the variations.

Dissolved Oxygen.—Fish require dissolved oxygen. The maintenance of fish life near a disposal plant outlet materially reduces mosquito nuisances. Accomplishing this has been particularly difficult in Texas, where many of the streams receiving plant effluents furnish no diluting water during the summer months. Consequently, dissolved oxygen determinations were made to discover the maximum rate of dosage at which dissolved oxygen might be expected in the effluent. Effluents containing dissolved oxygen in appreciable amounts will probably be well nitrified and stable.

With a rate of more than 1,600,000 gal. per acre per day no dissolved oxygen appeared in the effluent at any time. (See Fig. 2.) As the rate was decreased the dissolved oxygen rose rapidly, reaching 4.0 ppm. in many samples when the rate of dosage was 1,000,000 gal. per acre per day. Operating at the rate of 1,300,000 gal. per acre per day should assure enough oxygen to support the top-water minnow. Fluctuations in strength of the influent, as measured by the bio-chemical oxygen demand, showed no appreciable difference in the dissolved oxygen content of the effluent.

Suspended Matter.—Removal of suspended solids showed considerable variation under different conditions. Percentage removals tended to be greater when the suspended solids in the influent were high. The nature of the suspended matter was an important factor. When it was coarse and flocculent, removal was high; when the solids were colloidal, reduction was smaller. Varying the rate of dosage caused a variation in percentage removal, but its effect was less than that of the variation of the quantity and the condition of the suspended matter. The average removal, arrived at by considering all the runs of the bed, was about 75 per cent. In every case, the effluent from the bed was colorless and clear, in spite of the fact that the color and turbidity of the influent were frequently quite marked.

Dosage.—From the data obtained, it appears that 1,300,000 gal. per acre per day is the optimum rate. Lower rates add little to the quality of the effluent. Higher rates produce an effluent less nitrified and with little or no dissolved oxygen. (See Fig. 2.) From the standpoint of economy, therefore, it would be inadvisable to dose at rates lower than the optimum. Higher rates, however, might be permissible where some diluting water is available at all times in the stream receiving the effluent.

Low and high rates of dosage exert a considerable influence upon the length of runs before cleaning of the filter surface becomes necessary. Length of runs varied not only with the rate of application, but also with the amount and character of the suspended matter in the applied sewage. The actual volume of suspended material removed varied with each run. The conclusion reached was that the quantity of suspended matter and its physical condition have an important bearing upon the operation of the filter bed. Upon an average, the bed handled a total of 8,000,000 gal. per acre before clogging was severe enough to necessitate resting and cleaning.

Length of rest period apparently had but little effect. The rest periods were long enough to allow the surface clogging material to dry. This required less than 36 hours under average conditions, provided there was no rain. prolonging of the rest period beyond the 36 hours had no effect, beneficial or otherwise, upon the effluent produced during the next run. Cleaning of the surface preliminary to resuming operation proved to be necessary. When it was omitted, clogging occurred within 24 hours after the bed had again been placed in operation.

Cleaning Bed Surface.—The solids strained out and retained on the surface of the bed dried, in good weather, within 36 hours. They were then in the form of curled, leathery, black flakes, ¼ in. or less in thickness, more

or less detached from the bed surface, and they could easily be raked or hoed into piles and then removed. The work of cleaning a bed of practical size, say 30 ft. by 70 ft., will consume only an hour or two of an operator's time and will produce only a few wheelbarrow loads of dried solids. There is no appreciable loss of filtering material in removing the solids.

Summary and Conclusions.—The experimental work has established the following outstanding characteristics of the Dunbar filter:

1. At rates of operation up to 2,000,000 gal. per acre per day, an 85 per cent reduction in the bio-chemical oxygen demand may be expected.
2. Operation at the rate of 1,300,000 gal. per acre per day proved to be the optimum rate. It is the highest rate at which the following condition can be secured:
   (a) Good nitrification of the effluent.
   (b) High dissolved oxygen in the effluent.
3. Operation at a rate above the optimum and up to 2,000,000 gal. per acre per day will produce a clear effluent, satisfactory for many purposes, but nitrification will be incomplete and dissolved oxygen will not be present.
4. Clogging of the bed may be expected after the application of 8,000,000 gal. of settled sewage per acre of bed surface.
5. Prolonged resting of the bed between doses is unnecessary, although it apparently does no harm. Resting is necessary only to allow drying and removal of the solids caught upon the surface of the bed.

Chlorination of Deep Well Supply

Elimination of Iron Bacteria from Distribution System

By M. F. TRICE
Assistant Engineer, State Board of Health, Raleigh, N. C.

In the early summer of 1928 a disagreeable taste and odor developed in the Siler City water supply. At that time the municipal water system had been in operation three years. There had been no objection to the city water during the first year, but during the second, in the spring of 1927, a taste and slight odor developed which was easily detected. This condition existed for some two months, disappearing before the end of the summer; the one remedy applied at the time was periodic flushing of the mains. No trouble has been experienced during the winter months. With the advent of spring, however, the taste and odor returned with greater intensity, reaching a maximum last May. The citizens refused to use the city water preferring well and spring supplies. Flushing of mains was resorted to, but with little success. Samples of water sent into the State Laboratory for examination were found to be of satisfactory sanitary quality. This fact was broadcast, but to no avail, and complaints were daily piling into the city clerk's office. This was the status of the problem when an investigation was begun to locate and, if possible, to eliminate the offending taste and odor.

General Features of Water System.—The present municipal supply was constructed and installed during the summer of 1925 and was put into service in September of that year. Briefly the system consists of two deep wells, 365 and 380 ft. deep, respectively. A separate pump serves each and both discharge into a covered concrete reservoir of 200,000 gal. capacity. As an additional reserve a steel elevated tank of 100,000 gal. capacity is available. All equipment, mains, service connections, etc., were new except one pump bought second hand.

The fact that entire system was of new material made pipe growths appear an unlikely hypothesis. Contamination from an open trap door in reservoir or elevated tank or possible diffusion of mill sprinkler water into the city mains received more serious consideration as an explanation. Investigation disclosed that the trap doors to the reservoir and elevated tank, respectively, were always closed.

A textile mill, operating a sprinkler system using city water, was connected through check valves and several other industrial establishments using air filled sprinkler systems were found to maintain a constant air pressure greater than the water pressure. The air systems, too, were connected to the city system through a complicated arrangement of valves. The various mill sprinkler systems have been installed since the town supply was inaugurated, except the textile mill whose sprinkler system antedates the establishment of the town supply. Some doubt existed as to whether or not the latter should be eliminated as the source of trouble. It was eliminated for the time being as were the other industrial establishments and attention directed to the mineral and biological character of the water.

Iron Content of Water.—Ground water supplies of the state differ from the surface supplies in that practically all are hard waters and contain an appreciable and sometimes objectionable quantity of iron. The Siler City water was characteristic of all such supplies, the iron content being noticeable as indicated by housewives complaining of a brown sediment forming in kettles and pots. Field equipment did not contain reagents for an iron determination. Results of a few simple tests are as follows: pH 7.2; hardness (soap method) 81 p.p.m. and alkalinity to methyl orange 103 p.p.m.

It was observed on several occasions that in flushing mains the water flowing for the first few minutes contained a brown sediment. Every water superintendent is familiar with such occurrences and expect such to happen in sections of town where little water is used. It is often the case that water acquires a flat taste and sometimes an odor due to stagnation in a pipe line that serves few houses. This condition is immediately relieved by a thorough flushing of the mains. A great many taste and odor problems are relieved by this simple expedient. At Siler City the taste and odor persisted in spite of thorough and frequent flushings. Evidently then some pipe condition was to blame.

Samples of water from the hydrants containing this brown sediment were therefore examined microscopically for the presence of iron bacteria, as crenothrix was suspected. In several samples examined small thread-like filaments were observed. This seemed to be sufficiently conclusive that iron bacteria existed in the distribution system. As flushing had not removed the taste and odor problem, it was decided to sterilize the mains with chlorine.

Application of Chlorine. — Accordingly, an emergency chlorinator outfit was brought from Raleigh and a tank of chlorine obtained. As a heavy application of chlorine seemed advisable, it was deemed unwise to chlorinate during the day. Therefore, to inconvenience the citizens as little as possible, the chlorination was begun at eleven o'clock at night.

The chlorinator is a dry feed apparatus of the diffuser type. It was attached to the effluent from the reservoir at a point half way between that and the pump to town. With a hydrant open in town, pumping was started with strong chlorine application. A hydrant was allowed to run until a good orthotolidine test was obtained, when another hydrant was opened and the process repeated. Thus hydrants were flushed in all parts of town until the entire system was saturated with chlorine. This required about five hours, as chlorination was complete at 4:00 a. m. the following morning.

The next day the town office received many complaints, as the chlorine content of the water was sufficient to be objectionable. With the disappearance of the chlorine from the system, the taste and odor situation improved and within a week all trace of it was gone. The superintendent is positive that flushing alone would not have completely remedied the trouble, and provided that it would have been effective, the cost would have been much greater.

This is the first instance of its kind in North Carolina where iron bacteria have been satisfactorily eliminated from a distribution system with chlorine.

Acknowledgment.—The foregoing is a paper presented before the North Carolina Section of the American Water Works Association.

Sewage Treatment Plant Records at Worcester, Mass.

Careful Preparation of Records May Save Expensive Litigation

By ROY S. LAMPHEAR
Supervising Chemist, Sewer Department, Worcester, Mass.

SEWAGE treatment was first started in 1890 by the city of Worcester under an act of legislature. During the life of the old plant, the attention of the court was directed from time to time to the condition of the Blackstone River below the discharge of the Worcester plant effluent. No court action proceded very far before it was dropped. Laboratory records maintained in great detail have always been considered an effectual barrier to such court action. The city of Worcester has from time to time carried on a considerable amount of experimental plant operation. For more than 20 years operators have signed tags accompanying daily composite samples and these tags have been carefully filed upon advice of the city solicitor.

The present sewage treatment plant was placed in operation in June, 1925, in accordance with an act of legislature. The state department of public health has certain jurisdiction over the plant in case of inefficient operation. In case of action against the city of Worcester involving the sewage treatment plant, the operating records and the chemical analyses of the plant and river samples furnish the real defense or protection. The writer has perhaps gone further into this matter than seems necessary because he feels that the expenditure of a small sum of money in careful preparation and preservation of records may save expensive litigation, if ever such occasion should arise.

Record of Daily Operation.—A daily operation record form, as shown in Fig. 1, is filled out by the foreman who records all of his observations of unusual conditions in the work done. In a general way, the form is self-explanatory; blank columns are left for additional time charges, the four usual charges having been noted. The dosing tank counter readings are those at 7 a. m. of the next day, so that the Venturi meter and counters can be checked against each other when no sewage or Imhoff tank effluent has been by-passed. The operators use a notebook in which to record the meter and counter readings. When by-passing of sewage or Imhoff tank effluent occurs, the chemist has the data for determination of the quantity by-passed.

The foreman is required to record all routine operations and any measurements relating thereto, such as grit in chambers before and after flushing, depths of sludge and scum in the Imhoff tanks. If the cost of some particular work is desired, the blank time columns are used. The chemist makes any notations desired on these sheets from day to day.

Fig. 1—Form for Recording Daily Operation of Sewage Treatment Plant of Worcester, Mass.

These daily operation sheets are held in a loose-leaf cover for periods of four months and then bound in press-board for keeping as original records. Data from them are recorded each day in ink in a daily operation record and a sludge disposal record. Ready reference in detail is quickly available; nothing is entirely dependent upon memory and, in case of necessity, the records and daily operation sheets become valuable evidence in court.

A check upon the time of cleaning the screen is available, as the Venturi meter charts show the increased rate of sewage flow. A Ferguson rain gage and a snow-board furnish the rainfall and snow records. A Bristol recording thermometer registers the temperature of the air throughout the seven days of the week. These charts are carefully filed for reference. Signatures of operators and helpers are required on the same tags, which are carefully preserved by direction of the city solicitor.

Effluent Discharge.—Samples of Blackstone River water are collected once a week. The collector signs dated tags and fills out a record of observations, a copy of which is shown in Fig. 2. The tags are filed; the loose-leaf observation records are held in a cover for one year and then bound in press-board covers and properly labeled. The analyses of the river water are recorded on a printed form at the laboratory bench and transferred to the laboratory record. The laboratory forms are bound in press-board once a year.

Laboratory Records.—Laboratory bench work on plant samples is recorded in common blank books which are lettered and indexed and, when filled, are filed as original records. Routine data are recorded in the laboratory record or the laboratory daily record from day to day. Comparisons are easily made and the original records are available if desired. Four laboratory books are in use so as to prevent any delay of the work.

In addition to the laboratory record and the laboratory daily record, the supervising chemist uses two 5½ by 8½ in. note books of excellent quality, one of which contains the summary of laboratory work which does not pertain to plant operation, while the other contains results and summaries of all experimental work in the laboratory connected with plant operation as well as experimental plant operation data. In a way of research, the latter notebook is the most valuable record that is obtained.

Such completeness in the matter of records of laboratory work has been the pride of the Worcester plant for a great many years. There is only one essential record missing in connection with operation of present plant. This is a gage-house located on a prepared section of the Blackstone River channel, with apparatus for transferring river water elevations to a chart record located in the laboratory office. In the early days of old plant operation, a section of the river channel was boarded, bottom and side-walls, and charts used with a float in a well at the river bank. In later years, the boards rotted away and flood flows exceeding the height of the sidewalls covered acres of land so that accurate records were impossible.

Mr. Andrew B. Holmstrom is superintendent of sewers and the writer is in charge of the sewage treatment plant.

Regional Government in Ohio

A bill has been introduced in the Ohio legislature carrying with it a constitutional amendment providing for regional plans of government in Ohio. The constitutional amendment, in brief, permits: (1) the legislature to establish alternative forms of county government; (2) one of these forms to be an incorporated county, in which the county government would have power to control the water and sewer system, rapid transit, health and other broad powers; (3) such a county to adopt a charter only if a majority of the voters in the suburbs approve it, and also a majority of the suburbs themselves, in addition to a majority in the City of Cleveland.

Significance and Methods for Determination of Filter Plant Turbidities

Various Devices and Instruments and How They Are Used

By JOHN R. BAYLIS
Physical Chemist, Bureau of Enginering, City of Chicago, Ill.

TURBIDITY may be defined as solid particles suspended in solution, and to be more specific, particles in which none or only a part of the light will shine through. Just how small the particles may be and still be in the solid state is not known definitely, but it is evident they may be so small they do not settle rapidly from water. To distinguish between the coarser and the finer particles the term "colloidal matter" is frequently applied to the finer particles. There may be considerable difference between what the water chemist calls colloidal matter and the classification that would be given the turbidity by the physical chemist. The water chemist means suspended matter that is so finely divided it does not settle rapidly.

The suspended matter almost invariably has a specific gravity considerably greater than that of water, and it seems evident there must be some factor tending to neutralize the action of gravity. An English botanist, R. Brown, discovered in 1928 that small particles suspended in solutions were in a constant state of motion*. This is called the brownian movement. I do not know that Brown offered an explanation as to the cause of this movement, but it is now conceded to be caused from a bombardment of the particles by the molecules or electrons of the solution that are in a state of rapid motion. It is believed that this is largely responsible for the slow settling of the fine particles, especially those known to have a specific gravity much greater than that of water.

Sizes of Particles.—Crystalline particles 5 micra (Micra is the plural for micron. One micron is 0.001 mm.) in diameter or larger will settle fairly rapidly when suspended in water, and if we were concerned with particles this size or larger there would not be much need for filtration to clarify water, for it would likely be cheaper to settle the suspended matter in reservoirs. It is possible to make a suspension that probably will never settle, India ink being a good illustration. Some years ago the writer kept a bottle of water that originally had a turbidity of 5,000 standing without agitation for 5 years and it still had a turbidity of 15 to 20. This, however, is the exception and not the general rule, for most turbid waters will become fairly clear when allowed to stand in bottles for a few weeks.

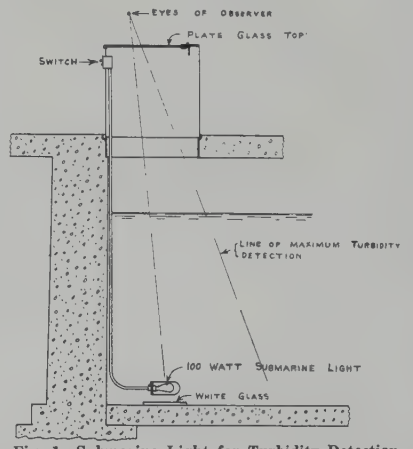

Fig. 1—Submarine Light for Turbidity Detection

It is believed that very few particles of solid matter below 0.1 micron in diameter occur in most surface waters. It is really the particles between the size of 0.1 micron and 2 micra that concern us most. This happens to be about the size of most of the bacteria that occur in water. Should a particle 3 or 4 micra in diameter happen not to become entrapped in the coagulation of chemically treated water it likely would be filtered out, but a particle 1 micron in diameter or less not entrapped has a fairly good chance to pass through the filter. Now if this particle happens to be a bacterium it also has a very good chance to pass the filter.

It cannot be stated that bacteria are removed in direct proportion to the turbidity removed by filtration, for it is known that they are not, but it is in the same direction. If the turbidity of the raw water was 100 and the number of bacteria were 1,000 per cc., reducing the turbidity 99 per cent probably would not reduce the bacteria more than 90 per cent, whereas reducing the turbidity 99.9 per cent may reduce the bacteria 99 per cent. It is evident that the actual results may vary greatly from these figures for different waters, yet they are not so greatly in error for average results. They are given more to illustrate the point than to state actual efficiencies that may be expected.

Turbidity Removal as Index.—Turbidity removal may be used as an approximate index of bacterial removal, and while not very accurate it has the advantage that it can be determined immediately whereas it is necessary to wait 24 hours for bacterial counts and 4 to 5 days for B. coli determinations. It is necessary to know something about how the bacteria usually run in the water to predict the bacteria that may be expected from the clarity of the filtered water, but after one or two years' operation of a filter plant where accurate turbidity measurements have been made results may be predicted fairly closely.

If reducing the turbidity to 1.0 by filtration reduces the bacteria 90 per cent and reducing it to 0.2 reduces the bacteria 95 to 98 per cent, it seems that this increased efficiency is well worth while for polluted waters. These are really conservative figures and may be expected at most any filtration plant.

What Operating Records Showed.—Several years' operating records at the Baltimore filtration plant after it was first put in operation revealed irregularities that were surprising. Having no accurate turbidity measurements on the filtered water it was difficult to place responsibility for the erratic results. We were really quite anxious to improve the quality of the filtered water, for the chlorine required to make the water safe was so high that chlorine tastes were frequent. Every possible cause for the erratic results was investigated, and nothing seemed to offer an explanation unless it was due to the water not being filtered perfectly clear at times. Turbidity measurements on the filtered water were being made at that time by comparing the water with standards of known turbidity in ½ gal. bottles. Our lowest standard was turbidity of 3.0, and I presume any turbidity less than about 2.0 was usually recorded as being zero, especially as we were anxious for the records to show zero readings. It may be possible to detect a turbidity of 1.0 in bottles by making very careful observations, but the average laboratory worker is usually not so careful.

To see if any relation could be established between the clarity of the filtered water and the bacterial removal, turbidity measurements were then made as carefully and accurately as it was possible to make them by bottle comparisons. It was soon found that very poor bacterial removal coincided very closely with slightly turbid water. This pointed to the need of more accurate

*Brown, R., Phil. Mag., 4, 161. (From Bancroft's Colloidal Chemistry.)

turbidity measurements on the filtered water. Then began the effort to perfect some device for estimating low turbidities. Perfection of suitable instruments was not accomplished in a few days or a few months. In fact the work was started in 1918 and it was not until 1921 that success seemed assured.

Developing Turbidity Detecting Devices.—Perhaps it might be well to review briefly some of the early work. It was soon found that there was need both for a laboratory instrument where the turbidity could be measured accurately and for some kind of device for installation on individual filters. Many devices were tried, mostly of our own conception, and considerable money expended. While on a trip in 1918, Mr. Armstrong, filtration engineer of the Baltimore plant, saw a submarine light in the clear water reservoir of the Cincinnati plant. My memory may not be correct as to it being this plant. Immediately he had one installed in the clear water reservoir of the Baltimore plant. This was a great revelation, for the water was frequently so cloudy that we were undecided at first whether to leave the light where it might be observed by all, or to put it in some place where only certain employees would have access to it. It might be said that some such device is almost an essential for every filtration plant if a uniform quality of water is desired. It does not take the place of the instruments that will be described later, for each device serves its own specific purpose. A very good arrangement of the light is shown in Fig. 1.

After installing the light in the clear water reservoir it was thought at first that the light would answer the needs of the filter operators so that as soon as the water showed a slight cloudiness the chemicals could be increased. But it was soon found that increasing the chemicals did not always clear up the water. Finally this was found to be due to flocculated matter passing the

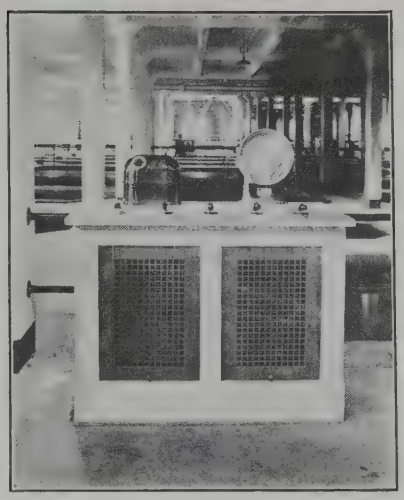

Fig. 3—Floc Detector Mounted on Filter Operating Table

filter beds that were allowed to run 100 to 200 hours between washings. The last half of the time in service frequently passed a large percentage of the coagulated matter going on to the beds. Fortunately the coagulated matter was settled out quite low before the water went to the filters, otherwise the filtered water would have been quite turbid at times from this cause. There was a belief some years ago that a certain amount of the coagulated matter should go to the filters to make them function properly, and that the coagulated water at Baltimore was being settled too clear. The water was settled to a turbidity of 2 to 5 when alum was used for the coagulant. Experiments later proved that for this plant the clearer the water going on to the filters the better.

When it was found at Baltimore that flocculated matter was passing the beds orders were issued to allow filters to run not over 36 hours between washings regardless of the loss of head. Under this order filters were being washed with losses of heads of only 3 to 4 feet in the colder months. However, it prevented flocculated matter from passing the beds. Then when the water showed a slight turbidity in the clear water reservoir it could be attributed to insufficient chemical treatment and increasing the chemicals usually caused it to clear up. A fixed limit on the time between washings could not be regarded as ideal operation, yet it was the best that could be done at the time.

Device for Detecting Flocculated Matter.—In addition to the work which was under way on the laboratory device for making quantitative turbidity determinations, work was started on a device for detecting the flocculated matter which might be installed on the individual filter units. On two occasions it was thought that something had been perfected that would answer the needs of the filter operators. A few of the filters were equipped with the devices only to find that they would not work satisfactorily.

It would be too long a story to relate all the developments leading up to the perfection of the floc detector for installation on filter operating tables shown in Fig. 2 and 3, and the laboratory instrument shown in Fig. 4. Fig. 2 illustrates a homemade instrument and Fig. 3 one along the same lines as manufactured by one of the filter manufacturing companies. A suitable floc detector was developed first. It gave very sensitive detection of the flocculated matter passing the filter beds, but did not give quantitative determinations. A device somewhat similar to the one shown in Fig. 2 was constructed for use in making quantitative determinations. This is shown in Fig. 5. About the only difference is space for two flasks, one of them to contain a standard of known flocculated matter. Quantitative estimation of the flocculated matter has not grown into favor, and there are only a few plants in which sensitive devices have been installed on the filter operating tables. Perhaps there are many waters where such devices are not needed; however, it is believed that there are many plants where they would be of great aid and for some waters they are almost an essential.

Specific Purpose of the Floc Detector.—The floc detector is not much good for observing the fine turbidity, for a fine turbidity of 0.5 to 1.0 cannot be detected. It is very sensitive though for flocculated matter. Particles that would not produce a turbidity of 0.01 are readily detected. The specific purpose of the floc detector is as the name implies, to detect suspended flocculated matter passing filter beds. It is better that it is not so sensitive to the finer particles for it would be more difficult to detect flocculated matter passing the beds. It is very important that the kind of turbidity passing the filter bed be known. If it is flocculated matter

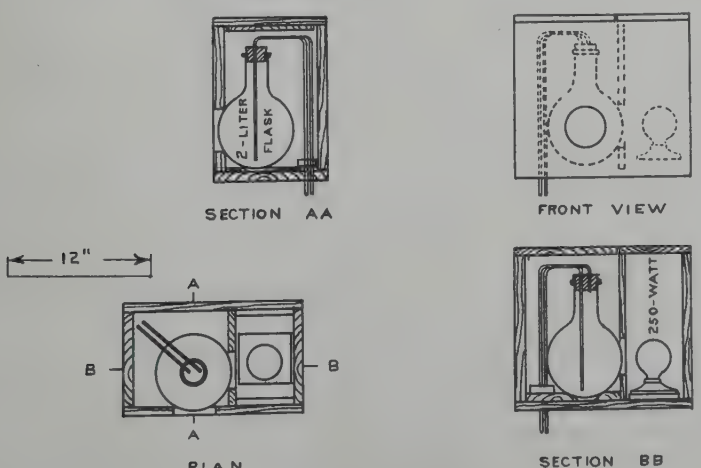

Fig. 2—Floc Detector

the filter should be washed, whereas if it is fine turbidity the chemicals should be increased.

How Turbidity of Filtered Water Was Controlled.—It might be well to relate how the turbidity of the filtered water was being controlled at Baltimore by the plant operators while the writer was there. The filter operators kept a close watch on the submarine light in the clear water reservoir and also made frequent observations in the floc detectors located on the operating tables. If the light in the clear water reservoir showed a slight cloudiness all filters were examined. If none of them showed flocculated matter passing, or so little that it was evident that this could not be responsible for the cloudiness the matter was reported to the chemical controller attendant who had instructions about increasing the chemicals. If the chemist was on duty it was also reported to him so that he might give additional instructions if necessary.

A turbidity of 0.2 is readily noticeable in the clear water reservoir if the light is under 6 or more feet of water and is near a concrete floor or some other dull surface. Just why a dull surface like that of concrete gives better detection of the turbidity is not known, but it is a fact nevertheless. Some have made the mistake of having a white surface on the bottom of the reservoir with the belief that it would show the cloudiness better. A white surface is all right directly under the light as shown in Fig. 1, but the white surface should not be more than 18 to 20 in. in diameter. Another mistake that is frequently made is not providing enough space around the light. The light may be near a side wall but there must be plenty of space away from the wall. What is seen is a reflection of the light from the particles in suspension and it is evident that the particles must not be directly over the light. Looking at an angle of 10 to 20 degrees from a line direct to the light seems to give the best results when the eyes of the observer are 8 to 10 ft. above the water surface. In other words, the area of the most sensitive turbidity detection is a circle around the light and not the area directly over the light.

The light in the clear water reservoir is just as indispensable as the floc detectors, for it is at this point where water that has not received sufficient chemical treatment is first detected. The light should be located where the water can be observed shortly after it has passed the filters, otherwise it will take a longer time to get the treatment corrected. It is true that water greatly undertreated may be detected by skilled operators after it passes the mixing basin, but slight undertreatment which will cause the turbidity to increase a little in the filtered water cannot be detected until after it passes the filters.

The Laboratory Turbidimeter.—The purpose of the laboratory turbidimeter shown in Fig. 4 is for making accurate quantitative measurements. It was selected as the most suitable means of measuring the turbidity of filtered water after many devices had been tried. A practical instrument must not be too cumbersome and it must give comparisons easily distinguished; that is, it must give comparisons whereby a turbidity of 0.2 is readily distinguished from a turbidity of 0.1 or 0.3. The first attempt to measure low turbidities was to pass rays of light through water in a dark room, somewhat in the principle of a Tyndall meter. The results were none too encouraging or at least it did not seem that an instrument along this line would be practical for routine turbidity measurements. Long tubes with a light underneath were tried next. An instrument using two-inch glass tubes 5 ft. long was constructed. This was a little improvement over the way turbidity measurements were being made in bottles prior to this time. On the basis of the long tube experiments eight of the filters in the plant at Baltimore were equipped with iron tubes about 8 ft. long, having a glass plate at the bottom and a light underneath the glass. This was prior to the perfection of the floc detector. It was soon found that turbidities readily noticeable by the light in the clear water reservoir could not be distinguished in the long tubes.

Even though the long tubes for the filters were a failure, use of the device containing the 2-in. glass tubes was continued in the laboratory. It was at least better than comparing with standards in bottles. Perfection of the floc detector suggested that a side light for the tubes might be better than one underneath. Various arrangements of the light and the tubes were then tried. Finally an instrument along the lines of that shown in Fig. 4 was tried. The glass tubes used at first were the 75 cm. tubes for the Jackson candle turbidimeter. This did not give very good results. Then colored light were tried, which finally led to the present instrument. So many things had been tried and resulted in failure that many things were being tried with not much idea of what might be expected. Blue is not the only colored glass that may be used, but blue is a color in which variations in the shade are easily distinguished.

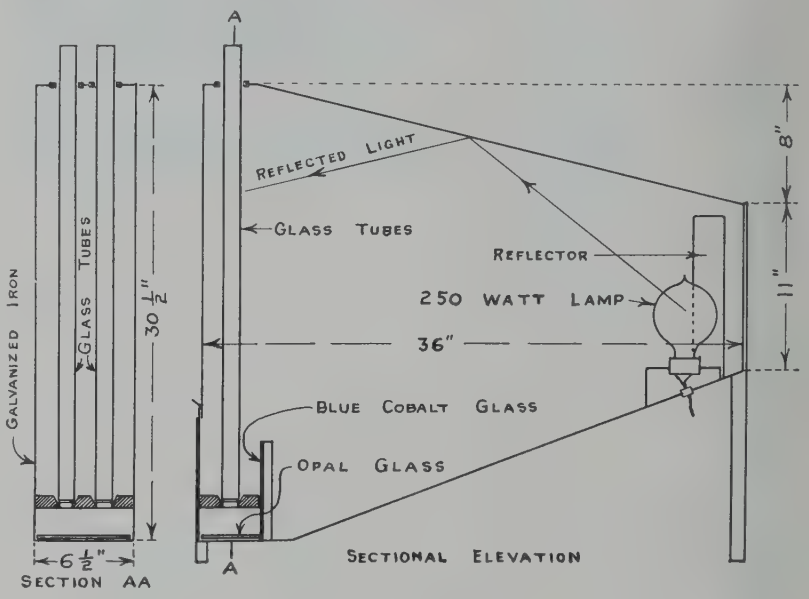

Fig. 4—Details of Turbidimeter

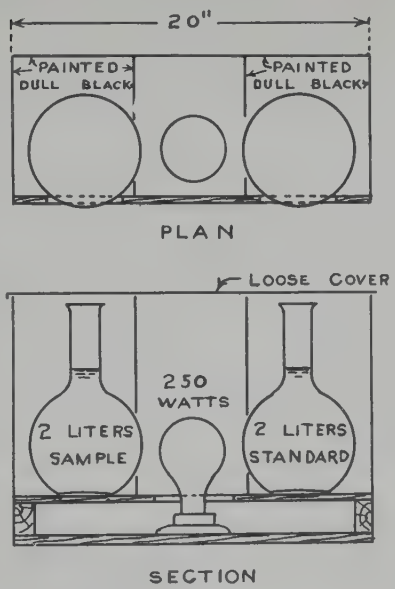
In attempting to make the instrument extremely accurate for low turbidities the range it covers is not great. The most accurate comparisons can be made when the turbidity is between 0.0 and 1.0, but it is suitable for comparisons up to a turbidity of 2.0. Some are of the opinion that if it had been made a little less sensitive and covered a wider range of turbidity that it would be more useful. This may be true, but when it is desired to produce water in which the turbidity is not more than 0.2, it seems that something in which a turbidity of 0.1 may be readily detected is desirable. There is no fault to find with other instruments, and it is hoped that one even more simple and useful will be perfected. It is believed, however, that the present instrument is sensitive enough for water works laboratories and will answer the purpose in case nothing more convenient and cheaper is devised.

Turbidity Measurements.—The best procedure for making turbidity measurements is to first test the total turbidity with the instrument shown in Fig. 4. This instrument and the procedure for making the standards and the test is explained in two articles

which have been published already*. Record the results as the total turbidity, for it includes all the suspended matter. If a floc detector as shown in Fig. 5 is available use it for determining the floc turbidity. Subtracting the floc turbidity from the total turbidity should give the fine turbidity. If no floc detector is available fairly good results may be obtained by filtering the water, after the total turbidity determination has been made, through a No. 12 Whatman folded filter paper. The paper should be washed thoroughly by filtering through at least one liter of clear water. It may then be used for filtering several samples of water if only a small quantity of flocculated matter is present. It should not be used after it begins to show signs of clogging. Test the filtrate for turbidity the same as for the total turbidity and record the results as the fine turbidity. The difference between the total turbidity and the fine turbidity should give the approximate floc turbidity.

An arbitrary standard of 0.2 fine turbidity and 0.05 floc turbidity has been set by the writer as that beyond which the water should not exceed. This seems to produce water that is satisfactory in every respect for domestic uses. In the practical operation of filtration plants the coagulation should be increased if the fine turbidity exceeds 0.2 and it may be reduced if the turbidity is less than 0.2. When the floc turbidity exceeds 0.05 the filters should be washed more often, and when it is less than this amount the filters may be allowed to run until the loss of head reaches the maximum. If only the total turbidity is measured, and it exceeds 0.2, there is no way of telling whether it is due to fine turbidity alone, floc turbidity, or a mixture of the two. Table I gives the daily records for a period of several days on two occasions in which the filtered water of a certain plant materially exceeded what it should have been. Twenty days are given. It will be noted that out of the 20 there were 8 days in which the fine turbidity exceeded 0.2 and the coagulant should have been increased and that there were only three days in which the floc turbidity did not exceed 0.05. For some of the days both the coagulant should have been increased and the filters washed more often. There were 6 days in which the fine turbidity was not over 0.1. On these days the total turbidity was high, yet the coagulant could have been reduced. It might be well to state that these records are not typical of average operating conditions for this plant. They were the two worst conditions experienced at the plant. The average results were good.

*Baylis, John R. J. Am. Water Works Assoc., 11: 4, 284, July, 1924. Ind. & Eng. Chem., 18: 3, 311, March, 1926.



LABORATORY FLOC DETECTOR

Fig. 5—Laboratory Floc Detector

Accurate turbidity measurements on the filtered water are of great aid in the efficient operation of any filtration plant, and it is evident that the cause of the turbidity should be known. No one device will answer all purposes though it may result in improved operation. It is true for some waters that there is not much danger of flocculated matter passing the filters, and in these cases there is not much need for the floc detectors, yet they should not be omitted unless several years of careful observations show that they are not needed. Even then they would be worth the cost to detect occasional breaks in the beds.

Service Lines

Useful Information on Installation and Care

By W. C. HAWLEY
Chief Engineer and General Superintendent, Pennsylvania Water Co., Wilkinsburg, Pa.

ONE of the most important things in the installation of service lines is the tapping machine, with which the main is drilled, the hole tapped and the corporation cock screwed into place under pressure; that is without the necessity of shutting off the water pressure by closing gate valves in the main. In choosing be sure to get a machine which has been used by others satisfactorily under similar conditions and one that is not too heavy for easy transportation and handling.

Tapping the Main.—The main should be tapped at an angle of about 45 deg. from the vertical where there is any danger of frost. Where there is no such danger it may be tapped on top and thus provide a means of escape for air which may accumulate in the main.

Many water works men believe that a corporation cock larger than the 1-in. size should not be used and even the 1-in. size is not used by some, where pressures are high. This avoids the danger of splitting the pipe by the wedge action caused by screwing the corporation cock into the main. Where 1½-in. or 2-in. service lines are needed it is better to insert two or more ¾-in. or 1-in. corporation cocks at safe distances from each other and staggered, that is not put in along the same line on the main, thus avoiding the danger of splitting the pipe as explained above. Where two or more corporation cocks are used they can be connected with goose necks to a header attached to the larger pipe.

Service lines should be laid at depths sufficient to protect them from frost. This depth will vary according to kind of soil and the amount and degree of cold weather to be expected and no chances should be taken. Remember the winter of 1917-18.

Laying the Service Line.—A service line should be laid at right angles to the street in which the main is laid and it should not be laid in a sewer trench as any leakage will probably find its way into the sewer instead of going to the surface. The only exception to this rule should be when the trench is in rock and then the sewer trench should be at right angles to the street and not at about 45 deg., as sewers are usually laid, and the water pipe should be placed on a bench on the side of the trench at the proper depth.

The service line to the curb should be laid by competent and experienced men. The consumer's service line should be inspected in open trench to insure its being of proper material and workmanship and at proper depth to make it safe from frost. Our company

has found it advisable to have the consumer's service line laid first and inspected. The company's service line is then laid and the connection at the curb to the consumer's service line made by the water company's employes.

Capacity of Service Line.—The capacity of a service line depends upon the pressure at the main, the length of the service line, its internal diameter and the character and condition of its interior surface. The pressure and the length are known quantities. The character of the interior surface and its future condition are matters determined by judgment and experience, so that the only really unknown quantity is the diameter, and the proper diameter will depend upon the demand made upon the service line by the occupants of the premises supplied through the various fixtures installed for water service. For the ordinary dwelling a demand of about 1 cu. ft. per minute is not unreasonable. As the number of people and fixtures increase the demand will be increased correspondingly. With normal pressures of 60 to 100 lb. and streets of 60 to 80 ft. width and houses at 20 to 30 ft. back from the curb line, a ¾-in. service line in good condition should meet the demand of the ordinary family. We must recognize, however, that with the installation of fixtures requiring water delivered at rates in excess of those which were demanded a few years ago, such as laundry trays with ½-in. spigots, shower baths, etc., we must be prepared to deliver water at rates somewhat in excess of those which were adequate a few years ago.

Methods of Removing Deposits.—With some waters there is a tendency for the deposit of silt or oxides of iron and manganese in the service lines, which in course of a few years may cause noticeable reduction in capacity. If this is likely to occur, it must be taken into consideration in deciding upon the size of service line which is necessary.

Incidentally, there are methods of removing such deposits in lead or other pipes with smooth interior surfaces without the necessity of taking up the service line or going to large expense. The use of a tissue paper plug forced through the service line by a force pump has given good results where the pressure in the main is not too high. The paper soon disintegrates and is not objectionable. Gum drops have been used for the same purpose and one of the best materials is coarse salt. The latter can be used when pressures are high.

Demand for Larger Service Lines.—In recent years there has been a rather general demand for larger service lines and meters as well, due to the introduction of Flushometers. If these fixtures used larger quantities of water it would be easier to convince the average water works man that the water utility should increase its investment in service line and meter for the purpose of giving such service. The fact is, however, that the Flushometer probably reduces somewhat the total amount of water used, and sooner or later it causes water hammer. In some places the demand for larger service lines has been granted, but in most places it has been refused and the satisfactory use of the Flushometers has been made possible by the installation of an air tank connected to the water pipe in the building supplied.

It is difficult to convince a consumer that he should not be given a large service line. He will argue that he wants a connection to the main which will give service on the second or third floor whether water is being drawn in large quantities in the basement or not. He does not appreciate the increase in investment required to give that kind of service nor that the amount of water used will not be materially increased. Explanations to the effect that a large meter is not as sensitive on small rates of flow are not appreciated by him. The most effective argument is in the case of a water utility which has a service charge based upon the size of the service line or the size of the meter. He can understand and appreciate a larger service charge, especially when it does not pay for any water.

The rules of most water utilities provide that there shall be but one service line to each property supplied, except sometimes in the case of large buildings. This is a reasonable rule and has been approved by Public Service Commissions. There is no good reason for the water supply for a building being taken from two or more service lines with two or more meters to be looked after and maintained and two or more accounts to be kept.

Laying Service Lines to Vacant Lots.—The demand that service lines should be laid to vacant lots, etc., before pavement is put down is one which has caused much trouble. Where it has been tried it has been generally unsatisfactory. No one can foretell the size of a building which will be erected on a lot at sometime in the future, nor what will be the demand for service. Wide lots are frequently subdivided into narrower ones so that the service lines which have been put in are too few. The proper location of the service line cannot be foretold and many service lines which have been put in before paving have never been put into use. The Public Service Commission has refused to compel the water company to install service lines before pavement is laid. It is probable that no type of pavement has as yet been put down which cannot, with proper care, be replaced when it is necessary to cut through it to lay a new service line or make repairs. The back-filling of trenches and the replacing of such pavements demand the utmost attention on the part of the water works manager and the work should be done so that it is not a source of reasonable complaint on the part of the municipality.

Back Filling Trenches.—In places where crushed slag can be obtained it is becoming quite customary to use it for back-filling trenches after 10 or 12 in. of clay or earth has been placed and tamped over the pipe. The slag can be wet and tamped into place without danger of further settlement to any extent. Temporary pavement can be put over it and in two or three weeks it is ready for the placing of permament pavement with no danger of further settlement. A better arrangement would be for the municipality to take over the back-filling of all trenches and the replacing of pavements over them for which the water utility would pay a reasonable fee.

Service Line Records.—And one thing more. There should be kept a record of every service line, showing its size, material, length, location, etc. This data should not only be written but there should be a sketch so that it will be possible with the information given to go out onto the street and by making two to four measurements locate the service line accurately. These measurements should at least be from the property line of the intersecting street and from the curb to the tap. There should be two or three check measurements from objects as nearly permanent as possible, such as a fire hydrant, a gate valve box or the corner of the curb or from the corner of a building. Measurements from trees, telephone or electric light poles, etc., are not of much value, as trees are cut down and poles are moved. Even curb lines are changed at times, but there should be enough measurements made so that although one or two of the objects from which they are made are moved, it will still be possible to locate the service line. In these days of permanent pavements it does not make the municipal authorities feel very good and it is expensive to have to dig through the pavement in three or four places to locate a corporation cock when it might have been avoided by the keeping of proper records. Such records should be checked and brought up to date at every opportunity. Curb boxes should be maintained in good condition with the tops at the proper elevations and if service lines have always been put in at right angles to the street the location of the corporation cock can be found at least approximately if the distance of the main from the curb is known. The curb box should be inspected every few years and kept in good condition, ready to operate in case of a leak doing damage in the property or the necessity of shutting off for neglect to pay bills, etc.

Meter Accounting and Reading by the Water Department of Detroit

How Detroit Reads 245,000 Meters

By W. C. BOWEN
Supervisor Assessment Bureau, Department of Water Supply, Detroit, Mich.

THE Assessment Bureau is chiefly concerned with the problem of determining how much water is delivered to each of the department's 245,000 customers through an equal number of service lines, and such other activities as are naturally allied.

Ninety-nine per cent of the service lines are metered, which fact goes a long way towards solving the problems of the bureau. It is, however, no small task to read 245,000 meters at least four times a year and many of them more often. To accomplish this in the most satisfactory manner the following plan was worked out and put into operation two years ago and is proving to be by far the best system that has to date been tried.

City Divided Into 36 Districts.—The city was first divided into three zones, each having approximately the same number of meters within its boundaries, and were named Eastern, Western and Central. Each zone was then divided into twelve districts. Considering the number of meters in service at that time it was necessary to so divide the zones that each district would have about 7,000 meters. Districts were so numbered that the number of the district not only designates the district but also the zones, namely, districts of the Central zone were numbered from 11 to 22, inclusive, Western from 41 to 52, Eastern from 71 to 82. The intervening numbers were left for expansion.

It is now noted that the city has been divided into 36 districts, each of which must be read once every three months, making it axiomatic that one zone or twelve districts must be read every month. As there is but an average of 24 working days to a month it is seen that only two days could be allowed for the reading of each district.

1,685 Route Books.—Districts were then divided into routes, each containing a sufficient number of meters to constitute one day's work. The number of meters in each route vary in accordance with the territory ranging from 120 meters in business and factory centers to 180 in some residential sections. Each route was given a number so that, being given district and route any reading sheet can be immediately located. Reading sheets for each route were then locked into a specially designed binder, upon which was printed the district and route. We have at present 1,685 of such route books. They are filed in a specially designed cabinet in such a manner as to be most readily procured. A card index system, wherein streets are arranged alphabetically and in rotation as to house numbers, serves as a key to the route books.

Readers report each morning to the main office, turn in the books completed the previous day, receive the books assigned them for that day and immediately set out for their route. It is well understood that, barring mishap of some kind, no excuses will be accepted for failure of a reader to complete his route.

Checking by Assessment Clerks.—Following completion of route books they are scanned by assessment clerks, who go over each book, sheet by sheet, checking the readers' computation, considering the probable correctness of each reading, ordering check readings where necessary, writing up "pick up slips" for all meters that were for some reason passed by the reader, reporting meters out of order and new jobs ready for meters, computing and entering construction service charges, estimating consumption (of which more will be said later), as well as various other details that are necessary in order to get the books in shape to turn over to the billing bureau.

As above mentioned, meters that were passed by the readers are caught by the assessment clerks who make out pick-up slips. There readings are obtained the following day by a group of readers known as "pick-up men." Any meter passed by this group or about which additional information is desired is turned over to the night reader, meter reader foreman or chief inspector, as the case may be. From this it is noted that the route books are a long way from being ready to turn over to the billing bureau when turned in by the readers as completed.

Delivery of Bills.—The Assessment Bureau is also responsible for bill delivery. Six men are assigned to this work. All bills prepared one day are delivered the next day. The schedule calls for the bill to be in the customer's hand 15 days after the first call of the reader. Ways and means are now being considered as to how this period can be still further shortened.

Method of Estimating Consumption.—We believe that a special paragraph describing our method of estimating consumption is deserved, for there is no other duty of the assessment clerks that requires that fine degree of good judgment and application of common sense as does estimating the amount of water consumed by a certain customer during a definite period. It is probably needless to say that this method of arriving at a consumption is resorted to only after all other methods have failed, but even at that, unfortunately the necessity often arises. An average of 3,500 accounts are checked each day by the assessment clerks and of this number there is an average of 300 accounts that for some reason no reading could be obtained. The most common reason is the inaccessibility of the meter and next to that the fact that the meter does not indicate true consumption. An estimation in case of the former is not so serious, as a reading will eventually be obtained at which time any error in estimation is corrected; but where the meter is out of order, that's different: there will be no later reading. Our estimates vary from a few hundred feet to a few million feet or as expressed in money from the minimum bill of $1.25 to well over $1,000. There can be no definite rules set up to govern estimates as there are no two cases just alike. Our limited space forbids a detailed treatise on this subject, but sufficeth it to say that all available information, such as a record of past consumptions and a report on present conditions at the premises is gathered together and considered before the estimate is made. Often in case of large consumers a personal call to the premises is made when an opportunity is given the owner or an official of the company to express his opinion as to the probable consumption. We have found the large consumers, particularly large institutions, always ready and willing to co-operate and meet us half way in a matter of this kind.

Construction Service Charge.—Provision has been made for supplying water for building purposes by installing services before there is any possibility of setting a meter and allowing use of the unmetered line until the building is completed and occupied. While this arrangement is a decided accommodation and convenience to the builder and owner, it is just another problem for the assessment bureau, which much determine how much water was used through each service before

the meter was installed. After trying several plans with more or less unsatisfactory results, the plan now in use was decided upon and is working out very satisfactorily. The idea of estimating the consumption or assessing a fixed charge known as the building tax for each new building and varying according to types, was given up and superseded by a monthly flat rate charge known as construction service charge, same to run from the date of service installation to the date of meter installation. This charge is applied only to ¾ in., 1 in. and 1½ in. services, which constitute 95 per cent of the total.

After considering the amount of water actually required for construction of certain type buildings, the average amount wasted, the usual type of building using a ¾ in., 1 in. and 1½ in. service, the rate of $.75 per month for ¾ in. and $1.50 for 1 in. and 1½ in. service was adopted as being sufficient to cover in the aggregate the cost of this service.

Under this plan accounts are opened on the day service is installed and allowed to run until meter is installed and up to the time of the next regular billing period, at which time the number of months of unmetered service is noted and multiplied by the proper monthly rate, which amount is billed as the construction service charge. Considering that there is an average of seventy new accounts opened daily the year around it is readily understood why this plan is popular with the assessment bureau, as each account is handled in precisely the same manner, whereas under the old plan each new account had to be individually considered; not only that, but it establishes a definite date of collection and a definite rate. It removes all opportunity for a customer to complain that he was charged more than his neighbor for like service, or that he obtained his water supply for building purposes from the county ditch.

For the benefit of the customers who dislike this flat rate plan, arrangements have been made to install meter at any time upon request of the owner, provided that proper preparation has been made for its reception.

Service lines over 1½ in. in diameter are used by buildings of such various types and sizes that this plan is not applicable. In all such cases the building tax is arrived at by ascertaining the amount of the various materials used in the building and applying the rate so based as has been adopted by the board. To this is added the regular service charge for the period of unmetered service, the total being the building tax.

Special Readers for High Consumption Meters.—High consumption meters are read monthly by special readers whose duty it is, in addition to reading, to see that they are so functioning as to constantly indicate true consumption. Frequent tests and minor repairs are made on the job. They have so arranged their routes that one of their regular readings will be made at the time of the scheduled billing reading. These readings are turned over to the assessment bureau where they are transferred to the regular reading sheet and the accounts prepared for billing.

As has been before mentioned 99 per cent of the service lines are metered, the other 1 per cent for various reasons are not. These few accounts are carried on assessed rate, the rate being determined in the usual flat rate method of basing it on the number of openings and the purpose for which the water is used.

Special Assessment Record. — The board's desire to furnish water for every legitimate purpose and in the manner most convenient for the consumer has necessitated the keeping of a special assessment record. Every day applications are made for temporary water service, and in those cases where a permanent service installation would not be practical nor the expense justified, the applicant is given permission to use a fire hydrant.

It is the assessment bureau's problem to determine how much water is used for the above mentioned purposes and in what amount each permit holder is to be billed. A clerk, known as special assessment clerk, is assigned to this work. A description of our methods of determining water consumption in such cases would be too lengthy to be included in this paper, as it is obvious that there must be a different method for nearly every case, but as an illustration we will cite that of pavement construction.

At the end of each paving season we obtain from the records of the department of public works the amount of paving done by each contractor. From these records the yardage of concrete is computed. Yardage times known amount of water required per yard plus a certain percentage for wastage equals approximate amount of water consumed.

During the year 1926 $11,810.55 was paid to the department for the use of water from fire hydrants ranging in amounts from $1.00 to $3,537.65.

The assessment bureau receives and investigates all service bill complaints. It is the aim of the bureau to go full length to satisfy each and every customer by check readings, and investigating for cause of high bills. Very few complaints are carried to the adjustment committee of the water board.

The bureau has charge of the addressing machine room consisting of the addressing of water bills, making of addressograph plates, printing of forms and notices used by the department of water supply and allied work.

Acknowledgment.—The foregoing is taken from a descriptive survey of the Detroit Department of Water Supply, issued last fall by the department.

Revenues and Expenditures of Cities

The U. S. Bureau of Census, Department of Commerce has just issued a bulletin giving the financial statistics of cities having a population of over 30,000, the figures being for the year 1927.

Assessed Valuation and Tax Levies.—For the two hundred fifty cities having a population of over 30,000 the assessed valuation of property subject to general property taxes for city purposes amounted to $74,731,205,845, or a per capita of $1,749.47.

The total levies on the property subject to general property taxes in these cities for the governments of the cities, counties, states, school districts, and all other governmental units for all purposes amounted to $2,278,379,544, or an average for each person of $53.34.

Revenues.—The total revenue receipts in 1927 of the 250 cities having a population of over 30,000 were $2,945,511,729, or a per capita of $68.96. This was $713,084,994 more than the total payments of the year, exclusive of payments for permanent improvements, but $378,874,622 less than the total payments, including those for permanent improvements. In only seventy of the cities was there sufficient revenue to meet all payments during the year. The payments in excess of revenue receipts were met from the proceeds of debt obligations.

Governmental-Cost Payments*.—The total cost of government in 1927 of the 250 cities in this class amounted to $3,324,386,351. An analysis of this total shows that the costs for the operation and maintenance of the general departments were $1,750,707,093, a per capita of $40.98, and representing 52.7 per cent of all costs of the 250 cities; operation and maintenance of public service enterprises, such as waterworks, light plants, public markets, and similar enterprises, $162,470,940, a per capita of $3.80, and 4.9 per cent of the total; interest on debt, $319,248,702, a per capita of $7.47, and 9.6 per cent of the total; and for outlays, or permanent improvements of general departments and public service enterprises, $1,091,959,616, and 32.8 per cent of the total cost.

Expenses for Operation and Maintenance of General Departments: 1927

	Total (000 Omitted)	Per Capita
All general departments	$1,750,707	$40.98
General government	148,061	3.47
Protection to person and property	350,341	8.20
Health and sanitation	176,996	4.15
Highways	157,198	3.68
Charities, hospitals, and corrections	106,492	2.49
Education	668,263	15.65
Recreation	60,364	1.41
Miscellaneous	82,992	1.94

*The governmental-cost payments include all payments for the year, whether made from current revenues or from the proceeds of bond issues. The proceeds from the issuance of debt obligations are not considered revenue receipts.

Unusual Conditions Discovered through Pitometer Water Waste Surveys

A Discussion of Particular Interest to the Water Works Superintendent

By H. E. BECKWITH
District Manager, The Pitometer Co., New York, N. Y.

IN the 30 years our company has been conducting water waste surveys improvements in our methods of operation have come as often from the criticism and helpful hints of persons outside our organization as they have from the development of new ideas on our own part. Consequently, in calling to your attention those conditions which we have encountered in our work, I am not prompted by any unholy joy in pointing out the mote in my brother's eye. It is rather by way of returning in small measure the helpful courtesies shown us by the men in the water works field, and with the hope that you may find some helpful hint in the conditions we have found in other plants.

When the Valves Were Closed.—It is, of course, very common for us to find closed valves. Your attention is called to two such instances: In the first of these an entire town of some 20,000 persons was being fed through four 6-in. mains, because a valve on the main 16-in. feed was closed. Moreover, this was the only valve in the entire system found closed, showing that care was taken to check up on the valves. Furthermore, and this is of special importance, it was the only geared valve in the system. When the operating nut on the gear was turned in a clockwise direction, the valve stem was turned counter-clockwise. As the valve stem on this valve closed in the same direction as all other valve stems in the system, it was necessary to turn the operating nut in the direction opposite to that of every other operating nut in order to close the valve. Someone failed to take this into consideration, with the result that the valve had been kept habitually closed.

In the second case, the hydraulic grade line was apparently lower at one point than it was at another point on the same line, ¾-mile further from the source of supply. This was on the system of a small company serving several miles of territory with laterals feeding directly off one long main, or rather it had been one long main originally. For 1½ miles of its length it had later been paralleled with another main. This second main was tied to the original main at no place other than at its ends, and no laterals came off of it. A study was being made for the purpose of reinforcing the system. When the hydraulic gradient for the system, as determined in the field, was plotted on cross-section paper, it was found that midway between the ends of the two parallel mains the hydraulic grade line was lower than at either end. Subsequently, the valve on the reservoir end of the "old" main was found to be closed. All water being used along the mile and a half of parallel mains had to go to the farther end and then feed back toward the reservoir. Opening the closed valve, of course, took the sag out of the grade line and increased pressure below the point where the valve had been closed. The trouble in this case was caused by right and left-hand valves being indiscriminately sprinkled throughout the system. Volumes could be written about the trouble caused by indiscriminate use of both right and left-hand valves in the same system. This is merely another example of the results of this practice.

Why the Supply Main Delivered No Water.—Speaking of hydraulic gradients, there is the case of the city whose officials had believed their system was being fed by two mains from the reservoir. A pitometer test proved, however, that there was no flow through one of these pipes. Further investigation showed that this main at one point actually lay above the water-level of the reservoir. After the line was lowered, its vacation was over and it went to work delivering water to the city.

Accounting for a 50 Per Cent Loss.—Another very interesting case was that of a city which had originally been served by two separate companies. Later, these companies were merged and the distribution system was interconnected. Each of these companies originally secured its water by gravity from a mountain reservoir, the reservoir of one company being 12 ft. higher than that of the other company. Since the complete metering of this system a few years ago the meters through which water was sold had accounted for a little less than 50 per cent of the water shown on the Venturi meters installed at the reservoirs. Our tests showed that during the night, when the use of water in the system dropped low, the water fed out of the higher reservoir into the lower. It is the nature of a Venturi meter to measure in a positive direction the water which goes through it, regardless of the direction of flow. Consequently, the water which fed from the higher to the lower reservoir was measured on each of the two Venturi meters, although as a matter of fact, it was never used in the distribution system at all. When the Venturi meters were originally installed the city was on a flat rate basis, and the waste of water was so large that it is doubtful if the water ever backed up into the lower reservoir. But with the metering of all the services the amount of waste gradually fell off until the condition prevailed of which I have just spoken.

Whenever a water system is fed by gravity from two or more reservoirs on different levels, it is well to grow immediately suspicious of back-feeding when the supply in the lower reservoir holds up better than the supply in the upper one.

Incorrect Meter Reading.—Another very interesting case was that of a small suburban city which purchased water from its larger neighbor by meter. As the city was being paid on its meters for less than half the water entering the distribution system, the water department had accummulated a large deficit. In addition to the conditions usually found by a survey, it was discovered that two 4-in. and two 6-in. meters were being incorrectly read, and that the city was being paid for only 10 per cent of the water going through them. The value of the water which had passed through the meters, but which had never been paid for, was nearly equal to the deficit of the department. An effort was made to collect this money on the grounds that the bills rendered the consumer bore the meter-readings and his acceptance and payment of the bills constituted an acceptance of the correctness of the meter-readings. As the department did not use a step rate, the matter of billing was comparatively simple. It is to be regretted that we cannot advise you as to the outcome of this attempt to collect, as we left the city before any settlements were made. Two of the consumers had, however expressed a willingness to pay; and I understand that the state commission had ruled that any failure on the part of the city to collect the full amount would be equivalent to the granting of preferential rates and would therefore be contrary to law.

This under-reading was caused by the fact that the smallest dial on the meters involved was graduated in units of one hundred, whereas the smallest dial on

all other meters on the system was graduated in units of ten. The meter-reader entirely overlooked the necessity of investigating the meter to determine in what units it was graduated.

How to Prevent Inaccurate Meter Reading.—That this is not the only case of its kind is shown by the fact that another similar condition was recently found. As a remedy for this it is suggested that meter-readers be not permitted to take their previous readings on a meter into the field and so help to carry the error through. It is further suggested that the office clerks be forbidden to change any readings in order to make them conform to previous readings. Wherever a doubt exists as to the accuracy of the reading on a large meter, it would be well to have it checked by the meter company's representative.

In another suburban city, which also purchased its water through a meter, periodically the receipts from the water department would drop below the cost of its water. The trouble in this case lay in a compound meter to a steel mill. The high duty side of this meter was dead; and whenever business was sufficiently good with the steel company to cause a draught of water large enough to throw the flow onto the high duty side of the meter, business was very bad with the water department. Another factory in a different part of the city had been suspected of stealing the water, which is probably the one reason why the real cause of this lost water was not discovered before.

In the same place the larger city had metered two services, and had for years been collecting revenue from them, when, in reality, the services were attached to the mains of the smaller town. Both cities had mains in this one street. In this case, all moneys that had been so collected were turned over to the smaller town.

The Source of the Spring. — In another suburban borough which purchased water by meter, the newspapers stated that the leak discovered by the survey had been running for twenty-five years and had cost the borough in that time a quarter of a million dollars. This is not of particular interest here, except as it lends point to another statement made by the same news article. It seems that, when a large sewer was laid past this leak, it was impossible to handle the water with a pump. It was decided that a spring had been tapped and special foundations were put in to protect the sewer. It should be noted here that the leak was from the open end of an abandoned service of which the borough had no record. In view of the known heavy losses, it is certain that the leak would have been discovered when this sewer was laid, had the water come from the direction of the main and not from the direction of a vacant lot.

It is remarkable how many springs, and swamps even, dry up after leaks on the water system are repaired. And how many people lose their source of valuable medicinal water.

Unauthorized Uses of Water.—Several years ago, when the stock of privately owned water companies was more or less a drug on the market, and few companies had paid dividends in many, many years, we caused considerable consternation on the part of the president of one company where we were working. It developed that a certain manufacturing company in the city was getting about 100,000 gal. of water a day free, through a defective meter. The president of the water company was also president of this factory. It was bad enough, he felt, not to get any dividends on his water company stock, without having the dividends of his factory cut into by increased water bills.

In another case we were called in to locate the cause of a large amount of water escaping from the high pressure system of a middle sized city. By a quirk of fate, it was discovered that 300,000 gal. per day of water were being surreptitiously taken from the system by a plant which was largely the property of the water commissioner. And he was the man who had been most instrumental in securing the commission for us in the first place. Certain it was that this water was being taken without his knowledge.

As a matter of fact, we find it generally true that, where water is being taken in an unauthorized manner, it is done without the knowledge or consent of the higher officials of the companies. It is usually some department head who wants to take a short cut to a good showing for his department.

Low Pump Discharges.—In recent years there has been a rapid increase in the development of electric power, with the result that many water plants have found it economical to substitute electrically driven centrifugal pumps for the old steam plant. Unfortunately, a full realization of the limitations of this type of pumping unit does not seem to have accompanied its installation. In only too many cases the only requirement placed on the pump is that it pump water. No apparent consideration is given to the efficiency with which this work is done. The displacement type of pump allowed so much latitude in operating conditions that many plant operators have not yet come to a full realization that centrifugal pumps operate efficiently only under the design head, and at the design rate of discharge.

No branch of work being done by our firm is more interesting than the efficiency tests on electrically driven centrifugal pumps. In one instance the pumping units were two 2,500,000-gal. pumps, working in parallel to give a combined output of 5,000,000 gal. per day. These pumps were designed to work against a head of 100 lb. The time came when these pumps would not carry the maximum day load. So the output was increased by putting the discharge of these two pumps through a 5,000,000-gal. pump designed to pump against a head of 50 lb. This gave, then, an installation designed to pump 5,000,000 gal. against a head of 150 lb., whereas it was working against a head of only 100 lb. This gave an increased rate of discharge, but at a considerable cost in efficiency. This was not the sole reason why the wire to water efficiency of the installation was under 44 per cent, as several pieces of wood were later taken from the ports of one of the pumps, but it did have a very important bearing on the loss of efficiency. It is of interest to add that, after disconnecting the 50-lb. pump from the discharge of the 2,500,000-gal. pumps, and cleaning these latter out thoroughly, a subsequent test on these two pumps gave an over-all wire to water efficiency in excess of 70 per cent.

In another instance the clear well was of such small size that it was necessary to coordinate the flow from the filters into the clear well with the pumpage out of it. As the low lift pump from the river to the filters had a higher rate of discharge than had the pump from the clear well to the distribution system, this coordination between the two pumps was secured by partially closing a valve on the discharge of the low lift pump. This increased the head at the pump above its design head and induced a slip into it. So much was this increase in head and slip that the power required to pump the reduced flow was much more than would have been required to pump the greater quantity for which it had been designed, had it been operating under design conditions. Throttled down, the pump had an over-all efficiency of approximately 30 per cent. A new low lift installation designed for a discharge equal to that of the high lift pump, thereby eliminating the necessity for throttling, gave on test, an over-all efficiency of approximately 60 per cent.

Another city had been computing its pumpage on a false pump rating, a rating in fact about double the pump's actual capacity. This pump rating was so much in error that, had it been correct, the installation would have had a wire to water efficiency in excess of 100 per cent. And the secret of perpetual motion would at last have been found.

These cases are called to your attention in order to emphasize the necessity for the services of a reputable engineer when this type of installation is contemplated. With the decreasing cost of electricity, this installation is becoming increasingly popular. The efficiency of electrical units should be closedly watched. The greater efficiency being obtained from modern units will often be sufficient to warrant the installation of new equipment.

The speaker recalls one instance

where the replacement of an old installation having an over-all efficiency of 57 per cent with a modern unit having an over-all efficiency of 72 per cent decreased each monthly power bill an amount equal to 5 per cent of the total cost of the new installation.

Then there was the centrifugal pump whose 10-in. discharge line was reduced to 6 in. for a few lengths of pipe. The explanation given for this novel procedure was that the water pressure would be increased after going through the smaller pipe. This reasoning sounds strange to us today, but one of our engineers, delving through the council records of a city where he was working, found a case equally interesting.

When Hydraulic Knowledge Was Limited.—Some sixty years ago when our knowledge of hydraulics was not as extensive as it is today, an engineer had been employed to design a main between the reservoir and the city. This main was partly 20 in. and partly 18 in., fed by a 12 in. from the reservoir. The engineer in charge of the work was the author of the following interesting explanation:

This main line of pipe was enlarged by the direction of the Committee on Water under the light head at the Westerly end, to render the same much more effective as a means of conveying and delivering water at the extreme end of the pipe here in the city. Since the lighter the head, the larger is the required diameter of the pipes necessary to furnish the amount of water conveyed by the small pipe under a much greater increase of head; this change has been one of much utility in increasing the efficiency of this supply main.

Within ten years after the main was put in service, the supply in the city became so deficient that the main was not full at all times. The report of the Water Committee says:

While the discussion was going on about the High Service, the Engineer discovered that the main pipe already laid was wrong end first, and that the advantages of having a small pipe near the reservoir to fill and supply a larger one in the city, were not so great as he at first supposed.

These are only a small part of the interesting conditions found in our 30 years' work.

Acknowledgment.—The foregoing is a paper presented at the last annual meeting of the Central States Section of the American Water Works Association.

Master Regional Plan for Philadelphia.—A purse of $500,000 has been raised by the Regional Planning Federation of Philadelphia to be spent in the next five years in the development of a master regional plan for the city and its environs.

Snow Removal in a City of 25,000

Beloit, Wis., Disposes of Snow Through Storm Sewers

By C. O. RICKSECKER
Superintendent of Streets

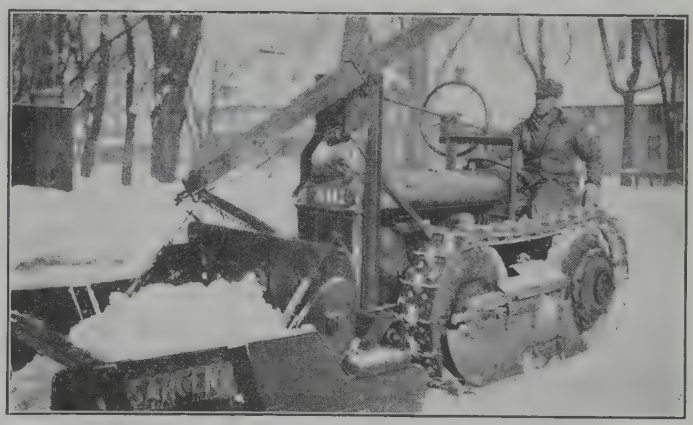
THE present administration of the city of Beliot, Wis., believes that it pays to keep the roadways of the business section free from snow and ice. Accordingly, city officials have carried out a policy of removing accumulated snow as rapidly as possible, and the most efficient methods of disposal have been sought to permit of securing the results desired.

Beloit is a city of about 25,000 population, having about 60 per cent of its roadways paved. The business section is divided by the Rock River, which conveniently allows large storm sewers to be brought under the downtown thoroughfares. A bridge with two trap doors over the river channel is centrally located. Thirty-three-inch manhole covers are placed on storm sewer manholes at favorable locations.

Disposal Through Manholes or Bridge Traps.—If a heavy snow is falling rapidly, it is plowed towards the curb to keep the roadway open until the storm is over. A motor patrol is then put on the streets to bring the snow back into the roadway in windrows not too large to handle. A truck or tractor then draws a snow scoop into the windrow of snow, where the scoop is loaded by one man. The loaded scoop is drawn to the nearest manhole or bridge trap and dumped as it is being drawn over the opening. The winter of 1928-29 was the first that motor power was used to draw the snow scoops.

If a snow is not falling too rapidly, the snow is plowed into windrows and moved away without first plowing towards the curb. A light snow may be moved from the curb into the roadway during the early morning hours, permitting automobiles to park normally while the snow removal is carried on during the day.

In disposing of snow through the storm sewer manhole, it is necessary to use a stream of water to carry the snow away. This is done by threading a fire hose through the storm water intake lateral and attaching it to a fire hydrant. This operation can be simplified by laying a small sewer pipe from the fire hydrant into the manhole at a time when new pavement is being laid; then only a short length of hose is needed to convey the water from the hydrant to the intake at the near end of the small pipe.



Motorized Equipment Keeps 80 Miles of Streets in Beloit, Wis., Open for Traffic During the Winter Months

Equipment.—One or two motor-powered road graders are used for keeping the snow in windrows. From four to six snow scoops drawn by one-ton trucks or Fordson tractors are sufficient if the haul is limited to two city blocks. The snow scoop used is the old-fashioned wooden scraper that has been in use for many years by ice harvesters—usually drawn by teams of horses. We are finding these wooden scoops rather light to be drawn by motor power and feel that there is room for improvement in this equipment.

In the residental sections, Beloit uses motor trucks fitted with mouldboard type snow plows. At this time the city owns two 5-ton street flushers that are snow-plow equipped in winter. An arrangement is made with a local contractor whereby the city furnishes the snow plows to equip his two 5-ton Mack trucks, thus making available four snow plows that are kept on the move during a storm to keep about 80 miles of streets open for traffic.

Adjustable Vanes on Turbine Runners.—Turbine runners at the Chippewa Falls plant of the Northern States Power Company in Wisconsin are equipped with adjustable vanes, the angle of which can be adapted to meet varying water conditions.

Should Engineers Study the "Humanities"?

At the recent dedication of Dabney Hall, "the hall of humanities," at the California Institute of Technology, Dr. William B. Munroe said: "There is no good reason why engineers should be more limited in their intellectual versatility or in the range of their human interests than men in any other profession.

"These (humanity) courses cover the field of English and foreign literature, history, philosophy and social ethics, economics and government. No man can master science if he sets out to master science only. The history of human achievement has but a single page."

While we are believers in the thorough teaching of English and economics in all engineering colleges, we question the inclusion of the other subjects mentioned by Dr. Munroe, and we question even more seriously his whole attitude toward science.

Philosophy? What is it all about? The editor has studied at least three dozen books on the subject, and with the exception of those by Herbert Spencer, they constitute, for the most part, a very peculiar melange. In a recent editorial article entitled "Is Philosophy a Branch of Science?" we expressed the opinion that philosophy is a mixture of ultra-science (and therefore no science), metaphysics, morality and religion. We used Durant's "Story of Philosophy," and his definition, or rather description, of philosophy, to illustrate our meaning. He virtually admits the impossibility of defining philosophy, and by that very admission indicates the confusion that pervades that alleged realm of knowledge. Durant says: "Science gives us knowledge, but only philosophy can give us wisdom." This sounds erudite enough, but it is marrow of the very bone of nonsense.

The typical professional "philosopher" is a pathetic creature. He often starts by attempting to fathom the unfathomable. Failing, he still has the temerity to say that science lacks wisdom. We have been unable to find a single great discovery of any "philosopher" that has stood the test of time. Of course, many a truth has been uttered by "philosophers," but they were old truths and usually among the most obvious. Spencer came nearer to discovery of a great truth than any of them. But Spencer's philosophy is primarily a broad treatment of one scientific principle which he did not discover, namely, evolution.

Of all the subjects classed among the "humanities," history teaches the least, if you read it as it is taught. History falls even below philosophy in utility, for philosophy may at least set you thinking.

A teacher of history once asked an engineer whether he would not be ashamed not to know the main events of world history. The engineer replied by asking the teacher what causes typhoid fever; and received an admission of ignorance. Then the engineer asked: Which is most worth knowing; the campaigns of Caesar, or how to eliminate typhoid fever?

Typhoid at that time was one of our greatest scourges. Now it has practically vanished in America. Nothing but ignorance has so long delayed its banishment as a disease, but that was a kind of ignorance of which the typical teacher of history was not ashamed. He prided himself on knowing the chronology of kingly events and wars, but he took no pride in knowing how to reduce the death rate in his own town.

Still, it may be argued that when an engineer associates with "cultured" men, he must feel beneath their level if he can not talk about belles-lettres, history and the like. Any such argument shows that the proponent of "the humanities" little understands the culture of science. Was ever a true scientist abashed in making a confession of ignorance? Quite the contrary, for he knows that the all that any man knows is but the filmsiest gossamer beside the vast bulk of the unknown.

Men learn things, (1) for utility, (2) for the mere pleasure of learning, and (3) to secure the admiration that the learned are supposed to inspire; often the last named motive ranks highest. To be able to talk a learned jargon about art, about literature, about the Rome that was before her fall—such is the object of many a man, or at least it used to be a very common object a generation or two ago, when, as Spencer said: "Men dress their children's minds as they dress their bodies, in the prevailing fashion."

William Allen White, one of the speakers at the dedication of Dabney Hall, spoke of the advantage that "Cal. Tech." enjoys by reason of its proximity to "the store of research material at the Huntington library." That "store of research material" is mythical, we believe, in so far as utility is concerned; for it consists mainly of early editions and manuscripts of works that have no great value save that that springs from rarity. Like an indefatigable collector of postage stamps, the late Henry Huntington gathered into this library an amazing mass of literary junk. Grant that many an idle eye may gleam with passing interest over a manuscript poem of Burns or of Poe, and that many a tongue will tell how its possessor saw the first Guttenberg Bible in the Huntington library. There is just as much true worth, and not a tittle more, in such displays as there is in any other collection of antiques that give a thrill to the beholder. We do not deny the desirability of such thrills. We have often enjoyed wandering through such exhibits, and have gladly paid much money to reach them. The point we now wish to make is that the Huntington Library is infinitely less needed by the students and the teachers who work so near its portals than is a great scientific library, comparable, say, with the John Crerar Library of Chicago. The present library of "Cal. Tech." is almost an Eliot 5-ft. bookshelf compared with such a library as such a technical college should have.

Huntington followed his hobby of collecting objects of art and literature, and he poured millions into it. Yet within a rifle-shot and unobserved, there was springing up an institution of scientific culture destined

to make all his collections look as insignificant as the store of nuts gathered by a squirrel.

Huntington apparently had no conception of science, of its beauty and its power, of its culture and its grace, of its research devotees whose imagination outsoars that of the poets.

Einstein working in a garret, locked away from intrusion behind his iron door, was ten years dreaming a greater dream than can be found in all the tomes and manuscripts of the Huntington Library. But it will take more than a generation yet, we fear, before many of our men of great wealth will endow libraries for the use of the scientific dreamers who make their dreams come true. Theirs are the dreams that have lifted humanity above the level of a bestial struggle for existence; for upon an understanding of nature and her laws rests all of engineering and all of that great branch of engineering called invention.

Whenever an advocate of "the humanities" insists that engineering colleges should teach all the so-called "humanities," we rise to demur. With much better array of evidence might we argue that the sciences be given precedence in the courses that lead to an A. B. degree. But the truth is that it is futile to try to be jack-of-all-trades. After graduation many an engineer has beguiled his leisure hours reading history and literature of all sorts, and has puckered his brows over philosophies. Perhaps it has taken the typical engineer many a perplexed moon before it began to dawn upon him that his inability to see to the bottom of these philosophic wells lies not in the profundity of the depth into which he peers, but in the roiled and muddy water with which these wells are filled. If so, that type of reading is ill suited for an undergraduate, be he scientific or be he classical.

After all, a truly cultural course of study is one that trains a youth to become a systematic searcher for information and a good analyst of the significance of facts. When this is made the aim of formal education, less will be heard as to which particular class of facts should be studied. Even history might yield a splendid training in science if taught as research science is taught.

"The Padre of the Rains"

In a quiet little California town; and within the still more quiet confines of the walls of a Catholic university, lives a man whose research work is destined to rank with that of a brother Jesuit, long dead yet but recently become famous. The living man is Father Jerome S. Ricard, "the padre of the rains." The dead man is Gregor Mendel, great discoverer of the law of heredity that bears his name.

A few months ago the editor had the pleasure of interviewing Father Ricard in Santa Clara, and of hearing from his lips an account of his methods of weather forecasting. Since his methods have been described in this magazine, they need not be repeated now further than to say that Father Ricard bases his predictions upon the barometric effects of sunspots. At the first of each month he publishes his predictions for the following 30 days, covering only the weather of the Pacific Coast region.

Each sunspot in the sun's northern hemisphere tends to produce air-whirls on the earth, and if the spot is sufficiently powerful the resulting air-whirls develop into cyclonic storms. Solar rotation brings the same spot around every 27.28 days, as long as the spot "lives," and it is this fact that enables Father Ricard to predict the arrival of barometric "lows" on the Pacific Coast with such accuracy. Whether a rain storm will result from a "low," and exactly what the track of the storm will be, are matters not so certainly predictable; but from interviews with several persons who have kept records of the predictions and the results, it was found that Father Ricard's forecasts have been remarkably correct. Father Ricard said: "Sunspots do for the weather what the moon does for the tides and do it more visibly and more accurately."

Scientists have been so skeptical of the effect of sunspots on weather that they have seldom investigated thoroughly the evidence of that cause-effect relation. And where investigation has been made, it has usually resulted in doubt, because of the seeming complexity of the whole matter. But complexity is often more apparent than real, as the history of science repeatedly shows. Let even one important fact be unknown, and lack of knowledge of that fact may so obscure the entire phenomenon as to give an appearance of great complexity. One of the facts that has been insufficiently attended to, even when it was known (which was seldom), is the fact that sunspots in the sun's northern hemisphere produce exactly the opposite effect on our atmosphere that is produced by spots in the sun's southern hemisphere. Also there should be considered the fact that at about the middle of every 11.2-year sunspot cycle, the new sunspots have a rotation the reverse of that of the old sunspots, and consequently a changed magnetic polarity. In addition to these differences and changes, there is another factor that has received scant attention, namely, the periodic shifting of the latitude of storm tracks. The editor has found that there are 12 giant air whirl-belts, three of which have centers on the arctic circle; and that the cyclonic storms that come out of the north start in these whirl-belts, and travel in parabolic paths southeastwardly. When these giant whirl-belts expand, as they do when sunspots grow more numerous, the cyclonic storms originate in lower latitudes; but, tending to offset that, is the fact that the parabolic path flattens so that the storm center hugs closer to the giant whirl-belt. This usually causes a northward migration of the storm belts, a fact that had been previously discovered, but not explained, by Kullmer.

In one sense the whole problem of storms is complex; in another sense it is not. There are, it is true, several forces to be considered, and that gives it such complexity as it has. But, there is, the editor believes, only one kind of force, namely, electricity, that produces the major effects; and that fact gives to the weather problem a degree of simplicity not hitherto recognized. At any rate, this electrical "key" has already unlocked several doors of meteorological mystery and has made simple what before seemed complex.

In honor of Father Ricard's achievements, the Father Ricard Memorial Observatory has just been built at the University of Santa Clara, where he has taught astronomy and mathematics for many years. The observatory has a 60-in. reflecting telescope. Equipped with this new engine of research, greater knowledge of the relation of sunspots to weather will doubtless be made by "the padre of the rains" and his assistants. But we venture to say that the greatest engine of research in that observatory will continue to be the brain of the man to whom the observatory has been dedicated.

H. P. Gillette

New Books

"Memoirs and Addresses of Two Decades," by J. A. L. Waddell, Consulting Engineer. First edition, 1174 pages, 6 in. by 9 in., hard cover, cloth binding; Mack Printing Company, Easton, Pa., publishers. Edited by Frank W. Skinner, Consulting Engineer. Price, $5.00.

The material in this book is divided into eleven groups as follows:

1—The Engineer Profession, 2—Ethics of Engineering, 3—Technical Education, 4—Engineering Literature, 5—Alloy Steels for Bridge Construction, 6—Economics, 7—Bridge Construction in General, 8—Contracts, 9—Railroad Subjects, 10—Matters Chinese, 11—Miscellaneous Topics.

The great variety of subjects covered by Dr. Waddell during the last 22 years precludes any possibility of confining the material to one subject. It thus becomes necessary to classify his writings in a general way.

It is an outstanding characteristic of Dr. Waddell's professional work to reduce his thoughts to writing after he has completed some particular investigation or project. It is indelibly written upon his mind that transmission of knowledge, ideas and intelligence is one of the greatest forces promoting the advancement not only of our profession, but of the civilized world in general. He, therefore, responded to an irresistible inner urge that took the aspect of a duty, throughout his professional career to open his thoughts and results to the glare of public scrutiny and searching professional sifting.

This book is a compilation of the results of that urge. It should be very suggestive and helpful to all engineers who expect to design or construct important work. The civil engineer in general practice will find in the different pages presented here a broad and practical system; a code of high professional standards; a guide to fundamental technical education; and the epitome of bridge-design essentials which is today the highest standard for advanced construction and practical economics, and which furnishes data for the rational tests, estimates, and comparisons of different important designs.

"The Profession of Engineering," edited by D. C. Jackson, Jr., S. M., Professor of Mechanical and Electrical Engineering, University of Louisville, and W. P. Jones, Ph. D., Assistant Professor of English, University of Louisville. First edition, 124 pages, 5 in. by 7½ in., flexible binding; John Wiley & Sons, Inc., New York, publishers. Price, $1.50.

The articles in this volume, though written by several different men, were selected and arranged to form a unified whole. They give a broad, non-technical, yet detailed conception of the profession of engineering. The following articles are included: The Engineer and His Education, Success in the Engineering Profession, Civil Engineering, Mechanical Engineering, Mining Engineering, Electrical Engineering, The Electrical Engineer, The Chemical Engineer, The Engineer's Contribution to Modern Life.

"Sewerage and Sewage Treatment," by Harold E. Babbitt, M. S., Professor of Sanitary Engineering, University of Illinois, Member American Society of Civil Engineers. Third edition, 545 pages, 6 in. by 9 in., hard cover, cloth binding; John Wiley and Sons, Inc., New York City, publishers. Price, $5.00.

The continued advance through which the art of sewage treatment is progressing made necessary the revision and enlargement of this book. New additions to this text discuss information on the mechanical aeration of activated sludge, on gas collection from sludge digestion tanks, and on separate sludge digestion. In the first part of the book minor revisions have included simplification of methods of computation as in the design of an inverted siphon; correction of numerical solution of illustrative problems; and bring other information up to date.

The book is profusely illustrated and doubtful points clarified by picture or table. It is written more for the purpose of explaining fundamentals than of comparing various methods. The quotation of expert opinions which may be in controversy or the citation of examples of different methods of accomplishing the same thing has been avoided when possible in order to simplify explanations and to avoid confusing the beginner.

"Suspension Bridges," by D. B. Steinman, A. M. C. E., Ph. D., Consulting Engineer, etc. Second edition, 299 pages, 5¾ in. by 9 in., hard cover, cloth binding. John Wiley and Sons, Inc., New York, publishers. Price, $5.00 net.

During the past few years there have been new developments in the art of suspension bridge design and erection. Among the portions of this book that have been rewritten or amplified are those bearing on the topics of wire cables vs. eye-bars, rocker towers, anchorage design, materials used in suspension bridges, economics and limiting proportions, comments on the deflection theory, formulas for temperature stresses, multiple span bridges, proportioning cable bands, calculation of cable diameter, and time records of erection.

Appendix D, on the deflection theory, is perhaps the most important contribution to this new edition.

Appendix E presents an interesting chronological table of suspension bridges.

"The New Technique of Uncovering Security Bargains," by John Durand. First edition, 203 pages, 5 in. by 7¼ in., flexible binding. The Ticker Publishing Co., New York City, publishers.

This volume is intended to meet the requirements of month-to-month investors, where methods of operation occupy a middle ground between deductions from the technical position to which week-to-week traders look for guidance, and studies of values of fundamentals which are the chief reliance of year-to-year investors. The Group Ratio Curve, a tool developed for this purpose, is explained in this volume.

"Sewerage," by A. Prescott Folwell, Sc. D., Member American Society of Civil Engineers, Past President American Society for Municipal Improvements, Editor of Public Works. Tenth edition, rewritten and reset, 399 pages, 6 in. by 9 in., hard cover, cloth binding; John Wiley and Sons, Inc., New York, publishers. Price, $4.50 net.

Research and experiment, statistical analyses with records and operating experience, investigation and new equipment are some of the causes producing improvements and changes in not only the sewerage field but in all fields. This book has been rewritten to cover improvements and changes in the methods of handling sewerage. Progress in methods of sewerage disposal are largely responsible for the production of this book.

As in older editions, Part I concerns sewerage systems and Part II deals with sewage disposal. Beginnings have been made of thorough scientific studies of the biological, chemical, and physical phases of sewage treatment, with special attention to sludge digestion. A number of activated sludge plants have been built. More definite knowledge has been acquired concerning the effects of dilution and the principles involved therein. Inventions of machinery and equipment for treatment plants have come into extensive use. These are the primary causes for this revision.

The book is quite well illustrated.

"Mathematical Tables and Formulas," by Percy F. Smith, Ph. D. and William R. Longley, Ph. D., professors of mathematics in Yale University. First edition, 66 pages, 5¼ in. by 7¾ in., flexible binding; John Wiley and Sons, Inc., New York, publishers. Price, $1.60.

This collection of tables and formulas can be used handily for solving numerical problems of mathematical nature. They are only as accurate as the authors deemed commensurate with that required for practical work. Four figure accuracy was considered usually sufficient. The book should prove of some assistance to students in connection with college courses in trigonometry, analytic geometry, calculus, and mechanics.

"American Sewerage Practice, Volume 1, Design of Sewers," by Leonard Metcalf and Harrison P. Eddy, consulting engineers, Boston, Mass. Second edition, 759 pages, 6 in. by 9 in., hard cover, cloth binding; McGraw-Hill Book Co., Inc., New York, publishers. Price, $7.00.

This volume is primarily a reference book. It is the first of a series of three books by the same authors. American practice in sewer design has attained a certain degree of uniformity and considerable advance has been made in the methods of application of principles in recent years.

Table of contents:

The Lessons Taught by Early Sewerage Works; The General Arrangement of Sewerage Systems; Hydraulics—Flow of Water and Sewage; Velocities and Grades; Measurement of Flowing Water; Quantity of Sewage; Separate Sewers; Precipitation; Storm Water Runoff; Storm Drains and Combined Sewers; Gaging Storm Water Flow in Sewers; Sewer Pipe; Masonry Sewers; Loads on Sewers; The Analysis of Stresses in Sewer Sections; Inlets, Catch Basins and Manholes; Junctions, Siphons, Bridges, and Flushing Devices; Regulators, Overflows, Outlets, Tide Gates, and Ventilation; Pumps and Pumping Stations.

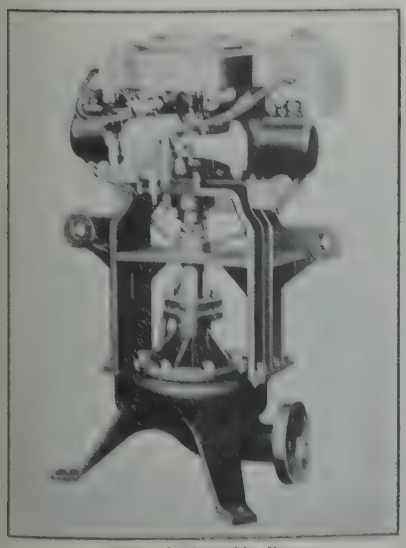
Evinrude Announces New Twin Centrifugal Pump

The new Evinrude pump, incorporating the features of portability, low cost operation, and large capacity, fills a definite need for contractors confronted with the problem of moving excess water from ditches and trenches, supplying pavers and mixers with water, and other everyday jobs. In commercial water transportation, this pump becomes very effective when awkward quarters, too small to handle a large diaphragm or bilge pump, often present a problem of excess water disposal. Dredging companies and barge lines are finding that the Evinrude centrifugal pump is a solution to their problem, for the outfit is portable and requires little space. When the Evinrude centrifugal is used, it is not necessary to start the motor merely to remove a small quantity of water.

This new improved centrifugal is powered by the Evinrude 6-hp. "Fleetwin" motor, a modern twin engine. Manufacturing precision is used in machining, and by carefully weighing and balancing all moving parts, a power plant which is practically vibrationless has been achieved. At the same time, the new pump has been decreased in weight to slightly over 100 lb., making the outfit truly portable and vastly increasing its field of usefulness.

Notwithstanding the fact that the pump is no larger than a small keg of nails, it is capable of pumping 15,000 gal. of water an hour and reaches a head of 50 ft. with ease, the manufacturer claims. The operating cost is negligible, not exceeding 15 ct. per hour, or 1 ct. per 1,000 gal., they state.

The pump itself has but one moving part, the bronze impeller, directly splined to the alloy steel shaft. When revolved, the flukes or vanes of the impeller throw the water outward with a great force and cause it to flow through the discharge pipe. The motor is fitted with the Evinrude magneto of the built-in flywheel type. The flywheel itself acts as an umbrella-like protection over the magneto, shielding it from rain, spray and dirt. Waterproof cables connect to the spark plugs. The Evinrude carburetor brings the advantage of automobile carburetion; a float-feed carburetor which works in any position. With capacity more than doubled over last year, and with the weight decreased 10 per cent, and over all size 11 per cent, the new Evinrude twin-cylinder vibrationless centrifugal pump makes a noteworthy addition to the portable pump field.



Evinrude Portable Pump

Long Handled Meter Key

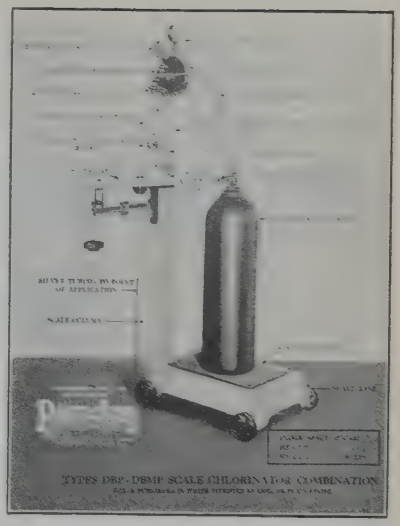
The H. W. Clark Company of Mattoon, Ill., have placed on the market a long handled key for operating their meter boxes. The box has been in production only a short time. It is 16 in. in diameter and 16 in. deep, with a full 12-in. lid opening. The lid is equipped with a rustproof lock, which is operated by the long handled key. A lug on the side of the key may be used to flip back the lid of the meter. The end is provided with a chisel point for scraping.

New Meter Box and Key

A New Combination Chlorinating Scales

The Paradon Manufacturing Co., Arlington, N. J., announces a combination chlorinator-platform scales, known as Model DRP chlorinating scales.

The complete chlorinator is directly mounted on a standard platform scales. The unit is designed so that all parts of the combined chlorinator-scales are interchangeable with the parts of the regular chlorinator without the scale mounting so that existing chlorinator installations may readily be converted to the new chlorinating scale type.



Paradon Scale Chlorinator Combination

The use of a platform scales in connection with a chlorinating installation has practically become standard practice among engineers and sanitarians.

Advantages claimed for the new chlorinating scales are that it saves considerable floor space, makes a neat and more attractive installation than where scales and chlorinator are separate, and that it insures the scales always being available for use with the chlorinator, and not for other uses about the plant.

The cost of the new chlorinating scales, using a standard platform scales, is no more than the cost of the chlorinator and scales separate.

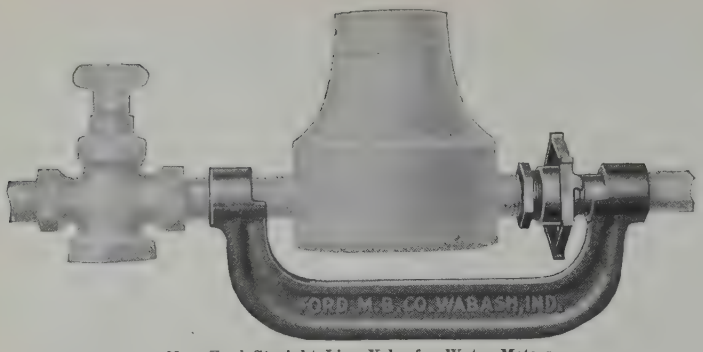
The combination is adaptable to all standard Paradon chlorinators—both solution feed and direct feed types—and for any chlorine capacity.

For further information write to Mr. R. V. Donnelly, Paradon Manufacturing Co., Arlington, N. J.

New Meter Box Yoke Developed

The Ford Meter Box Co., Wabash, Ind., has recently developed a new type of meter box yoke. They have called this new yoke the Straight Line yoke. It is intended primarily for water meter installations where the pipe and meter are set in a straight line through the meter box. Such settings are standard practice in the south and west, where the climate is mild and surface lines shallow. It is also well adapted for basement installations.

A water meter set in such a line with



New Ford Straight Line Yoke for Water Meters

ordinary couplings is very difficult in removal and replacement, as the gasket space is nearly always wrong, and the coupling nuts can hardly stretch the pipe to pull the coupling barrel tight against the meter gasket.

The Ford Straight Line yoke simply provides a strong spacer piece, or yoke, which becomes part of the straight run of pipe, and also provides an expansion connection which screws onto the meter and then expands outward against the gaskets in the yoke saddles to make tight joints. To remove the meter, the connection is contracted and the meter lifted out. The pipes never move and the spacing and alignment are permanently fixed.

The Straight Line yoke costs but little more than the couplings and fittings it replaces, and it gives many advantages. It is made with or without a union for old or new services, and for ⅝-in., ¾-in. and 1-in. meters.

More details may be obtained from Mr. John L. Ford, Ford Meter Box Co., Wabash, Ind.

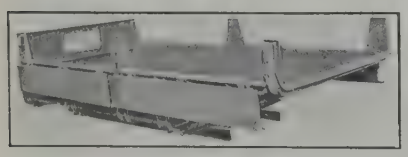
New Garbage Hauling Truck Body

The Wood Hydraulic Hoist & Body Company recently produced new special dump bodies for garbage collection to be used by the city of New York.

The type W-34 special garbage body has sliding steel covers—in four sections, with manually-operated tailgate. It is constructed of high carbon, blue annealed sheet steel—hot riveted and electrically welded for water tightness. Rear end is tapered 20 deg. to allow contents to flow freely when dumping.

The type W-36 is similar to the type W-34, except that it has hinged extension sideboards with patent tailgate which hinges underneath body when dumping, but no steel covers. Tarpaulin covers may be used.

Further information about these garbage bodies may be obtained from the manufacturer.



W-36 Body—Tailgate Hinged Underneath Body and Sides Hinged Downward for Easy Loading

Koehring Pull Shovel Announced

The Koehring heavy duty pull shovel is the latest unit added to the line of excavating equipment manufactured by the Koehring Co., Milwaukee, Wis.

The outstanding features are (1) the shock absorbing principle in the boom base and in the dipper stick and (2) a specially designed jib frame providing a greatly increased working range and flexibility of operation.

The boom shock absorber is identical with that used on the Koehring shovel and in the same manner takes the twisting strains out of the boom and cushions the dipper when trimming the sides of a sewer trench.

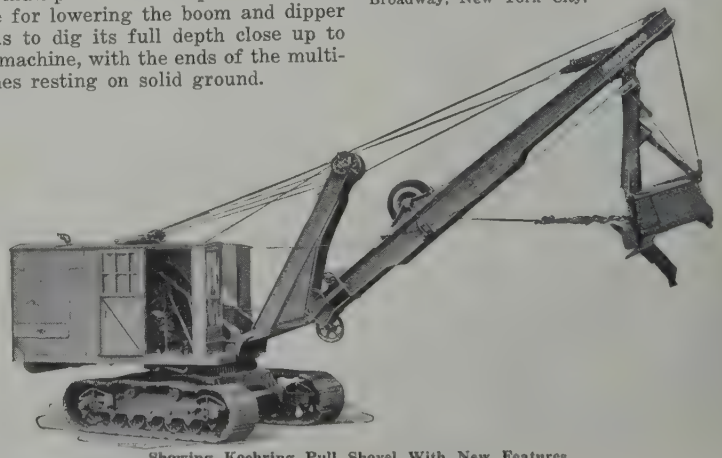
The dipper stick unit adds power to the digging effort by producing a gnawing action in hard, tough digging through the action of the powerful shock absorbing spring upon the dipper.

Instead of being hinged to the turntable casting, the boom is hinged to a separate casting which forms the base of the jib frame. The hinge point on all machines is 6 in. beyond the end of the multiplanes. This provides clearance for lowering the boom and dipper so as to dig its full depth close up to the machine, with the ends of the multiplanes resting on solid ground.

This hinge point can be raised to a working position from 1 ft. 9 in. to 2 ft. above the turntable hinge pin sockets, giving a high dumping clearance. Or, the hinge point may be lowered below the level of the turntable sockets to provide a maximum digging depth.

This construction of the jib frame gives the Koehring flexibility and variation of working range in all operations.

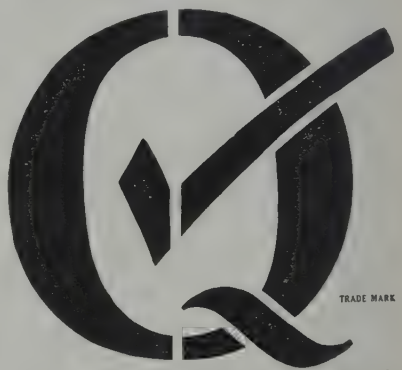
The Koehring pull shovel is built in two sizes, equipped with ⅞ and 1¼ cu. yd. dippers. Digging depths range from 17 ft. to 24 ft.



Showing Koehring Pull Shovel With New Features

Q-Check Distinctive Trade Mark

The symbol shown in the accompanying figure has been adopted as the trade mark of the Cast Iron Pipe Research Association. Cast iron pipe which has benefited through improvements which scientific research has introduced, can hereafter be identified by this symbol. It will appear on cast iron pipe made by the following pipe founders:



The Cast Iron Pipe Research Association's Trade Mark

American Cast Iron Pipe Co., Birmingham, Ala.; James B. Clow & Sons, 219 N. Talman Ave., Chicago, Ill.; Donaldson Iron Company, Emaus, Pa.; Glamorgan Pipe & Foundry Co., Lynchburg, Va.; Lynchburg Foundry Company, Lynchburg, Va.; National Cast Iron Pipe Company, Birmingham, Ala.; United States Cast Iron Pipe & Foundry Company, Burlington, N. J.; Warren Foundry and Pipe Company, 11 Broadway, New York City.

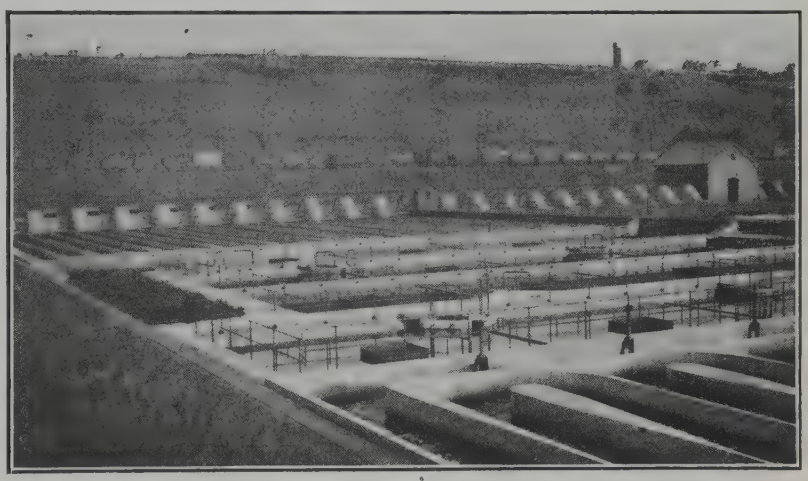
Activation of Sludge By Mechanical Aeration

Development of Mechanical Aeration, Application to Activated Sludge Plant, Described

By W. DEWITT VOSBURY and PHILIP B. STREANDER

THOROUGH aeration and agitation of sewage under treatment are fundamental requirements of the activated sludge process. With the exception of certain plants in England and a limited few in this country, compressed air always has been used to accomplish the purpose. However, there is now a growing tendency among engineers and others to consider the use of purely mechanical devices as distinguished from compressed air to produce the aeration and agitation required. It is the purpose of this paper, therefore, to discuss certain types of mechanical agitators which eventually may become of more or less common use.

However, to understand how mechanical agitation operates to produce the desired results, some knowledge of the activated sludge process is first necessary. A brief description of the underlying principles of this process will therefore be given.



General View of Present Sheffield, England, Plant. Haworth Paddles are Used

Activated Sludge Process.—The activated sludge process has been defined by the Sewerage and Sewage Disposal Committee of the Sanitary Section of the American Public Health Association as one which "consists in the agitation of a mixture of sewage with about 15 per cent or more of its volume of bacterially active liquid sludge in the presence of ample atmospheric oxygen; the agitation to continue for a sufficient period of time to at least accumulate a large proportion of the colloidal substances, followed by sedimentation adequate for the subsidence of the sludge flocculi; the activated sludge having been previously produced by aeration of successive portions of sewage and maintained in its active condition by adequate aeration by itself or in contact with sewage."

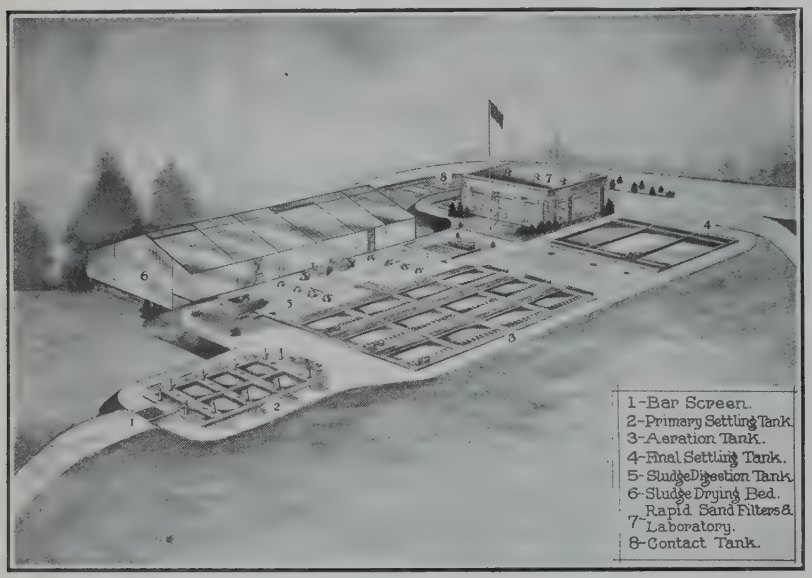
Birmingham, England, Plant, with Hartley Paddles

This definition, translated into terms of at least one type of working plant of moderate size and recent design, implies that ways and means must be provided for: first, elimination of grit, if any is present; second, separation of the coarse solids from the incoming sewage; third, aeration and agitation of the partly clarified sewage in the presence of sludge which has been previously activated; fourth, sedimentation of the aerated sewage; and fifth, disposal by digestion or otherwise of the coarse solids which were first taken from the incoming sewage, together with the surplus of activated sludge not needed for mixing with the sewage while it is being agitated and aerated.

In the operation of a plant of the type just outlined the raw sewage is first passed either through a fine screen or a pre-sedimentation tank, for the purpose of removing as much of the coarser solids as possible. It then enters the aeration tank, where it is mixed with from 10 to 25 per cent by volume of previously activated sludge and then agitated for a period of approximately 6 hours. The resultant mixture of sewage and sludge is then conducted to the final settling tank, where the floc which has been formed is removed by sedimentation and the clear liquid passed from the plant if the degree of

purification so far provided has been sufficient.

A part of the floc or activated sludge deposited in the final settling tank is returned to the aeration tank, where it is again brought into contact with the sewage which is being aerated. In continuous flow plants the cycle of mixing of activated sludge with fresh sewage, aerating and agitating the mixture, settling out the floc and returning a portion of it to the aeration tank is repeated over and over again.



Perspective Drawing of the Activated Sludge Plant Described in the Text. Capacity 600,000 Gal. Per Day; Designed for a Population of 6,000

The process which has thus been briefly outlined is one which is biochemical in nature. It is also similar to that which takes place in a plant where sprinkling filters are used. In the latter the sewage is brought into close contact with growths of oxidizing bacteria which form the bacterial slime on the surface filter media. In the activated sludge process, particles of sludge of similar composition are circulated through the sewage under treatment. Agitation is used to circulate and mix the fresh sewage with the activated sludge. Air is also required to furnish the atmospheric oxygen necessary to promote the growth of the oxidating bacteria. It will be seen, therefore, that both aeration and agitation are fundamentally necessary as a part of the process.

Use of Compressed Air.—In the past, compressed air has been most frequently used for the purpose, since when properly introduced into the liquid it will both agitate it and at the same time supply the oxygen required for aeration. Air is usually introduced into the tank through porous plates in the bottom. In some plants the plates are evenly distributed throughout the area to be aerated. In others the plates are arranged in rows at equal intervals crosswise of the tank so as to form air baffles consisting of curtains of ascending bubbles, through which the sewage must pass. Of late, there has been an increasing tendency to introduce the compressed air through plates located in rows at one side of the bottom of the tank. When this is done in rectangular tanks with proper longitudinal baffling the force exerted by the ascending air along only one side of the tank imparts a rotary motion to the sewage. This results in the sewage traveling in a spiral path from one end of the tank to the other, and the maintenance of a velocity sufficient to prevent settlement of sludge.

Like every other process, the use of compressed air is attended by certain disadvantages. Only a small portion, or about 7 per cent, of the air which is blown through sewage is used for oxidization. The remainder, or 93 per cent, serves only to produce agitation. To use air for this purpose is expensive, in view of low efficiency, relatively high cost of plant distribution system and the losses due to friction in the pipes and diffusers. In addition, the greatest care must be taken to prevent the clogging of the fine pores of the diffuser plates with atmospheric dust, oil from the compressors or rust from the air pipes. It likewise might be added that it cannot be considered desirable to have the essential parts of a plant always submerged in liquid and not easily accessible or usable when in operation.

Experiments in Mechanical Aeration.—In 1905, Adeney of England performed certain experiments which proved that while the surface of de-aerated water remained smooth, absorption of oxygen from the air was extremely slow, but that when the surface was kept gently broken the water was rapidly aerated. Later experiments made in 1921 by Haworth and Hodgkinson, two English engineers, led them to conclude that the surface of air bubbles was not especially suited to permit solution of oxygen from the bubble itself, and that the great change of surface produced at the top of the liquid by rising bubbles probably accounted for the large amount of the solution of oxygen obtained. This was evidently proven to their satisfaction, for they substituted bubbles of nitrogen gas for air and found that the absorption of oxygen into solution still took place. These experiments, with others of a biological nature, indicated that sewage could be successfully aerated by mechanical means as distinct from the use of compressed air.

The first large-scale plant employing mechanical agitation was placed in operation at Sheffield in 1920. The aeration tank had a capacity of about 355,000 British gallons daily. In size it was approximately 201 ft. long by 75 ft. wide, with a depth of 4 ft. It was subdivided into 18 chambers, each 4 ft. wide and with alternate ends connected so that the sewage traveled back and forth a distance of approximately three-quarters of a mile from inlet to outlet ends. Skeleton paddle wheels, one to each channel, on shafts extending across the tank at its center, were used to agitate and propel the sewage. By the action of the paddle wheels the sewage was caused to circulate continuously back and forth from one channel to another at a velocity of about 1.7 ft. per second. Thus the liquid was agitated and rapid surface changes were created. The purification obtained was considered generally satisfactory, as a well oxidized and non-putrescible effluent was produced.

Keeping Sludge in Suspension.—The reactions which occur in a tank of this type have been compared with those which take place in a flowing river, wherein sewage is received and purified by the natural processes at work. However, aeration of sewage in channels like that in a river has its difficulties. Activated sludge sinks at approximately the rate of one inch per minute. Thus, at a velocity of 1½ ft. per second, sewage will have traversed 90 ft. before the sludge has settled an inch. Therefore, linear velocity alone aids very little in keeping sludge in suspension.

In order to overcome the tendency of sludge to settle and at the same time to expose a greater surface for aeration, a spiral flow has been imparted to the liquid. This, as already explained, has been obtained in the case of tanks using compressed air by placing the diffusers to one side. In certain English plants, where the aeration tanks consist of long channels, there is in use what is termed a high-efficiency inclined paddle. One of these paddles is located at the U-bend or return end

of each channel. In action, it propels the sewage with high mechanical and hydraulic efficiency around the bend and along the channel. At intervals along each channel are placed straight, flat plates. They are virtually immersed in the liquid at an angle inclined to the flow. They produce a perfect rotary flow and permit a reduction of the linear velocity from 1.5 ft. per second to 0.5 ft. per second without tendency to settlement on the part of the sludge. It is reported that the process using this device and known as the Hartley spiral flow process, has been found to give results very nearly equal to that obtained with compressed air with the same period of contact and at only half the power.

There are now two types of mechanical aerators which are being introduced to American practice. One is known as the Simplex surface aerator and the other is the Link-Belt aerator.

Simplex Surface Aerator.—In his early experiments, Haworth used a vertical cylinder equipped with a propeller which could be rotated rapidly to induce circulation. The flow through the cylinder was downward, with the return flow taking place in the tank outside. Mr. Bolton, manager of the sewage works at Bury, and the Ames Crosta Engineering Co. developed a similar machine, but with an upward circulation. This machine is now known as the Simplex surface aerator. It consists of a stationary cylinder or uptake tube, 2 ft. 6 in. in diameter, with the exception of the bottom, where it is enlarged in the form of a cone. At the surface is a revolving disc, 5 ft. in diameter, fitted with vanes, designed to throw a thin upper and lower sheet of liquid across the surface of the tank. As the sewage which is being sprayed strikes the surface of the liquid in the tank, numerous air bubbles are formed. In addition, there is set up a downward circular motion of the sewage, which mixes the activated sludge with the incoming raw sewage. All liquid thrown out by the revolving cone comes through the uptake tube from the bottom of the tank, assuring positive circulation. The machine is usually installed in tanks 22 ft. square by about 15 ft. deep. Power consumption approximates 14 kwh. per million gallons of sewage treated.

There are a number of installations of Simplex aerators that are in operation and giving excellent results. So far it is the only mechanical aerator that has been adopted for use in this country.

Link-Belt Aerator.—The Link-Belt Co. of Philadelphia has recently developed a new type of aerator which offers much of promise. It produces the spiral form of circulation similar to that already described. It differs in practically no way from the "spiral flow process" as developed by Hurd at Indianapolis, with the exception that purely mechanical means are used instead of diffused air.

Agitation and circulation are produced by the action of a revolving, paddle-like element of small diameter, located at one side and extending the whole length of a tank. The blades of the paddle are in the form of a comparatively narrow, broken ribbon, pitched both ways. The center of the shaft that carries the paddle blades is located a few inches above the surface of the liquid at a distance of approximately 3 ft. from the side of the tank. The outside diameter of the cylindrical surface formed by the paddle blades when they revolve is about 26 in.

A vertical baffle wall is used to prevent short circuiting of liquid in circulation. This wall is placed parallel to and at a distance of 18 in. from the wall of the tank. It extends from a point a few inches above the surface of the water to within 18 in. of the bottom of the tank. A metal apron, curved to conform with the path of the paddles, extends from the baffle wall, underneath the rotating mechanism about two-thirds of the way to the surface of the water. Upon starting up the paddles the sewage is drawn over a weir located at the top of the baffle wall and forced across the tank on the surface at a velocity of approximately 2.5 ft. per second. Upon reaching the opposite side of the tank it meets a deflector, which directs it downward. It then sweeps across the bottom of the tank and rises up behind the baffle wall to meet the paddles again. It is in this manner that a spiral flow is created, which begins the moment the sewage enters the tank and does not cease until it leaves it. Thorough agitation and surface aeration are therefore accomplished.

The bottom velocity has been found by test to be a minimum of approximately 1.5 ft. per second, which is sufficient to prevent settlement or the accumulation of solids. Power consumption is estimated at 14 kwh. per million gallons of sewage treated.

Other Adaptations.—So far, the discussion on mechanical aeration has been in conjunction with activated sludge plants only. This discussion would not be complete without bringing up the possibilities of mechanical aeration as applied to existing plants having settling tanks for primary treatment and sprinkling filter beds for secondary treatment.

Link-Belt Mechanical Aerator at Maywood Plant of the Sanitary District of Chicago, in Operation. Capacity 52,400 Gal. Per Day; Detention Period Six Hours

The development of communities has, in numerous instances, been so great that the capacities of their sewage treatment plants have been reached and exceeded in much less than the estimated time. While the problem in these instances is entirely one of finances, the burden falls on the engineer, who must devise ways and means of overcoming the difficulty at the lowest possible cost, since in some instances a plant extension is required before the bonds covering the original plant have been retired.

Pre-aeration of settled sewage prior to its application to the sprinkling filter beds appears to offer at least a partial solution of this problem. By aerating the settled sewage for periods approximating one hour, the reduction in the b.o.d. of the settled sewage approximates 25 to 30 per cent. This reduction in b.o.d. is apparently due to the absorption of oxygen by numerous exposures to the air of the sewage.

Aeration partly accomplishes the biochemical decomposition of organic mat-

A Simplex Unit at Princeton in Operation

ter by the utilization of dissolved oxygen through bacterial activities on an aerobic basis and in effect accomplishes the same results as are obtained in the upper section of a sprinkling filter bed.

The amount of oxygen absorbed by surface aeration is a function of turbulence, area and time. Turbulence is obtained in mechanical aeration by the rapid breaking up and throwing of the sewage across the surface of the tank. Area and time would naturally be determined for each installation and would depend on the character of the settled sewage and the aeration required.

Some idea of the rapid exposure obtained with mechanical aeration can be had by considering a tank, say 15 ft. wide by 60 ft. long, at an average surface velocity of 2½ ft. per second. This would require 6 seconds to make a surface change, which would be equal to 10 per minute or 600 per hour. With a surface area of 15×60 or 900 sq. ft., this is equivalent to 540,000 sq. ft. or approximately 12 acres per hour, or 288 acres per day.

So far, several plants have considered this possibility and experiments conducted have proven that oxygen is absorbed by aeration. Therefore, aeration of the sewage between the settling tanks and the sprinkling filter beds should decrease the b.o.d. of the sewage as applied to the beds and should allow an increased loading on the beds by an amount approximately equal to the reduction obtained by aeration.

Application to Activated Sludge Plant.—It may be of interest to describe a treatment plant of the activated sludge type, using mechanical aeration. This plant is shown in perspective in an accompanying illustration and is now under contract for construction. As the effluent from the plant is discharged into a small brook an extremely high degree of treatment was required by the department of health for approval of the plans. In brief, it is anticipated that the final effluent will be colorless and clear and will have at least a 10-day stability and bacteria absent in 50 cc.

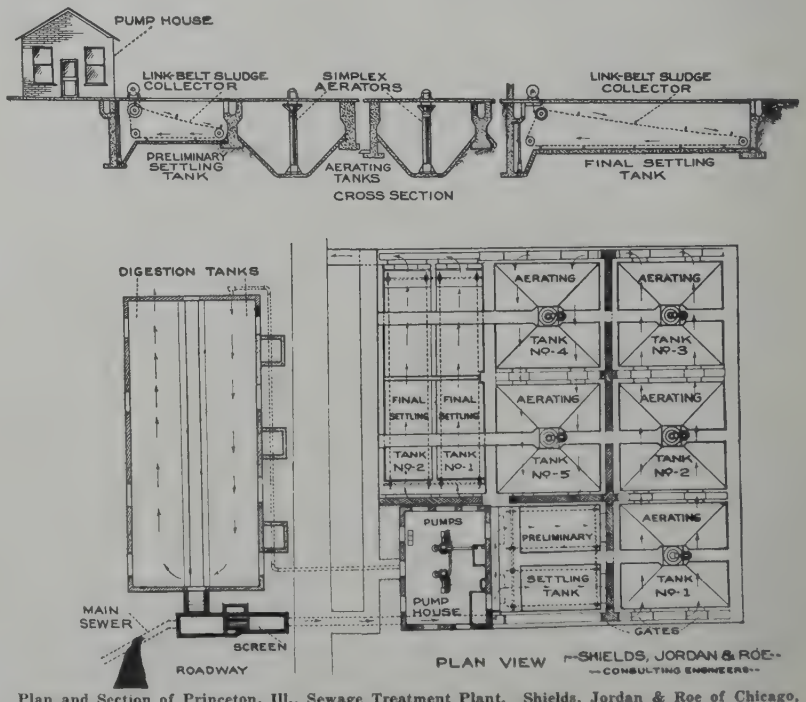
The plant is designed for a capacity of 600,000 gal. per day and a population of 6,000. Units of treatment consist of:

1. Preliminary clarification tank, having a detention period of one hour.
2. Aeration tanks having an aerating period of 6 hours, including 25 per cent return sludge.
3. Final settling tanks having a detention period of 1½ hours with 25 per cent returned sludge.
4. Rapid sand filters, operating at the rate of 1½ gal. per sq. ft. per minute.
5. Contact tank for sterilization, having a detention period of 30 minutes.
6. Sludge digestion tank based on 2.0 cu. ft. per capita with heating coils and gas collection.
7. Glass covered sludge drying beds.

The preliminary clarification tank is preceded by a bar screen and a sand trap. The tank is divided into two separate compartments having hoppered bottoms for the accumulation of settled sludge, the withdrawal of which is effected by sludge piping operating under a hydrostatic head of 4 ft. The effluent from the tank is discharged into a sewage diversion chamber, designed to divert equal volumes of sewage to each of the aeration tanks.

Mechanical Aeration.—The aeration tanks are divided into three separate compartments, each equipped with a Link-Belt aerator. Activated sludge return piping has been arranged so that the point of application can be varied, as it may prove to be decidedly beneficial to aerate the sewage prior to the application of activated sludge. The effluent from each compartment is discharged over weirs and piped to the final settling tanks.

The final settling tank is also divided into three separate compartments, each compartment being equipped with mechanical scrapers for the concentration of the settled sludge. The sludge is collected in hoppers located at the influent end of the tank and is removed through a vertical sludge pipe connected to a sludge channel. The upper part of this pipe has an adjustable section, which contains a V-notch weir over which the sludge is discharged. The



Plan and Section of Princeton, Ill., Sewage Treatment Plant. Shields, Jordan & Roe of Chicago, Consulting Engineers

position of this weir can be adjusted to meet almost any sludge return rate. The effluent from the tank spills over weirs and is piped to the rapid sand filter beds.

Rapid Sand Filters.—There are four rapid sand filters, each having an area of 70 sq. ft., giving a total area of 280 sq. ft. These rapid sand filters are identical with those used in a water works and are equipped with filter sand, graded gravel, manifold system, rate controllers, loss-of-head and rate-of-flow gauges, etc. An automatic closing-off device is provided to function during periods of low flow so as to prevent the level of the sewage from falling below the sand line. Washing of the filter is accomplished by a wash-water pump and the waste wash water is discharged into a reservoir placed under the filter beds, from which it is pumped out at a very slow rate and returned to the influent end of the plant. The filters are housed in a building which will also house the chlorinating apparatus, the air compressor units for sludge lifts, laboratory equipment, etc.

The effluent from the filters is chlorinated and piped to a contact tank, from which it discharges through the outfall sewer to the brook.

Sludge return from the final settling tank is effected by piping the sludge to a sump, in which is placed an air lift to lift the sludge into a sludge diversion chamber, from which it flows over three V-notch weirs, one for each compartment. It is then piped to the aeration tank and surplus sludge piped to the sludge digestion tank. Sludge from the clarification tanks is also piped to a compartment alongside the activated sludge sump and lifted up and discharged to the sludge digestion tank.

Sludge Digestion Tank.—The sludge digestion tank is divided into two separate compartments. Each compartment is divided into channels by baffles, placed so as to obtain a roundabout passage for the sludge. Raw sludge from the clarification tank and excess activated sludge are piped to the influent end of either compartment so that they are mixed as they enter the tank. Arrangements for seeding with digested sludge have been provided and consist of an air lift placed in the sludge discharge pipe, which lifts the sludge into a compartment from which it is piped to the influent end of the digestion tank. Digested sludge is discharged under a hydrostatic head of 4 ft. to a channel connected to each sludge drying bed. Supernatant liquor will be removed by means of a rotary type decanting valve designed so that liquor can be taken off at 6-in. depth intervals throughout the full depth of the tank.

Heating coils have been provided for each compartment, consisting of 1½-in. wrought pipe laid in the bottom of the channels. The entire tank will be practically gas tight and will be provided with gas domes to collect the gas. These are manifolded and piped to a gas-fired hot water boiler placed in a boiler room alongside of the sludge digestion tank. Pressure relief tank, condensation traps and fire traps, have been included with the boiler room equipment, together with gas and water meters, circulating pump, heat regulating apparatus, etc.

Glass Covered Drying Beds.—The sludge drying bed is of the glass covered type and is divided into six compartments. The beds are of the conventional type, consisting of 6 in. of sand supported on 9 in. of graded gravel. Each bed contains an open-joint underdrain piped to a main drain, which in turn discharges into the waste wash-water storage tank under the filter building. Drained liquor is pumped back to the influent end of the treatment plant.

Means have been provided for bypassing excess activated sludge during the summer months direct to the sludge drying beds, provided the direct drying of the sludge can be effected in this manner.

The cost of this plant, having a capacity of 600,000 gal. a day, was only $97,000.

Acknowledgment.—The foregoing paper was presented at the 14th annual meeting of the New Jersey Sewage Works Association, held on March 22 and 23 at Trenton.

Water Softening and Purification at Columbus, O.

During 1928 an average of 29.4 million gal. of water was softened and filtered by the Water Works of Columbus, O. This represents 98 gal. per capita per day. The following details of the work are taken from the report Charles P. Hoover, Chemist in charge:

Hardness of Water.—The hardness of the water was reduced from an average of 242 parts per million to an average of 86 parts per million. A reduction of 64 per cent.

Quantity of Chemicals Used and Their Cost.—To reduce the hardness of the water from an average of 242 parts per million to 86 parts per million, 2,673 tons of soda-ash and 7,991 tons of lime were required. The price paid for soda-ash was $27.74 per ton, and the price paid for lime was $6.52 per ton, making the total cost for soda-ash $74,149.02 and the total cost for lime $52,101.02. The cost of lime, soda-ash, alum and chlorine per one million gallons of water treated amounted to $13.67.

Turbidity and Color Removed.—The average turbidity or muddiness of the river water during the year was 108 parts per million, whereas the turbidity of the filtered water was zero. The average turbidity has been higher during the past three years than in former years. This is due to the O'Shaughnessy dam which holds back the flood water, causing the water coming to the plant to be muddier for longer periods of time. The average color present in the above water derived from decay of vegetation, was 23 parts per million. By the combined use of lime, soda-ash and alum, the color was reduced in the filtered water to one part per million. A color of one part per million is not noticeable to the consumer.

Typhoid Fever.—There were five deaths from typhoid fever during the year 1928, three of which were resident and two non-resident. Figuring the population at 299,000 (state bureau of vital statistics estimate) would give the city a total death rate from typhoid fever of 1.7 per 100,000, a resident death rate of 1.0 per 100,000 and a non-resident death rate of 0.7 per 100,000.

Recarbonation Plant.—The recarbonation plant has been operating successfully during the entire year.

For the past 19 years the alkalinity of the filtered water has averaged 55 P. p. m. During 1928 by the aid of recarbonation, it has been possible to reduce the average alkalinity of the filtered water to 43 P. p. m. For 19 years the average reduction of alkalinity has been 66 per cent as compared to 72 per cent during the past year. The filtered water has during the past 19 years carried caustic alkalinity or excess lime to the extent of 5 P. p. m. whereas, with recarbonation there has been no caustic alkalinity. Normal carbonates, which cause trouble due to formation of deposits on filter sand and in distribution pipes and meters, have been reduced to a figure which is well under its solubility limit.

Trouble with filter sand, through which the entire water supply is filtered, due to the grains cementing themselves together and forming hard lumps has we believe, been entirely eliminated. There has been great improvement in the operation of the condensers at the pumping station. In former years it required three days to clean a condenser. Now the job is easily done in one day. Further growth of deposits in the distribution system seems to have ceased. There has been a reduction in the number of meters clogged by carbonate deposits and the cleaning out of hot water coils has been reduced to a minimum.

Methods of Thawing Frozen Hydrant.—A study made recently by the New York State Bureau of Municipal Information, showed that 25 municipalities used steam for thawing frozen hydrants, 10 used electricity, 7 used a commercial hydrant thawing device and 5 used salt, carbide or other material. Two municipalities used alcohol in the hydrants to prevent freezing.

Factors In Cost of Water Mains

Methods Used in Practice and Design

By JAMES P. IRONS
Superintendent Water and Light Department, Topeka, Kan.

IT is my thought that this subject should be treated from the economic viewpoint rather than from the position of detailed costs of the different items involved in the construction of the various classes and types of water mains. With this idea in mind I will give consideration to the various methods used in the practice and design of water mains and their construction.

Too Much Paring Down Costs.—It has been my experience that in the administration of our public works, there has been too much of an effort made to pare down to the very minimum, the first cost of construction of all kinds. This is not done so much by engineers as by public officials in elective offices, who are more or less responsible to the mind of a fickle public, on the various amounts of money expended by them; whether it be for improvements and betterments, or simply for the administration of the various duties their offices may demand.

I have made these statements, not to give you the idea that we should indiscriminately raise the first cost of construction to the point where it is prohibitive; but rather that we should depend upon the recommendations of specialists and that we should also give careful thought to the methods, and their costs, that will have to be used for the maintenance and service of the different types of pipe lines, in years to come.

The Question of Valve Manholes.—Let me offer as an illustration, the question of whether or not to plan for the installation of valve manholes or to use the practice of simply installing a valve box. It seems obvious that it is much more economical in the end to use the manhole installation, even though the first cost is slightly more, for it is much cheaper to simply raise the manhole cover, than to have to remove and replace pavement, and completely uncover the valve every time it needs repairing. I have used the above illustration for the reason that it has been brought before me very forcibly in the last year, inasmuch as we have instituted a continuous system of valve inspection and maintenance and through that we found at least 50 per cent of our valves needed servicing of some kind. The maintenance was made doubly expensive by the fact that very few of the valves had been set in manholes during the original construction.

The Size of Mains.—The question of what size lines to lay in the different parts of the system plays an important part in the cost of water main construction. The thought runs in my mind that to date, we haven't lived long enough to know what to anticipate as the life of a cast iron water pipe under natural conditions. Cast iron water mains, of course, have failed from unnatural conditions such as electrolosis, acid action and other forms of oxidization due to certain local conditions, which in most cases can be remedied. With this fact before us it becomes apparent that we should plan the size of the installation to care for the demands that may be made on it at least 100 years hence. I ask permission to use another illustration. It was very surprising to me to find that in the City of Topeka, where the mains were first laid only 40 years back that one of the streets in the very heart of the business district was serviced with only a 4 in. line. I have reference to distribution lines and not to main feeder lines. From pumping stations; the size of which are automatically controlled either by the volume of water at your disposal at the pumping plant, or by the conditions existing with respect to the relative location of the pumping plant and the distribution system.

Two Main Systems.—To get back to the distribution system; several cities have already gone to the installation of what is known as the two main system, among which are Boston, Chicago, Detroit, New York, Cleveland, St. Louis and several others. This, as is inferred in the name, consists of laying a main on either side of the street behind the curb.

Hydrant Installations. — It would seem that the question of the number and type of hydrant installations should have a prominent place in the planning of distribution systems. I am of the opinion that hydrants should never be set on less than a 6-in. leg and that all the legs should be valved where they leave the main. Careful thought should also be given to the method of setting the hydrant so that adequate drainage will be provided and the drain also protected from the growth of roots, and other natural processes which tend to clog the drain and cause trouble in the operation of the hydrant.

Valves.—The matter of valves now presents itself. As mentioned before I am thoroughly convinced that all valves should be installed in manholes during the original construction. We should give careful consideration to the number and location of valves. It should not be necessary to valve off and kill the service in eight or ten blocks, to repair a broken main in one block, inasmuch as the main was originally laid for service to the consumer, and he has every right to expect an uninterrupted service, and we should prepare to deliver that service.

Establishment of Official Grade.—The planned design of all parts of a distribution, since the lines are generally laid ahead of all real estate development and the paving and sewer projects; must necessarily be dependent on the establishment of an official grade, by the city engineers office and made legal through ordinance by the city commission.

This idea has been in use in several of the larger cities for some time and has, in one way and another, saved them thousands of dollars for the simple reason that it is possible to plan all construction from a given point; and does not necessitate the changing of one plan to conform to another, either before or after the work has been completed. I mention this for the reason that in so many cases we plan and lay our lines then find that after the paving is completed we are without sufficient protection from frost, and thereby are forced to revamp, at a large expense, a part of our completed work.

The various thoughts mentioned in this paper are all vital parts of the cost of water main construction and unless we consider them, as such, we are merely fooling ourselves as to the real costs of our water mains.

Acknowledgment.—The foregoing is an abstract of a paper presented before the Kansas Water Works Association.

Decline in Death Rate at Boston, Mass.—In 1875 the city of Boston published a report of a special medical commission on The Sanitary Condition of Boston, which contains a wealth of suggestive information. At that time the death rate of Boston had varied from a maximum of 31.8 per 1,000 for the year 1872 to a minimum of 22.3 for the year 1867, but giving a mean annual death rate for a ten-year period of about 25 per 1,000. The death rate of Boston for the year 1927 will be about 14 per 1,000, or an annual saving of 11 per 1,000, equivalent, on the estimated population of Boston, to 11.102 deaths.

Earth Current Surveys for New Pipe Lines

Importance of Preliminary Survey of Electrical Conditions

By E. E. MINOR
Chief Engineer, New Haven Water Co., New Haven, Conn.

IN the selection of a route for a new feeder main, geographical and profile studies may not present all of the engineering aspects of the problem which need consideration. Stray currents, which are often overlooked in the location of a new pipe line, may be the governing factor in the eventual life of the pipe. Therefore, they are decidedly worth studying before the pipe line location is definitely decided upon. If hazardous conditions are found on one route, it may be possible to avoid them on another, or as often happens, the stray current hazards can be materially reduced or eliminated before the pipe is laid. An accurate knowledge of all phases of the stray current problem as it affects the new pipe line is also of vital importance in the design and construction of the lien, because mitigative measures can be applied much more easily and cheaply as the line is laid, than they can after the job is once completed.

In developing a water supply for New Haven we have planned a 48-in. pipe line coming into New Haven on the east. This roughly parallels an interurban electric railway for about 5 miles. The soil is for the most part sandy and of relatively high electrical resistivity. Approaching the city we pass under another electric interurban line with the soil changing to low salt water marshes of low resistance, through which our line would pass for about 2,000 ft. and then under a broad tidal estuary, 1,500 ft. in width, to a sandy high resistance soil in the city.

Earth current surveys were made by Albert F. Ganz, Inc., of New York City under the direction of its engineer, C. F. Meyerherm. The results were surprising and we have included the report in this paper, thinking it would be of interest, in a general way, to members of the Association. Here are soil resistances ranging from 420 to 126,000 ohm-centimeters; voltage gradients running from neglible values up to magnitudes of 282 volts per thousand feet. Needless to say, much improvement will be made in these conditions before our pipe is laid. We believe it shows, however, the value of investigating these conditions before installing thousands of dollars in pipe line which would be immediately subject to depreciation from causes which could be partly eliminated and partly guarded against. The report follows:

Report on Electrolysis Survey.—In accordance with our understanding with you we have made a series of electrolysis tests at characteristic points along the route of the proposed North Branford-New Haven water supply main and we give you herewith our report on the results.

The object of the present investigation was to determine: (a) existing stray current gradients in the earth in the territory through which the proposed pipe line will pass; (b) the electrical resistivity of the soil at characteristic points along the route; and (c) the most desirable locations for any electrically insulating joints which might have to be installed in this pipe line in order to minimize stray current electrolysis action on this pipe line.

We understand the proposed water main will be a 48-in. cast iron line laid along Foxon Road, and therefore approximately parallel to the New Haven and Shore Line Railway tracks from North Branford to the junction of Foxon Road and Essex Street, Fair Haven. At the latter point the pipe line will turn into Essex Street which it will follow to Quinnipiac Avenue. At Essex Street and Quinnipiac Avenue, the new line will reduce to 42-in. and then continue by private right of way through the salt meadows bordering the east bank of the Qunnipiac River, crossing the river to Peck Street, New Haven. Along Peck Street, the new North Branford supply line will continue west to Blatchley Avenue where it will connect to a new 24-in. cross main which will run from Grand Avenue through Blatchley Avenue and Willow Street to Whitney Avenue.

Measurements of soil resistivity and of voltage gradients existing in the earth both parallel and at right angles to the proposed pipe line were made at the following characteristic locations:

1. In the salt marsh just east of the New York, New Haven and Hartford R. R. embankment (Shore Line Division).
2. In the high ground just west of Quinnipiac Ave.
3. On Essex Street in the high ground just east of Quinnipiac Ave.
4. On Essex Street approximately 500 feet east of Quinnipiac Ave.
5. Near the junction of Essex Street and Foxon Road.
6. At Foxon near the L. H. Goodrich property.

Soil resistivity tests were made at all of the above locations with the earth-current meter and the regular four terminal earth-current meter electrode inserted in a 2½-inch hole drilled in the earth to approximate pipe depth. Gradient tests were made at four locations with a Rawson voltmeter and a minal earth-current meter electrode inserted in the earth at points 100 ft. apart except at location No. 6 where the spacing had to be reduced to 50 ft.

The results of the tests are given in Table I.

It will be noted that in the salt marsh just east of the New York, New Haven and Hartford Shore Line Division railroad embankment the soil resistivity is exceptionally low averaging only 420 ohm-centimeters. In the slightly higher ground near Quinnipiac Avenue, the soil resistivity was extremely high, averaging 122,400 ohm-centimeters,

Table 1.—Earth Gradient and Soil Resistivity Measurements Along Route of Proposed North Branford-New Haven Water Supply Main, June 20-21, 1928

Location and Character of Soil	Average Soil Resistivity, Ohm-Centimeters	Earth Gradient Volts per Thousand Feet Parallel to Pipe Maximum	Parallel to Pipe Average	Transverse Maximum	Transverse Average
300 ft. west of Quinnipiac Avenue at Essex Street:					
Black meadow mud	420				
Essex Street, just west of Quinnipiac Avenue:					
Red sand and loam	122,400			2.3S 0.4N	0.83S 0.06N
Red sand and loam (60 minutes test)		10.0E 32.0W	3.4E 1.1W		
Essex Street (north side) just east of Quinnipiac Avenue:					
Red sand and loam	126,300	1.2SW	0.83SW	2.4NW 10.0SE	0.77NW 0.98SE
Essex Street (north side) 500 ft. Northeast of Quinnipiac Avenue:					
Red sand and loam	7,520				
Foxon Road, opposite Capella's Gas Station south of Shore Line tracks:					
Red sand and loam	70,600	3.0SW 0.4NE	0.77SW 0.03NE	6.8SE	2.0SE
Foxon Road, 75ft. east of Shore Line Pole No. 176 (L. H. Goodrich property) north of tracks:					
Red clay and sand	58,800	1.0E	0.61E	1.0S 200N	0.05S 8.8N
Red clay and sand (265 minutes test)				62.0S 282N	Neg. 23.0N

west of Quinnipiac Avenue, and 126,300 ohm-centimeters on Essex Street just east of Quinnipiac Avenue. About 300 or 400 feet further east, Essex Street runs through salt marsh and in this locality the soil resistivity averaged 7,520 ohm-centimeters. At Foxon Road and Essex Street, where the new pipe will run parallel and close to the New Haven and Shore Line tracks the soil resistivity averaged 70,600 ohm-centimeters while in the town of Foxon it averaged 58,000 ohm-centimeters.

The tests of voltage gradient in earth showed that in the vicinity of Quinnipiac Avenue there is an extremely high voltage gradient in earth at right angles to the Qunnipiac Avenue trolley tracks of The Connecticut Company, and therefore practically in line with the proposed pipe line. The maximum gradient along the line noted at the locations either side of Quinnipiac Avenue ranged from 1.2 to 32 volts per 1,000 ft., while the maximum gradient at right angles to the line ranged from 0.4 to 10 volts per 1,000 ft.

At Foxon Road and Essex Street the gradients were not as high as they were near Quinnipiac Avenue, but yet the maximum values ranged from 30 volts per thousand feet parallel to the line to 6.8 volts at right angles. At Foxon the maximum gradient parallel to the line was 1.0 volt, while the maximum gradient at right angles to the line exceeded 200 volts per thousand feet in the field north of Foxon Road near the L. H. Goodrich property. This occurred with a New Haven and Shore Line car operating in the immediate vicinity. To determine the actual maximum value attained by this gradient, a six-hour test was made with a special high sensitivity recorder and non-polarized electrodes. At the same time an eighteen-hour record of the potential of the trolley rails referred to earth six feet away from the rail was obtained. This gradient record shows a maximum of 282 volts per thousand feet at this location and the potential test showed the rails reversing to earth at times, becoming as much as 70 volts positive in potential to adjacent earth.

It is evident that at practically all locations where tests were made in the Foxon Road territory the voltage gradients existing in the earth were far in excess of the limitation of one volt per thousand feet ordinarily set for reasonably safe electrolysis conditions. In fact the earth gradients along the route of the proposed North Branford water supply line are so high that it would be practically impossible effectively to protect the proposed pipe line against stray current action under existing railway conditions. It is true that generally speaking the soil resistivity is comparatively high and that as a result the existing stray current density in the earth is low. This, however, would merely accentuate trouble on a metallically continuous pipe line which would have to run through the low as well as through the high resistance soil. Stray current interchange between such a pipe line and earth would be extremely localized in the soil areas where the resistivity was very low or moderately low.

In addition, the proposed route involves a long exposure to stray currents and since the pipe will be large in size and low in electrical resistance comparatively large amounts of stray current could be picked up even in the high resistivity soil. For this reason any attempt to break up the electrical continuity of the proposed pipe line with isolated insulating joints would be certain to result in high differences in potential across such joints. Even if every pipe joint were made insulating, a gradient of 32 volts per thousand feet parallel to the pipe, such as exists near Quinnipiac Avenue would mean a potential difference of 0.4 volt across each bell joint. Such a potential would be far too high for safety, with any of the practically feasible non-metallic pipe jointing materials like Leadite or Hydro-Tite.

The high voltage gradients existing in the earth in the Foxon Road territory can only be due to an extremely defective track return circuit system on the railway line in this area, and the obvious remedy is the elimination of these defects. In the case of the Quinnipiac Avenue line, we know that the crossing with the New Haven and Shore Line Railway was in bad condition, because an indicating voltmeter test showed a potential as high as 18 volts across this cross-over both in a north to south as well as in an east to west direction. In the case of the New Haven and Shore Line Railway, visual inspection of short sections of track indicated a large number of bonds missing, and the additional possibility of existing bonds having a high electrical resistance because of their being of the pin terminal type whose electrical conductivity is not always perfect to begin with and apt to deteriorate with vibration and age. Another factor tending to radically increase stray currents from the Shore Line system was the comparatively long direct-current feed existing at the time of our tests, due to the Totoket Substation of this trolley being out of service. Apparently this substation was not being operated regularly, and this meant that the entire New Haven and Shore Line Railway was being supplied from the Grand Avenue station of The Connecticut Company in New Haven and a New Haven and Shore Line Substation in Guilford.

Conclusions.—The ultimate safety of the proposed North Branford-New Haven water supply main from stray current hazards demands that the present abnormally excessive track drops existing on the railways in this territory be materially reduced and maintained at a small fraction of their present magnitude. This will involve (a) test of all rail bonds and special work jumper cables, (b) immediate replacement of all missing or defective bonds or special work jumper cables, (c) operation of the Totoket Substation of the New Haven and Shore Line Railway system at least during periods when cars are operating between North Branford and New Haven, and (d) thorough and continuous maintenance of the general electrical conductivity of the track return systems.

Assuming adoption of such railway return circuit improvements as will reduce track drops and earth gradients to reasonable values, it would be well to break up the electrical continuity of the proposed pipe line at several points on both sides of the Quinnipiac River before the line enters the low wet ground bordering the river. From the data which we have obtained so far, the best locations for insulating joints on the east side of the river would be in the high-resistance soil (a) near Essex Street and Foxon Road; (b) just east of Quinnipiac Avenue; and (c) just west of Quinnipiac Avenue. On the west side of the Quinnipiac River, we understand the line will run in clean river sand along the greater part of Peck Street, and several insulating joints should be installed in this section at locations where the soil resistivity is high and where the joints will not be by-passed by connections to the general water distribution system.

Since the expense of installing insulating joints when a pipe is being laid is comparatively small, we would also suggest the installation of additional insulating joints in the proposed pipe line about 500 ft. either side of the crossing with the New Haven and Shore Line track on Foxon Road near Eastern Street, and in the Town of Foxon at 1,000-ft. intervals along the section where the pipe will closely parallel the trolley tracks.

The electrical effectiveness of all insulating joints should be determined by test both just before and after they are put into the line in order to safeguard against breakdowns resulting from handling. All of the insulating joints and the pipe for a few feet on either side could be covered with an insulating coating of tar or asphalt to increase the length of the earth path around these joints. After the line is complete, tests should be made to ascertain whether or not dangerous shunting action exists at any of the joints. To facilitate the latter tests it would be well to install permanent electrical test stations, as the pipe is laid, approximately midway between each pair of insulating joints. On the river section of the main, one such test station should be installed 200 or 300 ft. west of the easterly insulating joint and another, 200 or 300 ft. east of the westerly insulating joint.

Acknowledgment.—The foregoing is an abstract of a paper presented before the New York Section of the American Water Works Association.

Construction of a Small Reinforced-Concrete Bridge

Span of T-Beam Design Built at Laconia, N. H.

By CHARLES A. FRENCH
City Engineer and Superintendent of Public Works, Laconia, N. H.

IN December of last year the city of Laconia, N. H., completed the new reinforced-concrete Church St. bridge, spanning the Winnipesaukee River. This is one of the most important stream crossings in the city and carries the Daniel Webster Highway, the central trunk-line highway of New Hampshire, which is subjected to very heavy traffic.

Replaces Old Timber Trestle.—The river at this point has been spanned since 1840 by a timber bridge resting on mud sills on the river bottom, with split stone abutments at either end resting on logs embedded in the river bed. It had been found necessary to renew this structure at frequent intervals, and the resultant expense and annoyance to traffic were considerable. A movement toward replacement of the old structure was begun in 1908, when Sanford E. Thompson prepared plans and specifications for a two-span arch bridge having a total length of 135 ft. and an over-all width of 50 ft. Since the permissible street grade was but 9.8 ft. above the level of the water, it was necessary to design very flat arches. The problem was complicated by the absence of favorable foundation conditions at the ends of the proposed span.

The city council failed to provide appropriate funds to carry out this project and ordered the reconstruction of the timber bridge, which was maintained with great difficulty until 1928.

Reinforced-Concrete Bridge Chosen.—In 1928, because of the increased flow of traffic and heavier loading, it was decided to construct a reinforced-concrete bridge suited to modern traffic conditions. Public sentiment demanded a structure of pleasing appearance at this point, which requirement eliminated some types that might have been built more cheaply.

The department of public works had built previously two T-beam reinforced-concrete bridges at other locations with considerable success and, in view of the conditions existing at this site, it was decided to design a similar structure, to be built by the forces of the department. Because of the limited head room it was necessary to make the depths of the beams as small as possible. In order to satisfy the public demand for a structure of acceptable appearance, the exterior beams were made to resemble arches.

Borings at the abutments and at the pier locations indicated that a coarse gravel bottom existed at from 17 to 20 ft. below water level, overlaid by coarse sand, fine sand and silt, from 6 to 16 ft. in depth.

The river opening of 150 ft. was divided into three spans, each 46 ft. 11 in. in the clear. The bridge was designed for a 20-ton truck loading, with 30 per cent added for impact. The girders were designed as continuous beams, with an expansion joint provided at each abutment. No fill or special surface was provided for the roadway, but traffic was carried directly upon the slab. The concrete may be surfaced later if the wear seems to indicate that this is necessary.

The spans are carried on nine T-beams, 3 ft. 2½ in. in depth and 18 in. wide. The roadway slab is 7½ in. deep.

Church St. Bridge in Laconia, N. H., Carries the Daniel Webster Highway, an Important New England Trunk Line, Across the Winnipesaukee River

This Bridge Consists of T-Beam Spans, but the Exterior Beams Were Made to Resemble Arches in Compliance with the Public Demand for a Bridge of Pleasing Appearance

The slab is cantilevered for a distance of 3 ft. beyond the exterior beams to carry a portion of the sidewalk and the railing. Ornamental lamps are provided at the piers and abutments.

Construction.—It was necessary to close Church St. to all vehicular traffic during construction of the bridge. A foot bridge was built for the use of pedestrians. In general, limited space prevented the storage of much material at the site, and this hampered construction to a certain degree.

Considerable difficulty was afforded in the construction of the piers by a 12-in. sanitary sewer crossing the river through a cast-iron syphon, which conflicted with the location of the piers. Chiefly because of this sewer, it was decided to construct the piers and abutments in unwatered cofferdams. It was necessary to construct two cofferdams for each pier and abutment, as it was found that the material in the river bottom could not otherwise be held around the sewer when the cofferdams were dewatered.

An attempt was made to build timber cofferdams consisting of an inner and an outer shell with fill between, but it was found that the plank sheathing could not be driven deep enough to prevent the blowing up of the bottom of the excavation when pumped out. Lackawanna steel sheet piling was substituted for planking in the inside shells of the cofferdams, and this was successful in preventing blowouts. The cofferdams were excavated to suitable foundation material, which was found at an average depth of 15 ft. below water level.

The piers were built in two sections until the top of the sewer was reached, where the sections were joined into a continuous structure. Additional reinforcement was placed in the piers above the level of the sewer to tie the sections together securely and prevent any possible tendency to split above the sewer. There has been no indication of any settlement or movement of the piers or abutments since construction.

Local sand and crushed stone were used for concrete aggregate. The concrete was mixed in the approximate proportion of 1:2.5:3.5. About 6 gal. of water were used per bag of cement, and the proportions of aggregates were varied to secure a workable mixture for the various portions of the structure.

All forms, including forms for the balustrades, were fabricated on the job. The balustrades were poured in place. All exposed surfaces were rubbed with carborundum brick to remove form marks and secure a pleasing finish.

Work was commenced on April 20, 1928, and was finished Dec. 3. Traffic was allowed over the structure Oct. 17. The construction of the cofferdams for the piers was necessarily slow and accounted for a large part of the time consumed. Some delay was caused by cold weather in the latter part of November, which retarded the removal of the balustrade forms and the finishing.

Cost.—The total cost of the project was $43,932.60, divided as follows:

Demolition of old bridge; construction and removal of foot bridge	$ 664.75
Excavation and cofferdams	17,178.48
Concrete, forms, reinforcing, finishing	21,132.50
Engineering, overhead, insurance, miscellaneous	4,956.87
Total cost	$43,932.60

Personnel.—The bridge was designed by the writer, assisted by Miles N. Clair of the Boston firm of Thompson & Lichtner. Construction was under the supervision of the writer, with Hartley E. Hamm as construction foreman.

Modern Motor Fire Engines

Modern fire-apparatus units have many features in common with conventional motor vehicle practice but perform functions in no wise parallel to those of the ordinary motor vehicle, said Charles Fox, of the Ahrens-Fox Fire Engine Co., at a recent meeting of the Dayton Section of the Society of Automotive Engineers.

Motorization of fire departments began in a rather desultory way about 1910, and in time gasoline-powered fire engines "made good," considerably before the fact was conceded by the fire commissioners and chiefs. The way for complete motorization of the fire departments was paved by motor ladder-trucks, hose wagons, chemical engines and the like.

Three distinctly different types of pumps are now in general use on motor fire engines, according to Mr. Fox. These are the piston, the rotary, and the centrifugal types. The effect upon the powerplant incidental to the varying relation between volume and pressure is comparable, he said, with the varying load on the engine of an automobile when traveling on the road. When the pumps go into action, the volume of water discharged represents a moving weight, and the pressure at which the water leaves the pumps is the equivalent of a definite vertical height through which the weight is transported. Thus the volume and pressure constitute the load of the pump.

Zoned Municipalities in the United States

The Latest Government Report on Zoning Progress

MORE than 37,000,000 people, residing in 754 cities, towns and villages, comprising three-fifths of the urban population of the United States, now have the protection afforded by zoning regulations, according to a survey just completed by the Division of Building and Housing of the Department of Commerce. The zoned municipalities mentioned above include cities, towns and villages of various sizes and types located in all parts of the country. The results of the survey have been made public in the form of a bulletin compiled by Norman L. Knauss, and issued on April 1 by the Division of Building and Housing, of which James S. Taylor is acting chief. The notes following are taken from the bulletin.

Zoning Progress to 1928.—Viewing the progress of zoning in the United States from the standpoint of ordinances adopted, the eight zoned cities by the end of 1916 were augmented to 38 in 1920. The number of zoned municipalities was doubled in 1921, the total being 76. In 1922 New Jersey, New York, Illinois and Massachusetts showed considerable activity, the additions amounting to 101, which increased the total number of zoned municipalities to 177. During 1923, cities in California and Illinois were more active than in the preceding year, while cities in New York, New Jersey and Massachusetts were less active—but with other states zoning, many for the first time, the year netted 106 zoning ordinances and brought the total to 283. In 1924 76 municipalities adopted zoning ordinances; in 1925 there was increased activity in zoning legislation in the states of Connecticut, Indiana, Iowa and Pennsylvania, and zoning ordinances were adopted by 109 municipalities. Ninety-six municipalities zoned in 1926; 107 zoned in 1927; and 87 municipalities were reported having zoned in 1928; bringing the total number of zoned municipalities to 754.

Zoning During 1928.—Eighty-seven cities, towns and villages were reported to the Division of Building and Housing as having zoned during 1928; while 101 other municipalities were reported as having either adopted more comprehensive zoning ordinances or amended existing ordinance thereby making their zoning more effective.

An analysis of the 87 zoning ordinances reveals that 44 were comprehensive, regulating the use, height, and area of buildings; 27 merely controlled the use of buildings; seven regulated the use and area of buildings; and two were interim ordinances, adopted pending the more careful preparation of zoning ordinance looking to the future.

As a result of either the amendments or the revision of their zoning ordinances, 77 of the 101 zoned municipalities, that originally zoned prior to 1928, now have comprehensive zoning ordinances in effect.

Reports received from all parts of the country indicate a continuing zoning activity in all states. New York state not only leads with a total of 131 zoned municipalities, but also excelled all of the states in the number of municipalities zoned during 1928, with 23 zoned cities, towns and villages. Ohio and Pennsylvania were tied for second place, with six each.

Youngstown, O., Waterbury, Conn., and Altoona, Pa., were three of the largest cities which enacted zoning legislation. Cleveland, O., passed a comprehensive zoning ordinance on Oct. 1, 1928, but the ordinance was made inoperative on Nov. 26 upon the filing of a referendum petition thereon. A new ordinance, almost identical with the one repealed, was introduced on Nov. 16, but had not been adopted by the end of the year.

South Dakota and Idaho were added to the states having zoned municipalities when four cities in the former and three cities of the latter adopted zoning ordinances during the year.

Maryland and Georgia showed progress in county zoning. Prince Georges and Montgomery counties, Maryland, put comprehensive zoning ordinances into effect in areas adjacent to the city of Washington, D. C., and Glynn county, Georgia, adopted such an ordinance applying to its entire area. Township zoning in Pennsylvania has shown progress, with a comprehensive zoning ordinance for Radnor Township added in 1928.

Zoned Municipalities Grouped According to Population.—In grouping the zoned municipalities according to population it was found that 56 of the 68 largest cities having over 100,000 population (1920 Census) were zoned. The zoned municipalities in the population groups total as follows:

- 56 cities having over 100,000 population;
- 79 cities having less than 100,000, but more than 40,000 population;
- 86 cities and towns, having less than 40,000, but more than 20,000 population;
- 96 municipalities having less than 20,000, but more than 10,000 population;
- 132 municipalities having less than 10,000, but more than 5,000 population;
- 89 municipalities having less than 5,000, but more than 3,000 population;
- 119 municipalities having less than 3,000, but more than 1,000 population; and
- 97 municipalities having less than 1,000 population.

New York State Leads.—New York state still leads in the number of zoned municipalities. Massachusetts, New Jersey, Pennsylvania, Ohio, Illinois, Kansas, Wisconsin and California also rank high.

Most Active States Since 1916.—Ordinances regulating the height, and also the use of buildings were adopted prior to the enactment of the first comprehensive zoning ordinance enacted by New York City. Since then, the states showing the greatest zoning activity have been as follows:

- 1917—California, 4 zoned municipalities;
- 1919—California and Wisconsin, 2 each;
- 1920—New Jersey, 4; and California and New York, 3 each;
- 1921—New Jersey, 19; New York, 7;
- 1922—New Jersey, 30; New York, 22; Illinois, 10; Massachusetts, 8; and Ohio, 6;
- 1923—New Jersey, 19; Illinois and New York, 16 each; and California, 15;
- 1924—Illinois and New York, 13 each; Massachusetts, 10; California, 7; and Iowa and Pennsylvania, 5 each;
- 1925—Pennsylvania, 17; Massachusetts, 16; New York, 13; and California and Massachusetts, 8 each;
- 1926—Illinois and New York, 16 each; and Kansas, Massachusetts and Pennsylvania, 6 each;
- 1927—New York, 16; California, 12; Massachusetts, 10; Kansas, 9; and Pennsylvania, 8; and
- 1928—New York, 23; and Indiana, Ohio and Pennsylvania, 6 each.

States Having Most Zoned Municipalities.—When the states are listed according to the number of zoned municipalities, New York leads by a substantial margin, having a total of 131 zoned municipalities. New Jersey is second with 84 places; California, third with 73; Illinois, fourth with 71; Massachusetts, fifth with 62; Pennsylvania, sixth with 43; Ohio, seventh with 41; Michigan, eighth with 31; Wisconsin, ninth with 30; and Kansas, tenth with 23. Then follow Connecticut and Indiana, 17 each; Iowa, 14; Florida, 12; Rhode Island, 9; Missouri and Virginia,

8 each; Nebraska and Oklahoma, 7 each; North Carolina, 6; Colorado, 5; Alabama, North Dakota, South Dakota, and Tennessee, 4 each; Georgia, Idaho, Maryland, Minnesota, New Hampshire, Oregon, Utah and Washington, 3 each; Arizona, Arkansas, Kentucky and Maine, 2 each; and Delaware, District of Columbia, Louisiana, Mississippi, Nevada, South Carolina and Texas, 1 each.

Majority of Zoning Ordinances are Comprehensive.—An examination of the zoning ordinances of the 754 municipalities noted in the survey disclosed that 475 were comprehensive in scope, regulating the use, height and area of buildings. Of the 279 other zoning ordinances, most controlled the use to which buildings and premises could be put, although 45 of the number also controlled the area of buildings; and 10 others controlled the use and height of buildings.

Few Changes Made in Zoning Ordinances.—Questionnaires were sent to all municipalities throughout the United States having authority to zone under state zoning enabling acts. Most of the municipalities that had enacted zoning ordinances prior to 1928 reported that the early zoning ordinances were still in effect. A few cities stated that minor changes had been made in their zoning ordinances, as, for instance, the extending of the boundaries of the various districts, principally in regard to the use districts, wherein the use of buildings and grounds were controlled. A few others reported having revised their zoning ordinances as, for example, enacting a comprehensive zoning ordinance regulating the use, height and area of buildings, taking the place of an ordinance previously adopted which only controlled the use to which buildings could be put.

Considerable zoning activity was indicated by the returns from municipalities not yet zoned, and in returning the questionnaires, many of the city officials asked for information on the subject.

Court Decision on Permits for Garbage Transportation

An interesting court decision on the issuance of permits to remove and transport garbage in a city, is cited in the March 29 Public Health News. The decision was handed down Aug. 3, 1928, by the Ohio Court of Appeals in the case of the City of Cincinnati et al. v. State ex rel. Moock, 164 N. E. 771.

A section of the municipal ordinances of the city of Cincinnati provided as follows:

> That no person shall remove or carry in or through any of the streets * * * of the city * * * any house dirt or house offal, animal or vegetable, or any refuse substance, from any of the dwelling houses or other places of the city, or carcass of any dead animal, unless the owner of the same shall have procured a permit so to do from the director of public service * * * Provided, however, the provisions hereof shall not apply to any contractor with the city in relation to garbage * * *.
>
> It is hereby made the duty of the contractor with the city * * * to collect and remove * * * all garbage and refuse, animal, fish, or vegetable matter found within the city limits; and also all dead animals which are not removed or disposed of by the owner * * *. Except as herein provided as to dead animals, no other person or party than the city contractor or its agents shall carry, convey, or transport through the streets * * * such materials; and it shall be unlawful for any person to interfere in any manner with the collection and disposal of such materials by the city contractor.

The appellee brought a mandamus action to compel the city manager of Cincinnati to issue to him a permit to remove and transport through the city garbage and refuse. It appeared that the appellee had entered into an arrangement with certain hotels in the city to remove their garbage, for which he paid a small sum, and that he desired to convey the same through the city for feeding to his swine outside of the city. The city had an exclusive contract with a company for the disposal of all the garbage of the city.

The decision of the Court of Appeals sustained the refusal of the permit, such decision being summed up in the concluding paragraph of the opinion as follows:

> Our conclusion is that it is within the police power of the city to control the disposal of the garbage of the city in the way that it does; that the city manager did not abuse his discretion in refusing the permit and granting the exclusive collection to an individual corporation, and that there is no violation of any constitutional rights of the realtor.

To Reduce City Traffic Congestion

Discussing the questions of store-door delivery and reduction of city-street congestion, in the April issue of the S. A. E. Journal, George W. Daniels, of the U. S. Trucking Corp., states that the big manufacturing centers in New York City, such as the garment center, are innumerable congested points. Buildings in these districts house from 10 to 20 tenants each. Some receive one case at a time and others ten, and probably every tenant uses a different truckman. Often the goods are brought from mills having a truckman in the city who delivers for them. That adds other truckmen. Trucks are now loaded at night for the uptown section, and the man who gets to the door first is lucky. If he has to make two deliveries in one building, he can make one promptly, but while the receipt is being signed another truckman beats him out on the second delivery, so he loses from one-half hour to one and one-half hours to make the second delivery.

In any new building of more than one tenant the ground floor should be devoted, says Mr. Daniels, entirely to the receipt and shipment of merchandise, the raw material going into and finished products coming out of that building. There should be one truckman for each building. This man would bring all goods to that one building and he would use only one, two or three trucks where ten create congestion at present.

Ohio Sewage Conference

The third annual Ohio Conference on Sewage Treatment will be held in Canton, O. This decison was reached at a recent meeting of the Conference Executive Committee. Determination of the date was deferred, although two tentative suggestions were made—the week of Oct. 8 and the week of Oct. 22. The meeting will be held in the same week as the Ohio Conference on Water Purification, and dates mutually satisfactory will be selected soon, so timed that those who wish can attend both conferences. The water purification conference will be held in Columbus.

An ever-increasing interest on the part of municipal officials in sewage treatment and plant operation should assure a large attendance.

It is planned to expand the meeting into a two-day session and to include opportunity to inspect the Canton sewage treatment plant and the new Salem plant. The former, under supervision of Charles C. Hommon, formerly with the State Department of Health, comprises Imhoff tanks and trickling filters, and has been in operation about three years. The Salem plant embodies the most modern practice in the activated sludge process and is a new plant—the first of its kind in Ohio.

Collection of Garbage by City Held to Be Governmental Function

The Supreme Court of Oklahoma on April 3, 1928, handed down a decision of considerable interest to municipal officials. The decision was rendered in the case of Oklahoma City vs. Baldwin (273 P. 453) and is cited as follows in Feb. 1, Public Health Reports:

An action to recover was brought against the city of Oklahoma City, it being alleged that property damage and personal injury had been sustained by reason of one of the garbage trucks of the city health department having negligently hit the car of the plaintiff. A recovery was had in the trial court, and the city appealed. There was thus presented to the supreme court for decision the question as to whether or not a city, in collecting its garbage, was acting in a governmental or corporate capacity. The court decided that the city, when collecting garbage, was discharging a governmental function, in the performance of which the city was not liable for the negligent acts of its agents.

The contention was made that, because the city charged a fee for the removal of garbage, it was acting in its corporate capacity, but the court stated that it did not think the fact that there was a charge necessarily made the removal a non-governmental function so as to render the city liable.

Improving the Operation of Water-Treatment Plants in Maryland

State Department of Health Suggests Methods, Checks Results

CLOSE cooperation of the Maryland State Department of Health with the water-supply treatment plants of municipalities throughout the state has resulted in a definite improvement of the operation of these plants, with a consequent reduction in diseases traceable to a lack of adequate sanitary facilities. Periodical inspection of water supplies, education of plant operators, recommendations of routine tests to be made at the plants and the collection of detailed data concerning equipment and operation are the most important steps in the control of treatment plants in Maryland, as outlined by Abel Wolman, Chief Engineer of the department.

Public Supplies Inspected Monthly.—The state is divided into three districts, to each of which a resident engineer is assigned. In addition to his other duties he makes at least monthly inspections of the public water supplies in his district. Now and then a plant will require his attention at more frequent intervals and in some instances for several days at a time. On these visits samples are collected for analyses in the laboratories of the department.

Determinations Recommended to Operators.—The determinations recommended to be made by the plant operators depend upon the qualifications of the individual operator and the nature of the treatment the supply is receiving. When chlorination is required, the dosage is regulated by residual chlorine tests, the aim being to maintain a 0.20-part-per-million residual chlorine at an absorption period of approximately 5 minutes. Where, in addition to chlorination, sedimentation and filtration and possibly softening or acidity control are required, the application of the chemicals is regulated by the well-known jar test.

In recommending outfits for this work to a town, the materials required are listed, and the plant authorities are given the names and addresses of several concerns, when possible, from which they can be purchased.

For determining residual chlorine, the La Motte-Enslow comparator is generaly used. The set consists of six chlorine color-standards with values of 0.1, 0.2, 0.4, 0.6, 0.8 and 1.0 part of chlorine per million, made up in sealed ampoules; three 15-cc. test-tubes; an ampoule of distilled water; a 50-cc. bottle of ortho-tolidine reagent and a calibrated pipette for measuring the reagent. The equipment is contained in a wooden case approximately 8 in. long, 2½ in. wide and 5½ in. high. The top of the block contains three slots, backed by etched glass, for convenience and accuracy in making the test comparisons.

Form Used by the Maryland State Department of Health for Collecting Data on Filtration Plants

For hydrogen-ion concentration determinations, the La Motte block comparator, employing a colorimetric method, is most frequently purchased. The outfit is similar in design and size to the chlorine comparator described above. A knowledge of the general nature of the water acts as a guide in determining the pH range of color-standards applicable to a particular supply.

Field Laboratory Kit.—For the use of the department inspectors, there was recently devised a particularly satisfactory case for carrying the equipment necessary for field determinations of alkalinity, chlorides, CO_2, etc. The case, which is shown in an accompanying illustration, is 19 in. long, 7½ in. wide and 12 in. high. Although it was designed primarily for use in investigative work, it has been found convenient for demonstrations in instructing small plant operators and in enlisting the cooperation of town authorities.

Reports of Operators.—Accompanying are illustrations of an information sheet filled out by filter plant operators and a weekly report form submitted to the offices of the department. The purpose of the information sheet is to have on file, in convenient form, detailed data concerning each plant. These data are checked annually, although important changes that may occur at a plant are recorded at the time they are made. The data contained in the operators' weekly reports, as already suggested, vary in accordance with the nature of the treatment employed and the proficiency of the operator. Operators' re-

Form of Weekly Report Submitted by Filter Plant Operators in Maryland Municipalities to the State Department of Health

ports are acknowledged with such comments as may appear desirable.

Large water treatment and sewage disposal plants are in charge of highly-trained operators who furnish monthly instead of weekly reports. These reports are, of course, in much greater detail than can be expected from the small-plant operators.

Department's Measures Successful.— A review of the typhoid fever record of Maryland seems to indicate that the efforts of the department of health in general are gradually being rewarded. The year 1928 showed by far the lowest typhoid fever incidence in the history of the state. The typhoid and para-typhoid fever mortality for the past year was 5.2 per 100,000 for the state at large, 4.2 for the city of Baltimore and 6.5 for the counties of Maryland. Ten years ago the rate for Maryland was 16.9 per 100,000. Systematic control over the public water supplies of the towns throughout the state may be held accountable for a good share of the decrease.

Political Interests Interfere. — In reckoning the amount of credit attributable to the measures of the State Department of Health here described, Mr. Wolman invites the attention of the observer to the not inconsiderable store of patience that must be brought to the business. Political and factional interests so frequently prove the controlling interests of a community that plant operators who have been fairly well trained have often failed in the past to live through municipal administrative changes. As a result, a good portion of the work of the department dealing with the education of operators and administrators must be repeated. However, those who have watched the progress of the campaign which is gradually spreading health information everywhere are confident that this adverse condition is being eliminated.

Research Work of Engineering Foundation

A science of humanics should be built up by research, it is declared in the annual report of the Engineering Foundation, made public by Director Alfred D. Flinn at 29 West 39th St., New York City.

"Experience," says the report, "is showing year after year the actual usefulness and the much greater possibilities of this joint research organization of our four senior national engineering societies with their 60,000 members.

"Even with small and uncertain resources, many members of these societies on special research committees are making valuable contributions of knowledge for the betterment of engineering and industrial practices. The public benefits, generally unaware.

"Research interests of engineers are not restricted to so-called material things. Improvement of the facilities for living and communicating lifts life steadily to higher intellectual, moral and spiritual levels, and promotes health, happiness and brotherliness. The engineer's studies must include the effects of his technical activities upon his fellow humans and their social organization."

During the year, according to the report, the Foundation continued its aid to researches concerned with arch dams, concrete arches, steel columns for bridges and buildings, blast furnace slags, electrical insulation, lubrication, engineering education, and painting of wood.

It also aided studies of fluid flow, cutting fluids used in cutting metals, engineering vocational selection, and other structural problems. Two new research projects are now under way. One relates to alloys of iron, and will embrace all forms of irons and steels. The other involves the materials, manufacture, and use of wire ropes.

The report tells of the Foundation's increased resources, and of its plans to raise further endowment, saying:

"Since 1915, the Engineering Foundation's capital funds have grown from $200,000 to $620,000 and its income from less than $10,000 a year to more than $30,000. This small income has been supplemented by cash, services, materials, and facilities, worth in the aggregate several times as much, contributed to projects which the Foundation has aided.

"These statements, however, are not the whole story. A number of engineers and other friends have let it be known that their wills contain direct or conditional bequests, and the number is increasing. These prospects for the future are encouraging.

"An Endowment Committee, appointed by the United Engineering Society for the Founder Societies has for members sixteen prominent engineers with Colonel E. A. Simmons, member of the American Society of Civil Engineers and the American Society of Mechanical Engineers, as chairman.

"This Committee is seeking $5,000,000 for the Engineering Foundation, and $2,000,000 for the Engineering Societies Library by direct gifts of cash or securities, bequests, life insurance, annuities, living trusts, or installment contributions.

"Projects in hand or waiting need substantial funds now; therefore, the Foundation especially invites the attention also of persons preferring donations for expenditure within a stipulated period, believing that the future will be at least as able as the present to provide for its own needs."

Testing Small Water Supplies in Rural Districts

The engineering Division and Division of Laboratories of the Ohio State Department of Health, cooperating with the district health commissioners, are endeavoring to inspect, analyze and report on the condition and safety of the public and semi-public small water supplies found in the rural districts and to mark with the Seal of Safety those found satisfactory. The form of the marker now used to identify safe supplies is a decalcomania of the State of Ohio outlined in yellow. In the center of the design is a yellow disc bearing the words "State of Ohio, Department of Health," near its outer edge, and "Seal of Safety" across the center. Above the yellow disc are the words "Safe Water." The field of the design is printed in gold.

Old Brick Pavements Relaid in Jacksonville

Methods and Costs in Florida City

By W. E. SHEDDAN
City Engineer, Jacksonville, Fla.

THE practice of laying vitrified brick pavements on natural subgrade with sand filler and without special foundation was followed quite generally in Jacksonville. Most of these pavements were constructed from 15 to 30 years ago and have served to carry traffic far in excess of that for which they were designed. With modern traffic and the motoring public demanding smooth riding pavements, city officials are faced with the need for rebuilding these streets and thoroughfares. Our study of this problem in Jacksonville led us to two definite conclusions:

1. Most of these pavements were not of sufficient width to meet modern traffic requirements.
2. The old brick had a definite salvage value and our examination of them indicated to us that from 60 per cent to 85 per cent were usable.

Salvage Quantities High.—The city of Jacksonville had some 50 or more miles of these pavements. It was recommended that certain streets be rebuilt with wider roadways. Forty, fifty and sixty-foot widths were selected, which conform to more or less standard widths used in this city. We are now completing this program and find that we somewhat underestimated the salvage quantities on all streets.

It was found that certain limited areas, constructed 30 or more years ago of small-size brick which were not figured of value in our relay program, actually produced more than 50 per cent reasonably good brick. These brick are usable for repair purposes and could be relaid on suitable foundations for light-traffic streets.

Other streets that have had from 18 to 25 years' service produced salvage quantities of usable brick averaging 75 per cent, and on some streets the salvage quantities exceeded 85 per cent. All these were "repress" brick approximately 3 in. x 4 in. x 8 in. in size which were originally laid on edge but in the relay program were laid flat. They cost when purchased from $21 to $25 per thousand, delivered in Jacksonville and the cost in place was from $1.25 to $1.60 per sq. yd., which is approximately 60 per cent of the present prevailing price.

Relay Bids Close and Low.—The relay program comprises approximately 55,000 sq. yd. or about 2½ miles of 40-ft. roadway. All pavements were relaid on 8-in. compacted Florida limerock base with sand cushion and standard bituminous filler. The old granite curbs were reset, new 20-ft. radii being used.

When this work was advertised the city was fortunate in getting a large list of responsible contractors to bid. The bids were close and low. The prices bid by the three lowest bidders for relaying with standard brick filler on limerock base ranged from 30 ct. to 45 ct. per sq. yd. The prices bid for base, which includes grading and adjustments, were from $1.06 to $1.29, and resetting of old granite curb ran from 11 ct. to 13 ct. The prices bid for new brick, 3-in. vertical fibre with bituminous filler, were from $1.62 to $1.93 with about the same range for base and curb.

The relay projects have more than fulfilled our expectations as to smoothness and general appearance.

Relaying Methods.—The bituminous filler was applied in the ordinary way. One contractor used pouring cans, heating his bitumen in ordinary 500-gallon kettles; another used the ordinary 500-gal. kettles for heating, the bitumen being distributed direct from the kettles by attaching a hose and letting it drag on the brick and spill out. The kettles were pulled with a roller. Both contractors used hot metal squeegees for spreading and cutting the bitumen on the brick surface.

The relay brick required an average of 13½ lb. of bitumen per sq. yd. and the new brick an average of 11½ lb. per sq. yd.

An Old Brick Pavement in Jacksonville Before Relaying. This Shows Duval St., Looking East from Georgia St.

Economy of Relay Program.—We figure that the over-all average cost per square yard for completed pavements on the seven relay projects was $2.44 and the over-all average cost per square yard for completed pavements on the new brick projects was $3.05, showing a difference of 61 ct. per sq. yd. This amounts to a saving to property owners and the city of $33,550 on the seven projects.

The cost shown for new brick is the cost after the salvage value of the old brick taken from these streets has been deducted. This salvage actually amounts to an average of 33 ct. per square yard, which would make the cost of new brick based on these bids $3.38 per square yard, showing that the savings are about equally divided between the streets from which the brick were taken and the streets on which they were used.

In figuring the cost of the relay

Old Brick Relaid on Market St., Jacksonville. This Pavement Was Relaid on an 8-In. Compacted Limerock Base with a 1-In. Sand Cushion and Bituminous Filler

brick, the value of the brick already on these streets and used in the relay was not shown; only the brick added to fill out added width were charged.

Saving was not only effected on the relay streets but also on the streets from which the brick were taken up and replaced with new materials. We credited to the streets from which they were moved, all usable brick at $20 per thousand; this effected from 85 ct. to $1 per front foot saving on these streets. The work was all done on a one-third—two-thirds plan, the city paying one-third of the total cost from bond issue funds and assessing two-thirds of the total cost to abutting property on a per-front-foot basis.

Duval County has utilized this plan in rebuilding county highways, having relaid approximately 30 miles of 16-ft. road on a somewhat similar specification, with about the same results.

Meeting of New York Section Am. W. W. Assoc.—The next meeting of the New York Section of the American Water Works Association is to be held May 2nd and 3rd, 1929, at the Mark Twain Hotel, Elmira, N. Y. Secretary, E. D. Case, The Pitometer Co., 50 Church St., New York, N. Y.

Pacific Northwest Water Works Men to Meet.—The next meeting of the Pacific Northwest Section of the American Water Works Association will be held May 15th and 16th, 1929, at Spokane, Wash. Secretary, Kenneth Shibley, 1005 Securities Building, Seattle, Wash.

Regulations Governing Missouri Public Water Supplies Revised

The regulations of the State Board of Health of Missouri governing public water supplies have been revised recently. The most radical change relates to the bacteriological analysis of public water supplies. As authorized at the present time this applies only to those public water supplies which do not have adequate laboratory facilities.

The present policy of the State Board of Health recognizes that the most satisfactory plan includes a bacteriological water laboratory in conjunction with all surface water purification plants. Until such a condition exists, the new regulations provide for weekly analyses of all public water supplies which require purification and have an adequate laboratory control. Also, regular bacteriological and chemical analyses by the State Board of Health are required for all ground water supplies.

Section 10, Part VI, of the Sanitary Code, governing the analysis required of public water supplies is quoted herewith from March Missouri Public Health News, the official publication of the State Board of Health.

Analysis of Water Required.—Samples of water from public water supplies shall be collected as authorized by the state board of health and examined bacteriologically and chemically at the laboratories of the state board of health. Not less than two samples of water for bacteriological examination and one sample of water for sanitary chemical analysis shall be collected each year from the ground water supplies which do not require purification. Not less than one sample of water each week for bacteriological examination and one sample of water each year for sanitary chemical analysis shall be collected from surface water supplies and ground water supplies that require purification.

The following rules shall govern the analyses of water samples required by this regulation:

(a) Submission of Water Samples. Water specimens for sanitary analysis shall be submitted in containers, furnished by the State Board of Health. Specimens shall be collected and packed in accordance with instructions enclosed in the container. Specimens which are not collected and packed as specified shall be discarded.

(b) Transportation Charges on Specimens. The owner submitting specimens to the State Board of Health Laboratories for analysis shall pay all transportation charges on said specimens. When specimens are submitted in containers which must be shipped by express, the owner submitting the specimens shall pay the transportation charges both from and to the State Board of Health Laboratories.

(c) Fees—Authority For. By virtue of the authority conferred upon the State Board of Health by Section 5778, Revised Statutes of Missouri, 1919, the following fees are established for the sanitary analysis of water specimens as required by this regulation.

(d) Fees—Public Water Supplies. Basis of Charges. 1. The annual fee for the required sanitary analysis of public water supplies, shall be based upon the last estimate of population made by the United States Census Bureau.

2. When the regular sanitary analysis of a public water supply is instituted later in the year than the month of January, the fee for the remainder of the year shall be prorated by months on the basis of the annual charge. The fees for sanitary analyses of water shall be paid in advance.

3. Ground Water Supplies. The fee for the required sanitary analyses of public water supplies of ground origin which do not require purification shall be as follows:

Population of Cities	Per Year
Under 500	$12
500 to 1,000	13
1,000 to 2,000	14
2,000 to 3,000	15
3,000 to 5,000	16
5,000 to 15,000	17
15,000 and above	18

4. Surface Water Supplies. The fee for the required sanitary analyses of public water supplies of surface origin and ground water supplies which require purification shall be as follows:

Population of Cities	Per Year
Under 1,500	$ 40
1,500 to 3,000	60
3,000 to 6,000	80
6,000 to 10,000	90
100,000 and above	100

Elevated Storage for Municipal Water Supply

Considerations in Selection of Elevated Storage Capacity

By DONALD H. MAXWELL
Principal Assistant Engineer, Alvord, Burdick & Howson, Consulting Engineers, Chicago, Ill.

MANY water works plants are undoubtedly under-developed in provision for elevated storage, while a few have perhaps unnecessarily liberal capacity. There appears to be in fact great diversity of practice in this respect.

Disadvantages of Operating Without Elevated Storage.—There are many disadvantages, particularly in the relatively small plant, of operating without elevated storage. The principal disadvantages are the following:

1—With direct pumping, it is necessary in order to maintain pressure to keep the pumps in operation at all times, at a rate equal to the demand. Interruption in power or other failure of pumps or supply at once results in an abrupt pressure drop and cessation of service. This result is always a severe inconvenience and may in case of fire be disastrous.

2—The necessity of following the demand curve with the pumps requires more consistent attendance at the pumps, especially with steam equipment, and does not permit of as good economy as would be possible by operating pumps of the proper capacity at their best efficiency.

3—From the standpoint of good pressure on the distribution system, following the demand curve with the pumps has a disadvantage in that at high pumpage rates, the friction losses between the pumps and consumers necessarily result in lowered pressure. It follows that satisfactory pressures are easily maintained on the distribution system at night and during the early morning hours of low pumpage when not so important, whereas pressures are necessarily less satisfactory during the hours when water is used at a high rate and good pressures would be particularly desirable.

4—With electric pumping, following the demand curve has the further disadvantage of building up a high peak power demand with corresponding unfavorable effect on the power bill. Direct pumping also precludes taking advantage of off-peak power rates, which usually involve a substantial saving.

Purpose of Elevated Storage.—Part or all of these objections to pumping direct may be obviated by elevated storage, the purposes of which may be summarized as follows:

1—To tide over interruption in pumping.

2—To smooth out peaks in demand, both for water and power.

3—For fire protection.

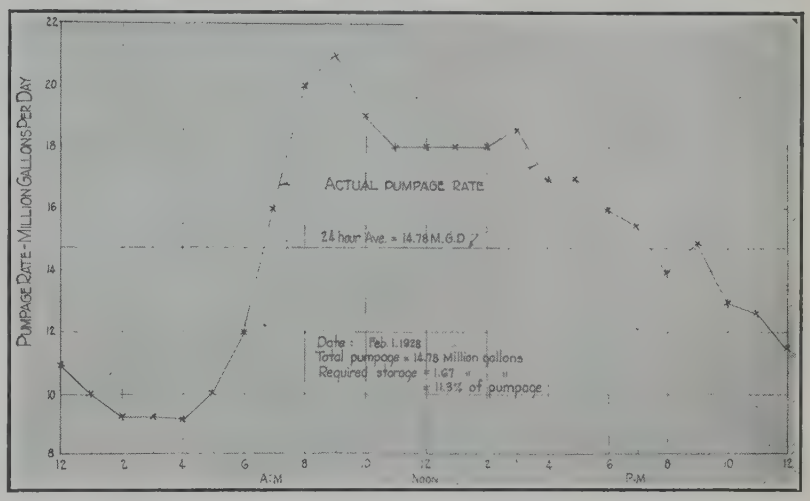

Fig. 1.—Pumpage Characteristics on Typical Approximate Average Day

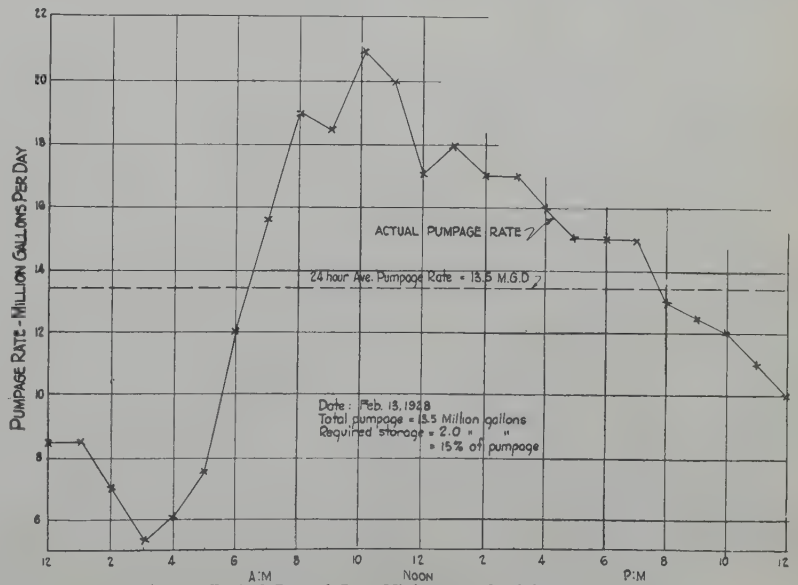
4—To improve pressures.

Capacity of Elevated Storage.—The requirements for the above purposes vary widely with the size and type of plant.

In the small town a single elevated tank of moderate capacity may serve all of the above purposes economically.

In the larger plant, it may be better economy to provide a portion only of the desirable reserve as elevated storage. In very large plants, with steam operation and more than one pumping station, elevated storage becomes of less importance for reserve, but even here may be distinctly valuable to improve pressure distribution. The first step to a rational solution is a consideration of the proper basis for determining the storage capacity to meet each of the purposes listed above.

Tiding Over Interruptions in Pumping.—To meet the contingency of power interruption, the elevated storage



PUMPAGE RATE - MILLION GALLONS PER DAY
ACTUAL PUMPAGE RATE
24 hour Ave. Pumpage Rate = 13.5 M.G.D.
Date: Feb. 13, 1928
Total pumpage = 13.5 Million gallons
Required storage = 2.0 " "
= 15% of pumpage
A.M
Noon
P.M

Fig. 2.—Typical Day of Low Minimum and High Peak Average

should be sufficient to supply the ordinary consumption demands in the interval required for starting the emergency equipment. With electric pumping, this requirement is the minimum that should be provided. Preferably the storage should be extended when practicable so as to reduce dependence on stand-by pumping equipment.

Smoothing Out Peaks With Elevated Storage.—For the purpose of smoothing out the peaks in consumption demand, the required amount of elevated storage is approximately 15 per cent of the 24-hour pumpage rate, in fully metered towns with an average consumption of approximately 100 gal. per capita per day. This will vary with the pumpage characteristics of the particular plant and should be determined in relation thereto. Fig. 1, 2 and 3 illustrate the characteristics in a manufacturing city of about 160,000 population.

Figure 1 represents a typical approximately average day.

Figure 2 shows a typical day of low minimum and high peak pumpage. This shows a minimum rate of 5.3 m.g.d. and a maximum rate of 20.9 m.g.d., the maximum being nearly 400 per cent of the minimum rate.

Figure 3 shows three typical days of heavy pumpage.

On each of these diagrams there is indicated the elevated shortage required to permit the pumps to supply the demand at a uniform pumpage rate.

Leaving out of consideration future growth, the desirable amount of storage is this instance to make uniform pumping practicable is approximately 2 million gal., or about 15 per cent of the 24-hr. pumpage rate.

Smoothing out peaks of the pumpage rate has the following advantage:

1—In connection with electric pumping, it reduces the cost of power by lowering the peak rate of power demand.

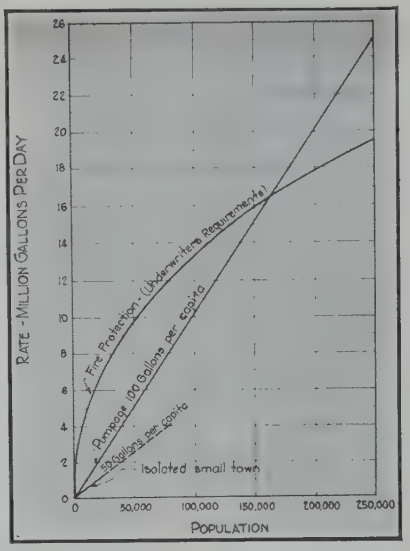


Fig. 3.—Three Typical Days of Heavy Pumpag

2—It reduces the cost of power, whether steam or electric, by permitting operation of properly selected units at maximum efficiency.

3—It increases the efficiency of the distribution system, permitting more uniform pressures to be maintained and providing higher pressures than otherwise possible during peak periods of consumption.

Off-Peak Pumping.—In plants operating on electric power, including cities with suitable high service reservoir sites as well as smaller towns, it may be good economy to include in elevated storage sufficient capacity allowance for shut down of pumps during the on-peak power hours.

Storage for Fire Protection.—In the small plant pumpage rates for fire protection are high relative to the average pumpage for ordinary consumption. This is clearly shown on Fig. 4, which shows the maximum fire demand rate in comparison with ordinary consumption rates, based on 50 gal. and 100 gal. per capita respectively.

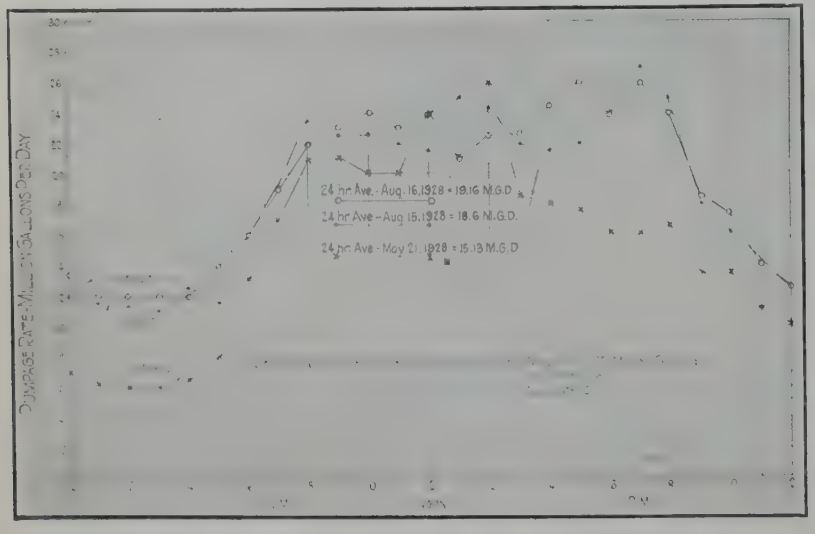

Fig. 4.—Maximum Fire Demand Rate Compared with Ordinary Consumption Rates.

The small plant with a well supply usually cannot furnish the quantity required for fire protection economically, except from storage. In such plants having air lift and in small plants with filtration, a large part of the necessary reserve is frequently carried as low level storage, but this has the disadvantage of too great dependence on pumps and power service, in emergency.

It is practicable in the small plant, and more satisfactory to provide all or a major part of the necessary reserve as elevated storage. This also applies to cities, which have suitable high level reservoir sites.

The storage capacity provided for fire protection should preferably be sufficient to supply the rate of flow called for by the underwriters' requirements, for 10 hours in cities over 2,500 population, and for 5 hours in cities under this population.

Depth of Storage.—Depth of storage should not exceed the permissable pressure variation. Storage below the level corresponding to the minimum pressures maintained, is wasted except as it may be of some value in extreme emergency. Such storage may not entail added cost but where not used is misleading if considered as useful storage.

Location of Elevated Storage.—Elevated storage may be utilized to improve the efficiency of the distribution system, and give better distribution of pressures. This purpose is best served by locating such storage remote from the pumps, and generally speaking, on the opposite side of the principal district served. In this way heavy drafts at intermediate points are supplied from opposite directions, thereby greatly reducing the pressure losses for given flows and correspondingly improving the pressures. To illustrate, if the flow is supplied at a point midway between pumps and elevated storage equal quantities being supplied from each source, the pressure loss at the point of use will be only one-quarter of the corresponding loss if the entire flow is furnished directly from the pumps.

Provision for Future Growth.—Provision of elevated storage should be made adequate for at least ten years in the future, just as would be done with any other major plant improvement. For this purpose, the trend of growth in pumpage and the probable conditions at least ten years in the future should be taken into account.

Acknowledgment.—The foregoing is an abstract of a paper presented at the recent meeting of Rocky Mountain Section of the American Water Works Association.

City Planning As Related to the Smaller Cities

General Procedure and Related Legislation Outlined

By E. A. WOOD
City Planning Consultant, Dallas, Tex.

IN adopting a comprehensive program for its work the National Conference on City Planning has urged each American municipality to do three things: First, provide a city plan commission and office where the commission may take part in the city's administrative machinery; second, prepare and adopt an official city plan; third, secure public support for the administration of the official plan. Such a program may be adapted to any municipality irrespective of size, location or composition. It also clearly shows that the difference in city planning in large and small cities is one of size only. The principles are the same and legislation is equally necessary in either case. There is this difference however—that city planning is easier for the smaller cities to undertake; is more effective, and does not cost nearly so much as in the larger cities.

All cities should be as carefully planned as a modern railway terminal, a suspension bridge or a central lighting plant. But the planning should be done before the city is built. And it should be along regulatory lines before mistakes occur rather than through the corrective method after errors have been permitted. Therefore, if the official plan is prepared in advance of city growth, its enforcement becomes a matter of public support strengthened by the necessary rules and regulations to make it effective in all parts of the city.

Planning Commission First Step.—As pointed out by the National Conference on City Planning, the establishment of a city planning commission is the first step in the planning of a city. Since private property and property rights are involved, a commission is better able to deal with the public than the mayor and board of commissioners. The latter do not have the time to devote to the many problems that arise, nor are they politically free to treat the subject dispassionately. The planning commission should be created by a properly drawn ordinance to give the required official status. Preferably the ordinance should be patterned after "A Standard City Planning Enabling Act," as prepared and published by the United States Department of Commerce.

This act was prepared by an advisory committee whose members have each had many years of first-hand experience in coping with local planning problems, both as citizens and in connection with the leading national business, professional and civic groups which they represent. During the three years' work required to draft the act, the advisory committee made laborious researches into legal problems and consulted with expert planners, members of planning commissions, municipal officials and other interested persons throughout the country. The act, therefore, represents the very best city planning thought, is concise yet brief, and contains the necessary legal phraseology.

Enlist Public Interest.—The relationship of city planning to the smaller city should be real. It should create a lively interest on the part of every citizen. The membership of the planning commission should be carefully selected and should be composed of outstanding citizens who can devote a considerable amount of time to the study of physical conditions on the ground as well as to the numerous meetings that will be required with different groups of individuals. The memberships should be varied and since the plan is to be comprehensive and include all phases of city life, the public schools, park board, women's clubs, chamber of commerce and retail merchants should be represented along with other organizations. Representatives from the city government should be limited to a member of the council and the city engineer. The former should act as a liason agent between the council and the planning commission, and the latter is entitled to membership by virtue of his office. He is also charged with the execution of the plan and to some extent with the enforcement of the commission's rules and regulations. The mayor and city attorney should be members ex-officio, the mayor by virtue of being the head of the council, and the city attorney by reason of his legal training.

The ordinance creating the city planning commission should also establish a budget to provide for the establishment of a city planning office, and the employment of a city planning consultant. The former is necessary to provide working quarters for the commission, a meeting place and a forum for the creation of interest in the official plan. Public interest in the plan is of prime importance, and it is necessary that someone explain the plan, exhibit maps and discuss advantages both pro and con if public interest is to be sustained. Many people respond by giving counter proposals, and thus interest is aroused and held if the work progresses expeditiously. In the smaller city, it is easier to create this interest and hold it because the diversity of objectives common to the big city is lacking. Also, the opportunities for correct planning are more numerous in the smaller city; at least the physical boundaries are more elastic and are more readily molded into the official plan.

Master Plan Essential.—But one must ever be on the alert for mistakes. Therefore, a city planning consultant should be employed, not only to guide and direct the planning, but also to serve as mentor to the city planning commission and the citizens. It is very easy to make mistakes, and early enthusiasm for city planning benefits may lead to serious errors unless held in check by the consultant. The making of a master plan is a matter involving not only all of the land within the city boundaries, but affecting all of the land adjacent to the limits. Therefore, study of an area larger than the city is necessary for the preparation of the master plan.

After the city planning commission has been established and before work has been started on the master plan, there are a number of city planning regulations that may be put into effect. The most important of these are the platting requirements and the zoning ordinance. An early enactment of the platting rules is very desirable because of the failure of individual land owners to coordinate their subdivisions with existing streets, alleys and blocks. This is not due so much to willful neglect as to the lack of foresight and the absence of a master plan to serve as a guide. Coordination of all plans is the outstanding feature of a master plan.

Platting of Property.—The planning commission should prepare and adopt a set of rules governing the platting of property at its earliest opportunity, so that it can exercise the necessary supervision over the individual property owners and coordinate individual efforts. These rules should lay down clearly and concisely the kind of plats to be submitted for approval, together with the scale of the drawing and the information desired. It is necessary that a certificate of ownership be furnished together with ties to existing corners, to locate the property on the master plan. Such rules acquaint the public with the commission's function and methods. To be effective they should also be adopted by the city commission. This gives them legal status.

In Texas, cities of 25,000 population and over now have the power to control platting, not only within the city's

limits, but also for a distance of five miles beyond. In cities of less than 25,000 population, control within the city limits can be obtained by withholding water, sewer or other utility connections until plats conform to the master plan. Continuous streets of proper width without offsets and without dead ends and with blocks of economical size can thus be secured and the plan gradually carried out.

Develop Parks; Preserve Trees.—Additional features might be added to these regulations which would be helpful to the master plan. These are building lines for residences, setbacks for stores adjacent to home areas and the dedication of fractional lots for park purposes. Certain cities now require property owners to dedicate 10 per cent of their additions for park purposes to assist in the development of a park and playground system.

Parkways, boulevards and walkways should be located along creeks and rivulets. The parkway feature is extremely important because it not only furnishes an adeqaute storm sewer system but also adds to the beauty and utility of additions, spreads out the population and reduces the danger from fire. Too frequently this type of regulation is overlooked and subdividers are permitted to fill up dry runs and storm channels, including these in the lots and selling to private owners who have no interest in maintaining them as public ways.

Trees and shrubs are usually found along such channels. These should be preserved as an asset to the city not only from the aesthetic standpoint but also from the utilitarian standpoint of shade and playground space. Natural beauty spots can rarely be improved upon except by cutting out underbrush and making them available to the public.

Establish Building Lines.—The establishment of building lines in residential districts adds materially to the privacy of homes, decreases the dust nuisance, decreases the noise from passing traffic and encourages home beautification through the planting of grass, trees, flowers and shrubs. They decrease the accident hazard to children by providing suitable playgrounds on every lot. They also permit vision clearance for traffic at street intersections.

In suburban and outlying business districts the building line or "setback" permits cars to park "head-in." This gives greater freedom to traffic. It not only removes the parked vehicles from the moving lanes of traffic but also provides for future street widening.

Zoning Ordinance a Prime Requisite.—Zoning regulations should also be enacted before the preparation of the master plan. These deal with the use of private property and not only restrict the ues of the land, but also limit the height of buildings and the density of population. Three general types of usage are recognized in zoning regulations; viz., residential, commercial and industrial—the former being the most restricted use while the last is the least restricted.

In the early days of city life property classifies itself along economic lines and following certain economic laws. Industries and warehouses are established along the railways, while the banks, hotels and stores form a group around the public square. Beyond the stores are the homes of the people. Zoning follows these same laws and prohibits the intermingling of industry, commerce and dwellings. Homes may be built in commercial or industrial districts but commerce or industry can not invade home districts nor can industries invade business districts.

This type of regulation is legal not only in Texas but in the majority of the states because it is based upon the police power of the government which seeks to protect the health, safety, morals and general welfare of the community. This authority was given to Texas cities by its legislature in 1927.

Zoning regulations are meeting a popular demand on the part of home owners for protection. This popularity is shown by the following table showing the number and class of cities in the United States having zoning regulations.

Population	No.
Less than 1,000	53
1,000 to 5,000	144
5,000 to 10,000	102
10,000 to 25,000	103
25,000 to 50,000	79
50,000 to 100,000	47
Over 100,000	55
Total	583

Zoning is an essential part of the master plan. Land is divided into two general classes: public land and private land. The master plan must deal with both classes and unless some measure of control is exerted over the privately owned land, correct city planning cannot be had nor can proper provision be made for the expansion of streets and public utilities.

Once the character of the various sections of the city is established by zoning, the street plan, the park, boulevard and playground sytem, the school locations and the civic center can be designed and laid out as an integral part of the master plan which gives the picture of the future city. Of course it will need to be expanded from time to time and even supplemented or changed. Nor will the work of the city plan commission ever be finished. It will continue from one year to the next, attempting to provide plans in advance of actual growth.

Public Must Favor Plan.—Public support is necessary for any city plan and the master plan must be sold to the public, else it will never be carried out. Experience in many cities bears out this statement and it is sometimes said that it is better to have more selling and less planning. At any rate, the essential point is to sell the community on the advantages of planning and a master plan. Citizens will then demand the plan before they will permit the expenditure of public funds for uncoordinated work. This is particularly true of the smaller cities whose public funds are limited.

Acknowledgment.—The foregoing is a paper presented at the spring meeting of the American Society of Civil Engineers at Dallas, Tex., on April 25.

The Planning Foundation of America

When the movement for better city planning began to gather headway in the 1900's, the needs and problems of the cities' congested populations and movement were recognized as appalling enough to demand the establishment of a central forum for their discussion and formulation. In 1910 the National Conference on City Planning was organized. As the planning interests of the country expanded, the Conference became the center for research, advice and information to the extent of its limited financial resources.

But there is no easy solution for these grave municipal problems, and the necessity for an adequately equipped central organization devoted solely to the study and guidance of city and regional planning in the United States has been increasingly apparent. Frederick J. Keppel, president of the Carnegie Corporation, in his annual report for 1928, points out that each year's experience "reinforces the conviction that additional foundations are needed, particularly of relatively limited objective, and not necessarily of large capitalization;" and quoting from his annual report of 1926, Mr. Keppel specifies among other requirements studies in rural life, in recreation, and in town and regional planning.

It was proposed, therefore, in 1928, to erect a Planning Foundation to expand the service program already operated by the Conference, and with the larger resources of such a foundation increase the service of the Conference in proportion to the planning needs of the country.

The Planning Foundation of America will not teach people how to pave streets or build private houses and city halls. It will not instruct them how to finance the acquirements of parks, or the enlargement of water supply systems. Capable agencies exist for these purposes. The Foundation's object is to bring together the facts, figures and experiences of city and regional planning, wherever they exist, study them, coordinate them, and place them at the disposal of the public as authoritative planning guides. When the problems of city planning are so treated the movement for orderly city growth will reach its goal on a sound economical basis.

New Safety Zones Protect Pedestrians and Trolley Passengers in Toronto

Electric Beacons of Unusual Design Installed

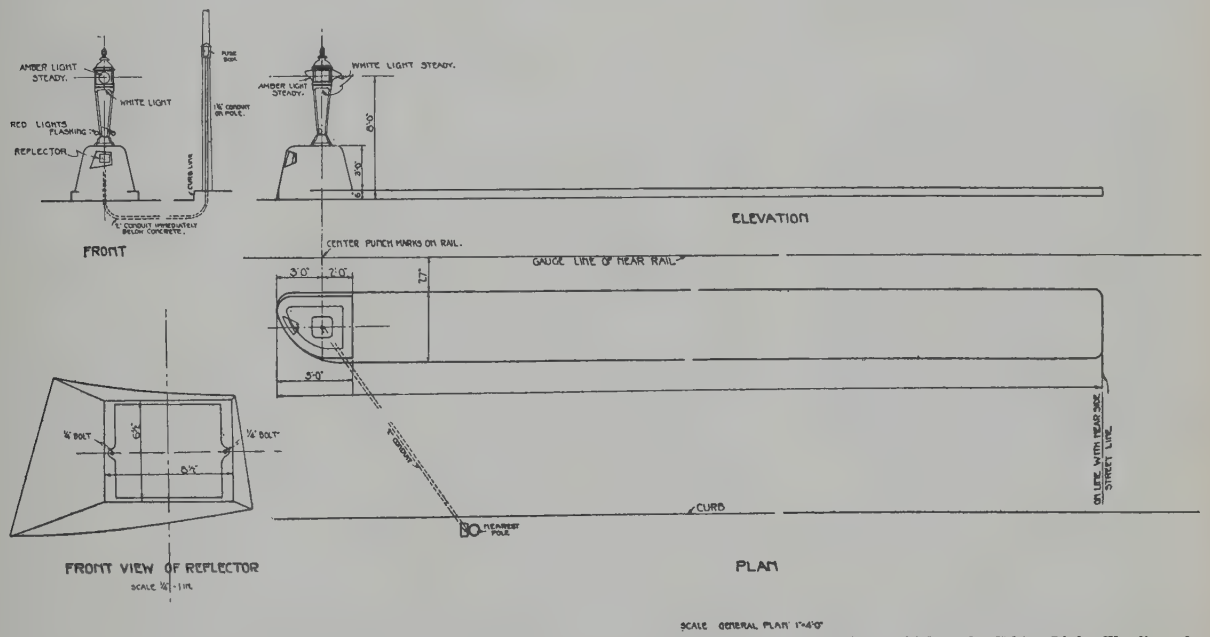
A RECENT contribution to the safety of pedestrians and street car passengers in Toronto, Ont., is the system of safety zones installed on St. Clair Ave., between Bathurst and Dufferin streets. The installation of beacons and concrete loading platforms has been a decided success, according to H. W. Tate, Assistant Manager of the Toronto Transportation Commission, who furnished the information here presented.

City, Commission Divide Cost.—In the latter part of 1928 the Toronto Transportation Commission reconstructed 1¼ miles of double track on St. Clair Ave. with its standard paved construction, where previously there had been open tracks and a boulevard strip. At this time an agreement was entered into by the city and the commission, providing for the construction of safety zones at the various car stops within the reconstructed section by the city, and furnishing and maintenance of lighting beacons by the commission. Under this arrangement 20 safety zones were constructed, the commission furnishing the city with the design of platform and buttress.

Design of Zones Based on Tests.—The original design called for an overall length of platform of 105 ft., to accommodate the standard length of train operated, but this dimension was shortened to 55 ft. by the city. A width of 4 ft. 6 in. and a height of 6 in. above the adjoining pavement were decided upon after a careful study of safety zone installations in a number of American cities. A distance of 2 ft. 3 in. from the near rail to the face of the platform gives proper clearance for the rolling stock operated by the commission.

Tests were made using a dummy platform, to insure that the clearance distance of 2 ft. 3 in. and the height of 6 in. above the pavement in no way interfered with the speed of loading and unloading and that no risks to passengers were introduced in these operations. The accompanying drawing shows the location and dimensions of the zones.

Construction of Beacon.—The beacon frame consists of a cast-aluminum housing, mounted on four tubular supports which are bolted to the concrete base. Three distinct optical units are provided in the beacon: one to attract the attention of oncoming traffic, one to light the loading platform and one to illuminate the concrete buttress at the base of the beacon pedestal. The aluminum housing contains these three units as well as a flashing motor. Doors are provided to give access to the units within. The height from the top of the concrete pedestal on which the beacon is mounted to the center of the lens is 4 ft. 6 in. At the base of the beacon are arranged two ruby globes, protected by guards and connected to the flashing motor. A red glass reflector is installed in the front of the concrete buttress as an additional safeguard in the event of a failure of the lighting supply.



New Safety Zone of the Toronto Transportation Commission. Notice the Amber Light Facing Oncoming Vehicles, the White Light Flooding the Loading Platform, the White Light Illuminating the Concrete Buttress and the Red Flashing Lights

Three-Purpose Optical System.—The optical units installed in the housing utilize two side faces and the bottom of the casting, and operate on a steady current.

For oncoming traffic there is provided a square condensing refraction amber lens having an illuminated area of 8x8 in. For lighting, a lamp of from 60 to 100-watt size is utilized. The lens is capable of distributing the light laterally over a wide angle. A visor is provided.

The system used for floodlighting the platform is placed on the opposite side of the beacon from the amber lens. A round lens of clear prismatic glass, 8⅜ in. in diameter, is employed. Illumination is provided by a 60-watt traffic signal lamp and a parabolic reflector. This entire system is rendered dustproof and weatherproof by means of rubber gaskets.

The concrete buttress supporting the beacon pedestal is illuminated through a lens in the bottom of the housing. This unit is essentially of the same arrangement as the unit used for floodlighting the platform, utilizing a square refraction round lens, gasketed into the bottom of the housing.

Beacon on Two Lighting Circuits.—The lighting units in the aluminum housing are on the street lighting circuit, while the two flashing lights mounted near the base of the pedestal

How the Beacon Appears to Oncoming Vehicles. The Ruby Globes Near the Base of the Pedestal Flash Continuously and the Red Glass Reflector in the Concrete Buttress Is an Additional Safeguard in the Event of a Failure of the Lighting Supply

are on a commercial circuit, allowing continuous operation. The flashing mechanism consists of a small 110-volt motor, with attached switch of the mercury tube type. The ruby globes flash once a second. The beacon is connected to the nearest curb pole by a 2-in. conduit carrying lead-covered cable, laid under the roadway. The beacons were supplied by the Canadian General Electric Co.

Cost of Installation and Maintenance.—The cost of each zone, complete with beacons, was approximately $700. It is believed, however, that future installations will not cost more than $600, as a number of development charges were included in the first cost. The cost of lighting will be about $1.50 per month and the cost of electrical maintenance $1.00 per month, making a monthly charge of $2.50 per zone.

Installation Pleases Public. — The zones have received many favorable comments and are freely used by pedestrians crossing from one side of the street to the other as well as by the car passengers. Vehicular traffic is allowed to proceed with caution past the zone while a car is loading and unloading and, as no curb parking is allowed opposite the zone, there is no doubt that vehicular traffic is speeded up.

Costs of Refuse Disposal by Various Methods

The cost of any particular method of refuse disposal varies greatly with the composition of the refuse and such local conditions as labor prices and the market for waste products. Some unit costs are given below as an indication of what has been done under various methods of disposal. These figures are reprinted from the advance proof sheets of a report of the Committee on Regional Plan of New York and Its Environs.

Feeding to Swine.—The operating cost of the Worcester, Massachusetts, hog farm was $2.65 per ton of garbage in 1917. The return from the sale of hogs was at the rate of $6.85 per ton of garbage, yielding a profit of $4.20 per ton. The city of Los Angeles, Cal., under its contract entered into in 1921, receives $0.60 per ton of garbage after loading on railroad cars.

Dumping at Sea.—The cost to New York City of dumping garbage at sea after loading at the waterfront dumps was about 15 ct. per cubic yard in 1924. There were 494 tows handled that year and the dumping ground was about 42 miles from the Battery during the summer months and several miles nearer during the winter.*

Garbage Reduction. — In Rochester, N. Y., 34,700 tons of garbage were treated during 1925 by the Cobwell reduction process, at a total cost, including operation and capital charges, of $9 per ton. By-products produced a revenue of $6 per ton, making a net cost of $3 per ton. Excluding capital charges, this amounted to $1.55 per ton net cost which it was hoped to reduce to $0.75 in 1926.†

The Cleveland, O., reduction plant, which averaged $1.70 per ton profit between 1915 and 1920, has been particularly successful. It shows the possibilities of this method under favorable circumstances and efficient operation. From 1921 to 1926 this plant operated at a loss, due to comparatively low prices received for grease and the high rate of wages paid. In 1926 this loss amounted to only 13 ct. per ton. These figures all include depreciation but no capital charges.

Incineration.—Statistics for 1925 for incinerating plants of Toronto, Can., indicated a total operating costs, less carrying charges, of $1.50 per ton, at a plant which handled about 50,000 tons annually of mixed garbage and rubbish, and $1.11 per ton at another plant handling about 63,000 tons.‡ An incinerator constructed in Buffalo, N. Y., in 1926, has been handling about 360 tons daily at a cost of $1.61 per ton.

To decrease the cost of incineration it is interesting to analyze the possibilities of the generation of steam. A modern high temperature destructor will furnish sufficient heat for the evaporation of 1 to 2 lb. of water per pound of refuse burned, depending upon the composition of the materials, in addition to any preheating of air required for the furnace operation. One ton of mixed garbage and rubbish per hour should generate 1,750 lb. of steam, or about 50 boiler horsepower. Assuming generator efficiency of 87 per cent, the developed horsepower would be 44.5 per hour or 33.2 kilowatts per hour. For a 200-ton plant on a yearly basis this would be 50,000 tons×33.2=1,660,000 kilowatt-hours. Electricity could be sold at approximately 1 ct. per kilowatt-hour or $16,600 per annum. If the electricity could be utilized for lighting and general purposes in New York City municipal buildings, it would save a present expense of approximately 5.40 ct. per kilowatt-hour, or $89,500.

The first basis, i. e., incineration without production of steam, would give an estimated 1925 unit cost of incineration of $2.36 per ton of garbage and rubbish. With production of steam on the basis outlined above, the unit cost of incineration would be $0.57 per ton of garbage and refuse.

Itemized costs have been computed based on labor charges obtained for certain incineration plants in New York City in 1925. For a 150-ton plant, handling 110 tons of refuse per day, the following labor was required:

1 Stationary engineer at $8.50 per diem	$ 8.50
6 Firemen at $6.50 per diem	39.00
3 Garbage Stokers at $5.50 per diem	16.50
2 Ash pickers at $5.00 per diem	10.00
2 Watchmen at $5.00 per diem	10.00
Total labor cost of disposal of 110 tons of refuse	$84.00
Labor cost of disposal per ton of refuse	.76

Similar figures for a 100-ton plant, handling 75 tons of refuse, showed a labor cost of $0.74 per ton of refuse. Taking into consideration all items of operation and maintenance, the following approximate subdivision of cost per ton was obtained:

Labor	$0.76
Other maintenance and operation costs	.06
Interest on investment at 6 per cent	.60
Amortization	.24
Depreciation	.24
Total cost per ton	$1.90

Beccari Method.—It has been estimated that the cost per ton under the Beccari method of disposal would be about $1.13. If a market should exist for the residual humus, this treatment might be expected to yield a profit.

The Maintenance of Small Water Meters

Important Features and Methods Used at Hartford

By H. W. GRISWOLD
Designing Engineer, Board of Water Commissioners, Hartford, Conn.

THE maintenance of its meters is always a live problem with the management of every water utility, and as the number of its meters and the cost of their maintenance increases, it becomes more and more important to so conduct the business that, on the one hand, too much revenue is not lost from out-of-repair meters, and that, on the other hand, too much is not spent on the upkeep of the meters themselves. Many factors must be considered in deciding upon a meter maintenance policy which will be balanced properly between these two extremes, which will meet the requirements of the public utility commission or other supervisory body, and will not produce an undue number of complaints from customers.

The First Item of Maintenance.—Meter maintenance really begins with the uncrating of the meter at the utility receiving room for the methods of handling as well as the type and kind of setting have considerable influence on the subsequent performance of the instrument. Rough handling and exposure to extremes of heat or cold are not good for any make of meter and are to be avoided always. Some utilities make a flow test on new meters before putting them into stock or into service. This serves not only as a check on the manufacturer's product but detects any meters that may have been damaged in transit or after delivery.

Setting Meters.—In setting meters two general methods are followed. One is to set the meter in the cellar of the building served as close to the point of entry of the service pipe as possible. The other is to set the meter in a box or vault at the street line. Which is the better form of setting depends on climatic conditions—how often the meter is to be read—against whom the cost of the meter setting is assessed—the length and kind of pipe serving the building—and the type of building. With either type of setting brass tail pieces or one of the numerous patented types of settings may be used. At Hartford, most of the settings are in the cellars of buildings, and all new meters are tested before being set.

Meter Costs at Hartford.—The costs of the different operations for the various sizes of meters are tabulated below.

The cost of the meter and all of the meter costs incurred up to and including the first setting are properly chargeable to capital outlay, so that from an accounting standpoint, maintenance costs may be said to start as the meter setting team drives away.

Many Ramifications of Maintenance Problem.—The problem of meter maintenance has a great many interesting ramifications and it is interlocked to a greater or less extent with practically all of the other activities of the utility, but, considered alone, the most efficient method of maintenance is the one which gives a minimum sum for the cost of keeping a meter in operating condition on each service, plus the value—at the established rates—of the water which passes through the meters unregistered. The maintenance cost item in turn is the sum of the costs of the various kinds of work that go to make up the job of meter maintenance, and of these operations, some must be performed regardless of cost, while others may be curtailed or extended as desired or as funds permit.

Repairing and Changing Meters.—A large part of the work and a part that must be carried on continually, is the changing and repairing of meters reported as "Down" or "Not Operating" by the meter reading or inspection force. The stoppage of the meter may be due to plugging with rust or some other foreign substance, to mechanical trouble in the meter or injury from freezing or from hot water. To remedy the trouble from any of these causes the meter must be removed from the service and taken to the shop for repairs. At Hartford a crew of two men with a light car are used for changing meters. For many years it was the custom to take off a meter, put a pipe nipple in its place, and when the meter had been repaired at the shop to make a second trip to put the same meter back on the service from which it had been taken. During the last year or two it has become the practice to take off a "down" meter and immediately to put on a new or repaired meter in its place from a small stock carried on the meter truck. This saves the second trip to the service and while it increases the clerical work somewhat, the net result has been a reduction in cost.

Shop Procedure.—In the shop, two methods of procedure seem to be in general use. In the smaller shops one man does the whole work of repairing and testing a meter. In the larger shops one man cleans and dissembles the meter; a second inspects it, decides what repair parts are needed and requisitions them from the stock room; a third man assembled the meter with the new parts and adjusts it; a fourth man tests it, and a fifth man paints it and makes it ready for the stock room or for setting. This procedure follows in general the standard factory method of splitting up a task into a number of operations of which the individual worker performs but one. Some shops replace gear trains and registers as units and have one or more men whose job it is to repair these parts only.

Stock Room Practice.—A stock of parts for each make of meter to be repaired at the shop must be carried, and the tendency is for this stock to grow unduly large if not carefully controlled. Where only a few meters of one make are in use, it is sometimes cheaper to carry no parts for them but to ship the meters of this make to be repaired back to the factory. The stock room practice usually follows that in use for the withdrawal of other material than meter parts from stores although some utilities do not keep a stock ledger for meter parts and do keep a ledger for main pipe and service pipe material. It is true of course that a meter stock consists of a great number of very small parts having a low price per unit and that the clerical work necessary to carry on a complete stores account for meter parts is a much larger percentage of the value of the stores than is the case with either main pipe or service pipe supplies.

Meter Testing.—In testing either new

Meter Costs for 1928 at Hartford, Conn.

Size—	⅝ in. Per Meter	¾ in. Per Meter	1 in. Per Meter	1½ in. Per Meter	2 in. Per Meter
Testing new meters	$ .29	$ .31	$ .56	$ .52	$ 4.25
Installing in buildings	3.37	3.84	4.84	8.41	9.30
Changing in buildings	1.35	1.50	1.38	3.36	8.11
Repairs and test (used meters)	4.45	5.20	7.81	12.30	18.40
Building Meters:					
Installing	3.95	.....	.....	.....	.....
Replace with permanent meter and repair and test building meter	10.04	.....	.....	.....	.....
Number of Meters Handled					
New meters tested	275	400	78	50	3
Installed (new) building	241	300	52	40	5
Box	21	25	6	.....	.....
Changed in buildings	753	745	187	25	21
Used meters repaired	914	843	213	31	30
Building meters	517	.....	.....	.....	.....

or repaired meters one of the several makes of meter testing machines is very generally used together with the necessary tanks and scales for determining accurately the quantity of water passed by the meter. A machine which tests one meter at a time usually suffices for a small shop but as soon as more than three or four are working on the repair of meters a machine that will test meters in groups of from five to eight is found to be more satisfactory.

Meter Records.—Meter records are an essential part of any successful scheme of meter maintenance, but the cost of these is apt to mount along with the stock room costs if not watched. Records, no matter how interesting, which are not summarized at frequent intervals nor used regularly in the conduct of the business should be viewed with a critical eye. No system can function without some form of work order, which is often made to serve as a report of the job when completed. All meter work must be reported in detail to the meter reading department in order that the meter readers' books and the consumers' ledger may be kept straight and up to date, for it is on these in the last analysis that the utility depends for its income—the most important thing in many ways in the whole business. Whether it pays to keep a record of the kind, number and size of meter on each service or to keep a history card for each meter on which is noted all its goings and comings, the amount of water it has passed to date, all the tests that have been made on it and the cost in detail of each operation, are questions which have as many different answers as there are utilities. These meter life histories are interesting to study, but from an operating standpoint it would hardly seem worth while to keep such close track of a $10 to $15 article unless such records would pay for themselves in pointing the way to economies in maintenance or in determining the most efficient make of meter to purchase. The latter use of the history is the one most often stressed, but it is doubtful if many meters are actually purchased on the strength of the records made by the early—and now obsolete—models of that make of meter.

Minor Meter Repairs.—There are certain repairs that can be made without removing the meter from the service. Chief among these are stuffing box leaks and the replacement of the register glass cover. By having the meter readers note the nature of the trouble in reporting a meter "down" it is possible to have these repairs in place taken care of by one man with a light car to take him from job to job, and thus a large part of the expense of taking off and replacing the meter is avoided.

Meter Reading. — The frequency of reading meters is a factor to be reckoned with in meter maintenance. The cost of reading meters for billing purposes alone is not properly a maintenance charge, but often meters are read one or more times between billing dates for the dual purpose of detecting "down" meters and of locating meters which show excessive consumption so that the owners of the property may be notified and may either take steps to stop the excessive use or waste or be prepared for an unusually large bill at the end of the period. The cost of these intermediate readings is in part at least chargeable to meter maintenance and if the interval between readings is short enough it will be unnecessary to make additional inspections of small meters in place. In Hartford the small meters are read every two months and the bills sent out every six months. Large meters are read and billed monthly. Interesting data on the current practice regarding meter readers and meter reading in other southern New England cities are shown in the tabulation.

Data on Meter Readers and Meter Reading in Southern New England Cities

Number of Meters	How Often Read	No. of Readers	Hours Worked Week	Rate of Pay	Meters Read per Man	Other Work Done

41,276	3 mo	10	44	$24-$30	85	Inspect
96,460	big 1 mo sml 3 mo	31	38	$25-34	49	None

It seems to be generally conceded that meters, even though they are apparently operating perfectly, should be removed, tested and repaired at intervals in order to keep them within reasonable limits of accuracy. In some states—Connecticut among them—this interval is determined by a ruling of the Public Utilities Commission or similar regulatory body, and varies from about five to ten years. The lower figure is for Connecticut and the higher for New Jersey. In some cases the maximum quantity of water that shall be passed by a meter between regular tests as well as the time interval between tests is specified. For any utility not covered by a definite ruling regarding regular tests, the proper interval between tests could be determined from the costs of changing and repairing a meter, the rate charged for water, and data on the average performance of the makes of meters in use in the community over a period of years. The first two items are known or can be readily ascertained but even where meter histories are kept it is not easy to construct a performance curve that will be truly representative. Factory tests show that a meter may register on a 1/32-in. stream after passing a million cubic feet of water. In general, however, it may be said that meters do not register more water than passes through them—consumers to the contrary notwithstanding—and that the longer meters run the less accurate they are—the decrease in accuracy being a function both of the time in service and of the quantity of water passed.

Conclusion.—In conclusion, and as a summary, it may be said that the five factors which have the most effect on the cost and efficiency of small meter maintenance are:

1—Frequent inspection of meters in service to detect those not registering and those over-registering.

2—The prompt removal and replacement of "down" meters with a minimum of lost motion.

3—The testing of all meters at regular intervals.

4—The application of efficient factory methods to the repair shop and the testing bench.

5—Close control over records and stock so that there will be enough—but not too much.

Acknowledgment.—The foregoing is an abstract of a paper presented April 10 at a spring meeting of the New England Water Works Association.

Minnesota Water Works Men Meet in June.—The next meeting of the Minnesota Section of the American Water Works Association is to be held jointly with the Minnesota League of Municipalities, June 12th to 14th, 1929, inclusive, at Austin, Minn. Secretary R. M. Finch, Wallace & Tiernan Co., 240 South 4th St., Minneapolis, Minn.

How to Secure Better Bituminous Macadam

The Importance of Watching Details in the Progress of the Work

By WILLIAM J. DOUGHERTY
Secretary-Engineer, Park Commission, Portland, Me.

IT may be of some interest to those who are engaged in building bituminous macadam, or who may, in the future, have this class of work to do, to offer some comment bearing on this type of construction which we are reasonably sure to have to construct in New England, at least, for some time to come. There is probably not one of the present accepted standard types of improved surfacing which has been more abused in construction, and which has varied so much in the degree of satisfaction attained as has this bituminous type. We can most certainly place a great deal of the trouble with, or the apparent shortcomings of this type of pavement, to that real enemy to good construction, the personal element or equation, if you like.

While the writer realizes full well that bituminous penetration construction cannot take it splace side by side on the economic scale with some of the really heavy duty pavements, such as reinforced concrete, sheet asphalt on concrete base and the stone block types, yet there is very much that can be offered to show that penetration macadam has an important role to fill in the development of any comprehensive highway system in New England and many times elsewhere.

Salvaging Old Roads. — The wisdom of salvaging many of the worn-out macadam roads and many times the seasoned and treated gravel roads which are the results of progressive road building steps and to make these serve as foundations for bituminous pavements has been stressed repeatedly in highway writings. It is this very factor of seasoned depth of good foundation material that should make us alert to the economy of surfacing the road with bituminous pavement. Penetration construction appears to be the recognized type for usage with foundations as above described. We should be very reluctant to "scrap" a very valuable base road, if there is possibility of restoring it and making it conform to the grades and contours of the new pavement.

The Personal Item.—The writer has at times noted a marked indifference on the part of some officials, charged with highway work, to put real heart into bituminous penetration construction to get all there is of value into the pavement and this when it is found that neither the traffic to be served nor the funds at hand warrant the selection of a more rigid and more expensive type. Mention of expense prompts me to say that under conditions often met in practice, bituminous penetration can cost considerably more than concrete pavement if you have to prepare an adequate base. Due to the necessity of deep base construction required ordinarily for bituminous macadam, by comparison to reduced thicknesses of bases (with just as much effectiveness) required for concrete pavements, it is many times wiser to accept the reinforced concrete pavement at a higher cost per square yard than to attempt a thoroughly new and adequate build-up for bituminous macadam. In short, it is when our predecessors in highway construction have bequeathed us something of real value that we should be alert to utilize to the very best advantage, former expenditures in base course construction.

To my way of thinking and from actual observation there are altogether too many so-called road builders entrusted to build this, as well as other types, who, either from a lack of knowledge of the details making for good construction, or else, from a standpoint of discounting in advance the merit of the pavement, fail to get real value received for the expenditures made.

Relative Importance of Bituminous Macadam.—As to the relative importance of bituminous macadam, it may be of interest to note that an article on "The Trend of Highway Design," May, 1927, Roads and Streets (the matter compiled by engineers of the Office of Public Roads) shows that bituminous macadam increased its popularity over previous years and it is presumed here that since the time of this article the popularity of this type has not waned.

View of Baxter Boulevard, Portland, Me., Showing Asphaltic Macadam Finished August, 1927 Start of Landscape Treatment Shown on Side. Slope to Sidewalk Will Be Planted with Flowering Shrubs

Of all Federal Aid road mileage completed by types to June 30th, 1926, bituminous macadam comprised 5.6 per cent and cement concrete pavements 20.3 per cent of the total mileage, but of the one year ending June 30th, 1926, bituminous macadam was 7.4 per cent of the mileage done while concrete was 24 per cent. This demonstrates that this type is still "in the picture," and if we are to do it, let's do it as well as we are able to do it.

The writer wishes to emphasize here that in his opinion bituminous macadam is much more difficult to construct in a thoroughly satisfactory manner than many of the other types of pavement in present use. Cement concrete pavements of today are constructed under most meticulous specifications for materials and methods and under careful field control and with the mechanical equipment at hand for uniform and speedy results and the exactitude required to have the surface conform by templates and finishing machines to the required even surface there is much less of the individual workman's skill re-

quired. With the recognized mixed types of asphaltic construction we have the laboratory control and the advantage of highly standardized gradings of aggregates, analyses of bitumen and many other helpful matters, but with bituminous macadam it is not practicable to control the construction by such clearly defined methods and, written specifications to the contrary, officials in charge of bituminous penetration construction many times find themselves somewhat at the mercy of the contractor for this kind of construction and his ability to value details, which add considerably to the merits of this type of construction.

View Showing 1928 Asphalt Macadam Construction at Hanson's Creek, Baxter Boulevard. A 48 Ft. Width of Newly Paved Surface. Note Coarse Texture of Finished Surface in Foreground, Also Slight Overlapping of Seal Application in Foreground and Small "Fat" Spots in Right Middle. These Are Slight Defects to Guard Against in Construction of This Kind

The Importance of Rolling.—For instance it is not general practice to "true" a surface of macadam pavement with a straight edge (although this has been tried in some sections of the country with varying success) and we must admit that surface irregularities of any consequence are incipient causes of failures in a pavement. Nor is it very practical to say, in a quantitative manner, in advance, the extent to which stone shall be rolled before penetration application, after penetration, and finally after seal coat. The two points mentioned may appear relatively unimportant to some, but to the writer, who has had considerable experience in this class of construction the matter of intelligent and adequate rolling is all important, and many times the lack of thorough compaction will spell disaster to the road under traffic. The quality of stone in the construction of bituminous pavement, being variable within accepted limits of wear tests, it remains to the engineer or inspector in charge to get as much compaction and interlocking of particles of the stone course before penetration as possible without serious crushing of the stone particles, with consequent choking of the voids and prevention of thorough penetration of bituminous material throughout the thickness of the wearing course.

Of course, stone acceptable for the wearing course should stand a reasonable amount of rolling, but many times we run into stone that varies on the work and if it is a case of withholding a measure of rolling, so as to insure thorough penetration of bituminous material, this should be done by all means. It is particularly after penetration that the writer would insist on most thorough rolling. It is extremely important that the operator roll and roll and then roll some more, and to do so, if possible, in the warmest part of the day. Let it be said that it is not always easy to get the present day road roller operator into the spirit of rolling such as described.

You will think that this is too much space to give to this one detail of this comment, but the writer has observed this point of construction to be a rather critical one in the success of bituminous macadam. At the point of surface irregularities it is quite obvious to most road builders that bumps and hollows cause trouble either by weaknesses arising out of impact of traffic or from freezing and thawing stresses to say nothing of the discomfort of riding. And since generally speaking we do not grade by template the coarse stone that is presently being used in this type of pavement, you can readily appreciate the care involved in getting a true and even road shape by the use of mechanical stone spreaders and some hand grading.

It facilitates greatly the matter of surface grading, as well as adding something very valuable to the construction, to have the base course of stone graded as nearly as practicable, parallel and uniformly below the finished surface and to have the base course finally compacted and tightened by the method of void filling by dry rolling (if possible) into the base all the screenings or sand (screenings preferred under dry weather conditions) that can be put in and yet leave a "toothy" surface to this course.

Thickness of Wearing Course.—As to the thickness of the "wearing" course of macadam, 3 in. seems to be the popular thickness and with the present practice of using stone passing a 2½ in. ring it would not seem sensible to have less than this thickness. While 5 in. is a popular thickness for base course, under exceptional conditions for foundations it would seem sensible to cut down on this thickness of base course, in accordance with conditions as you may find them; but one thing must be kept in mind and that is that any macadam surface requires considerable depth of base course, or foundations material to distribute the surface pressure over a good area of subgrade.

Application of Bituminous Material.—To the writer there is always a very intimate relation between depth of penetration course, size of stone used, and the amount of bituminous material applied. We are very cautious to control the amount of bitumen by weight when handling the fine and coarse types of asphaltic concrete. And, although we rely a great deal for stability on the interlocking particles of stone in bituminous macadam, we should have a quantity of bituminous material sufficient to cover the surfaces of the particles. If it is determined by practice and investigation that a certain specified amount of bituminous material will accomplish this for a given depth and grading of stone, we should adhere to this quantity for the conditions determined and not depart from this by way of being careless of the depth of stone. During 1927 and 1928 construction, the writer has had excellent results using approximately 1.75 gal, for the first application and 0.75 gal. for seal coat where the nominal depth of course was 3 in. and the stone trap rock of commerical 2 in. size (passing 2½ in. and retained on 1½ in). These rates conform to good practice and are closely watched by the writer during construction.

In connection with the use of bituminous material, probably the outstanding offender is the one who uses a surplus of material with resultant "fat" spots. The writer has frequently observed men lacking experience in the use of bituminous materials, who naturally believe that a good "dose" of the "black stuff" is good insurance and work accordingly. This getting out of hand should not occur on important

road work as this item is pretty carefully controlled, but you can observe it in small repair work or very small projects where experience is not the guiding hand.

Grading and Application of Keystone. —There is one detail of construction of bituminous macadam which has occurred to the writer to deserve perhaps a little more mention that it usually gets. This is the matter of grading and application of the so-called "keystone" following the first application of bituminous material. Up to a short time ago, at least, there appeared to be two "schools" in New England when it came to this detail of contruction. One prominent state was using the same sized stone for "keystone" and final seal coat topping, this being a trap product passing ⅝ in. and retained on ¼ in. (so-called "pea stone"). The other school used for "keystone" a product passing 1 in. and retained on ⅝ in. and for seal coat "pea stone" size passing ⅝ in. and retained on ¼ in. Both states apparently secure good results, although in the former case the mosaic of the larger road stones is much more clearly defined, while in the case of the use of the ¾ in. stone after penetration followed by the use of the "pea stone" for seal, the mosaic appearance is obscured and the surface is for some time after construction somewhat rougher in texture. The writer has had very satisfactory results with the use of the two sizes of stone in connection with the bituminous applications and it would appear to be more in keeping with a desire to get density and stability by using more graded stone materials. Moreover, there is apt to be dust troubles when the smaller size stone is applied to first applications. Clear stone is much to be preferred even if this product does seem a little "coarse" and has an apparent tendency to break the initial bond of stones in the wearing course.

The writer has found it well worth the trouble and small expense involved to take care to broom the chips about after rolling with a view to filling surface voids uniformly, and after removal of surplus chips to roll lightly again. This rolling seems to give a better appearance to the road surface when finally finished with the seal coat application.

In conclusion, much of the foregoing comment will seem elemental to those who have made a close study of the essentials to good construction of bituminous macadam construction, but the purpose of this article will be served if it will help to impress the less experienced with the importance of watching details in the progress of this type of road construction. The matter contained herein has been discussed without much thought to taking the several points of construction as they are met in the order of work.

Engineers in Public Life

A recent canvas by the American Engineering Council disclosed a number of engineers holding responsible positions in the political life of the nation. The study covers a canvas of governors of all states and members of the senate and house of representatives.

Beside the engineer in the chief executive's chair, President Herbert Hoover, those listed are divided into three classes. First, those who are or were at the time of their election to public office, professional engineers both by training and experience. The second group comprises those who have been engaged in work which is essentially engineering and which requires the engineering mode of thinking and method of approach. The third group is of those who received their basic training and education in engineering—those who received a bachelor of sicence degree in an engineering school, but have subsequently taken up other fields of activity.

Engineer Governors. — The governors who are professional engineers are: Clayton D. Buck, of Delaware; George H. Dern, of Utah; F. C. Emerson, of Wyoming; Morgan F. Larson, of New Jersey, and George A. Parks, of Alaska.

Governor John H. Trumbull of Connecticut has received no engineering degree, but has been engaged in the manufacture of electrical machinery, having been president of the Trumbull Electric & Manufacturing Co., chairman of the board of the Colonial Air Transport Co., director of the Hartford Steam Boiler Inspection Co., and similar enterprises.

Governor Bibbs Graves of Alabama, although a lawyer, received his first degree as a bachelor of civil engineering, University of Alabama.

Governor O. M. Gardner of North Carolina, was a student at the State College of Agriculture and Engineering and received a B. S. degree from the University of North Carolina.

Governor Harry S. Leslie of Indiana received the degree of B. S. from University of Purdue.

Two recent and well-known ex-governors are professional engineers: James G. Scrugham of Nevada and James Hartness of Vermont, past president of American Engineering Council.

From this survey there would seem to be a decidedly increasing tendency of the public to trust men of engineering training with public office. Iu 1920 there were but two governors of states who could be placed in one of the three classes above. In 1910 there were likewise only two.

Engineer Senators.—In the U. S. senate of the 70th congress there were five men with engineering training and experience. These were: Vice-President Charles Dawes, Senator R. B. Howell of Nebraska, Senator H. W. Keyes of New Hampshire, Senator Tasker L. Oddie of Nevada, and Senator Millard E. Tydings of Maryland.

A decided increase in the number of men who have engineering training and experience is shown. In 1920 the senate had but two men who could be placed in these classifications, and in 1910 there were three.

Engineer Congressmen. — The house of representatives in 1910 contained three professional engineers and three members with engineering experience, also three with B. S. degrees. The house of representatives in 1920 contained two men with engineering experience and thirteen who had received B. S. degrees. The house of representatives of the 70th congress, 1929, contained a total of 21 members with engineering training or experience.

The five members of the house of representatives, 70th congress, who may be classed as professional engineers, are: L. W. Douglass of Arizona, H. L. Englebright of California, S. S. Arentz of Nevada, Ernest R. Ackerman of New Jersey, and J. T. Deal of Virginia. The following have had some engineering experience: Paul J. Moore of New Jersey, Wm. L. Carss of Minnesota, John McSweeney of Ohio, Franklin Menges of Pennsylvania, and Louis Monast of Rhode Island. The members who have had training in some engineering institution and in most cases have received B. S. degrees from an engineering college are: R. A. Green of Florida, L. J. Dickinson of Iowa, W. B. Gregory of Kentucky, David Kincheloo of Kentucky, W. P. Martin of Louisiana, W. P. Colo of Maryland, Jess Bushby of Mississippi, F. M. Hale of New Hampshire, A. J. Griffin of New York, George C. Peery of Virginia and F. T. England of West Virginia.

Training City Managers

The report of the Committee on Curricula of the International City Managers' Association, according to the Toledo City Journal, indicates that there are now five universities offering courses designed especially for the training of city managers, namely, Michigan, Syracuse, California, Stanford, and the Agricultural and Mechanical College of Texas. There are several others offering courses which might be considered suitable for the training of city managers, but which have never been organized as such. These include Chicago, Cincinnati, Harvard, Illinois, Kansas, Ohio, North Carolina, Wisconsin, and the National Institute of Public Administration. A number of others such as Northwestern University, Western Reserve and Toledo University, which the committee might well have considered in its report, while giving a great deal of municipal government make no special claim to training city managers.

Water Supply Costs

Unit Costs of Collecting and Distributing Systems

SOME interesting figures indicating the expenditures required for supplying water to large population centers such as the New York region are given in the report "Physical Conditions and Public Service" of the Metropolitan New York region of the Committee on Regional Plan of New York and Its Environs. The report was prepared by Harold M. Lewis, Theodore T. McCrosky and Raymond A. O'Hara of the Engineering Staff, Regional Plan, Hastings H. Hart of the Russell Sage Foundation and Henry C. Wright, Hospital Consultant. The matter following relating to unit water supply costs is taken from advance page proofs of the report.

Collecting Systems.—The Catskill System of the City of New York was constructed between 1907 and 1926, and includes Ashokan, Schoharie, Kensico, Hillview and Silver Lake Reservoirs. Its total cost was about $188,000,000 and it provides 600 million gallons daily. This gives a unit cost of approximately $313,000 per million gallons daily.

The cost of the Ridgewood System on Long Island, which was started in 1850, was, up to 1906, about $16,900,000 including reservoirs.[1] This furnishes 127 million gallons daily and the unit cost amounts to $133,000 per million gallons daily.

The Joint Board authorized by the Massachusetts Legislature to report on the water supply of the Boston Metropolitan District estimated, in 1922, that a new system to supply 202 million gallons daily would cost $59,946,540 or about $300,000 per million gallons daily.

Hazen, Whipple & Fuller, in their report to the Board of Conservation and Development of the State of New Jersey, in 1922,[2] estimated that new supplies would cost from $173,000[3] to $417,000 per million gallons daily. The North Jersey District Water Supply Commission estimated, in 1926, that the unit cost of the 100 million gallons daily of the Wanaque project would be $204,000 and that the complete development of the Chimney Rock project to furnish 750 million gallons daily would be $229,000.[4]

The Board of Water Supply of New York City estimated that proposed new supplies in Putnam, Dutchess, Columbia and Rensselaer Counties, totaling 422 million gallons daily, would cost $575,000 per million gallons daily, while an initial development of 204 million gallons daily from the same sources would have a unit cost of $736,000.[5] The New York City project for developing new sources in the watersheds of the Delaware River and Rondout Creek has been estimated to have a unit cost of $505,000 for a yield of 510 to 540 million gallons daily.[6]

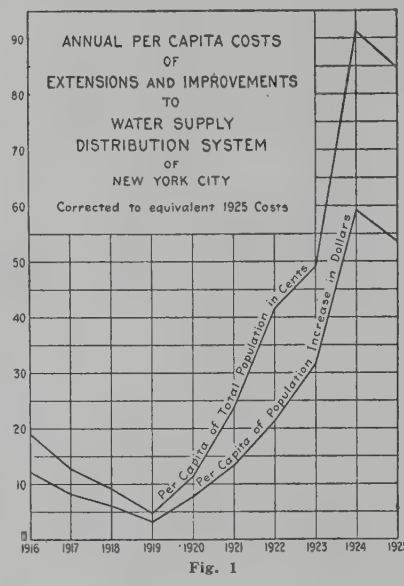

Fig. 1

It is probable that additional supplies for that part of the Region east of the Hudson River will cost from 50 per cent to 100 per cent more per million gallons daily than did the Catskill supply, or $450,000 to $600,000.

It can be assumed that the territory west of the Hudson River can be supplied more economically due to its readier access to sources of supply, or at costs per million gallons daily of approximately $250,000 to $450,000.

The per capita cost of developing a water supply (exclusive of distribution system) now varies from $30 to $60. An average figure would be about $50 per capita.

The consumption per capita in New York City in 1925 was about 140 gal. per day. An average figure for estimating future demands in the Region would be about 150 gal. per capita per day.

Distribution Systems.—The distribution system for the Ridgewood supply in Brooklyn cost, up to 1906, about $13,197,000. By 1926, New York City was spending about $8,000,000 per year on its distribution system. This was high as it included some deferred costs due to lack of funds during the war period. Such expenditures were considerably less than normal for about ten years after the opening of the Catskill System as the main aqueduct, which passes under the city, took the place of many new trunk distribution lines that would otherwise have been necessary. In March, 1927, plans for an auxiliary deep-level aqueduct for Catskill water estimated to cost $67,249,000 were approved by the New York City authorities. This will run from Hillview Reservoir in Yonkers across the Bronx, under the East River, and across Queens and Brooklyn, and will be 17 ft. in diameter for the greater part of its length. It was estimated that it would take about seven years to complete it.

The normal figure for extensions to the distribution system would be in the neighborhood of $4,000,000 per year. The maintenance charges upon the distribution system are approximately $1,250,000 per year. The average annual increase in water supply requirements in New York City from 1915 to 1925 was about 32 million gallons per day.

A factor for use in estimating future costs of extensions and improvements to the distribution system was obtained by taking the Department of Water Supply records for disbursements on the distribution system from 1916 to 1925, correcting these for changes in the cost index and reducing them to costs per capita. The results, shown in Fig. 1, give a curve which may be applied to future population.

The cost per capita, reduced to 1925 money values, has increased steadily from 1919, when it was 5 ct., to 1924, when the figure was about 91 ct., and in 1925 it dropped to 85 ct. The cause of this rise is explained above. As such expenditures are primarily for the use of the additional population, a curve has also been added for per capita expenditure on the basis of the annual population increase. This is seen to have varied from three to $59 and to have been about $53 in 1925.

Training Schools for New York State Municipal Employees.—A comprehensive program for the training of all groups of municipal officials and employees was adopted at a recent meeting of the Advisory Committee of the Conference of Mayors and Other Municipal Officials of the State of New York, according to the City Record, Boston. Ten years will be required for putting into effect the complete schedule, which calls for the establishment of training facilities for health, fire, charities and financial officials, civil service employees, water bureau superintendents, purchasing agents, city and village clerks, park officials and assessors. The conference has plans already under way for the training schools for fire department and charities department employees similar to those now being organized for police training, and the training of health officers is being taken care of by the State Health Department.

[1] Long Island Sources—Report by Board of Water Supply, 1912, Table 20, page 300.

[2] Report on Water Resources of the State and Their Development, January 28, 1922, page 63.

[3] This was based on a complete development of the proposed Long Hill System to provide 750 million gallons daily. The earlier steps in this system would call for much higher unit costs.

The Identification and the Control of Algae

How to Identify Various Species and Control Them

By L. B. MANGUN

Chemist in Charge, Department of Water, Light and Power, Kansas City, Kan.

CONTROL of algae is, of course, the all-important objective, and the average water works man, usually very practical and very busy too, is primarily interested only in what contributes directly to that end. If, as in the case of one class of microscopic plant life, bacteria, there were some of the algae which caused disease if swallowed by humans, among many others which were harmless, then he would have had the same reason to be concerned about the identification of the harmful ones that he has had for differentiating Bact. coli. And if that were true there would undoubtedly have been some well-defined standards set up for his guidance with respect to them. But, as is doubtless understood by every one, algae in themselves are believed to have no sanitary significance. Rather, their presence in a water supply is usually thought of as objectionable for aesthetic reasons, because they impart color and cloudiness to the water. All forms of algae are obnoxious from the standpoint of appearance, but further than this, most of them cause the water to have a disagreeable taste and odor, and this fact does have an indirect sanitary significance. The public, not knowing the cause of the taste odor and ignorant of its harmlessness, will always imagine the worst, and in an effort to avoid fancied dangers many people will resort to the use of other supplies which may be available, such as wells and springs, which may indeed be unsafe bacteriologically.

Identification of Assistance.—Although identification of algae is not absolutely essential to control, it is nevertheless often of considerable assistance, just as complete knowledge about any process is more desirable than ignorance on the part of the person in charge of it. This information about the algae species with which one is dealing is valuable for record purposes and comparative study. It makes possible an understanding of their genesis, their life history, and perhaps a forecast concerning the probable future course and final results of their development. Incidentally, where the operator has the time and inclination he will find it an exceedingly fascinating study. The simplicity of the most essential laboratory manipulations in the process of identifying at least some of the more common forms is such that almost anyone, regardless of previous training, may do enough to become interested, if one has a little equipment with which to do the work. This need not be extensive, but a good compound microscope is essential. If a microscope is already at hand, the little other necessary apparatus is relatively simple and inexpensive.

Quantitative Estimation of Plankton.—Before taking up a discussion of identification of algae it would be well to give attention to the quantitative estimation of plankton, because it is probably of even more practical importance for control purposes than the determination of the identity of the organisms. By plankton is meant all microscopic, or near microscopic, aquatic life, other than bacteria, and excepting plants which are attached to the shore or basin walls. Many forms of tiny plants and animals suspended in or floating upon the surface of the water are collectively known as plankton. If the operator is to keep an open reservoir situation well in hand it will be of great assistance to him to keep a watch on the number of these plankton organisms present. Whenever he observes a sudden tendency for them to increase it will serve as a warning to him to apply treatment before their multiplication reaches the nuisance stage and be the cause of complaint on the part of consumers. If an initial increase in numbers is checked by treatment at once there will also be less of the objectionable after-effects due to the presence of large numbers of dead organisms in the water.

For the purpose of enumeration, in addition to the microscope, a counting cell, and ocular and stage micrometers are necessary. A Sedgwick-Rafter filter is sometimes a valuable assistance, though not often necessary for control purposes in settling basins and distribution reservoirs. This apparatus may be purchased from any of the laboratory supply houses. The counting cell is filled by means of a pipette with water from the sample as taken, or in case the organisms are few, with a concentrated sample from the Sedgwick-Rafter filter. After counting the organisms in a dozen or more squares and determining the average, the appropriate factors are used to find the number per cubic centimeter.

Standard Units.—It is sometimes more meaningful to state the quantity of the organisms in "standard units," which is a measurement in terms of volume rather than a mere count of numbers, because a large number of small organisms, such as the Protococcus forms, would affect the appearance of the water far less than a much smaller number of a large species, like Volvox. The area of the smallest square shown by the ocular micrometer is 400 square microns, which is equal to one standard unit. One Volvox per cubic centimeter would be equivalent to about 490 standard units, while 25,000 of some of the Protococcus species would be required to give the same number of standard units. The estimation in terms of standard units is preferable when the name of the organism is unknown, but if the organism is identified and its name given, then number alone has a more definite meaning. However, if there is a mixture of organisms the use of the standard unit is most desirable, and it is obligatory in making any definite quantitative statement concerning debris—broken-down amorphous masses from the disintegrated bodies of dead organisms.

Before the observer will have finished with the counting, if he is endowed with only the average amount of curiosity which characterizes the human species, he will have become interested in knowing something more about the tiny creatures with which he is dealing. He will want to see them better, and, as the low power of the microscope has probably been used for the counting, he will not be long in reaching for the 4 m. m. objective to get a more enlarged view. Next the question involuntarily comes to him, "What is it?" He may not be a botanist or a zoologist, but he feels much the same as he does when visiting the zoo or the circus, where he wants to see the names of the strange animals placarded on the cages, and he experiences a sense of irritation and dissatisfaction if the names are not there. He also would like to know from what country they come and he would be interested in any bits of information about their habits and manner of living. Now, there is probably as much incentive to satisfy that natural curiosity concerning the names of the algae as there is because it will enable him to say whether or not the organism will impart a taste to the water, what that taste will be like, and how much of a dose of blue vitriol will be required to kill it. This brings us to the subject of identification.

Identification of Algae.—If the water works operator has never studied botany or zoology at all, or extensively enough to have obtained some knowledge about the lowest forms of life, it would be very desirable for him to get an elementary treatise on biology from the

library. In the event that he has had an unpleasant and perhaps unsuccessful encounter with algae in his water supply, and especially after he has seen some of them under the microscope, he will find that, having made that sort of an approach to the subject, the book will be of the most absorbing interest to him. He will be amazed at the wonders he finds in this, to him, new world which he has discovered.

It is not intended to intimate, however that our amateur student of biology must master the details of structure and the intricacies of classification—species, genera, orders, etc.—before he can hope to identify any of the organisms found in plankton. He should procure a book containing descriptions and colored plates of the species most commonly met, such as Whipple's Microscopy of Drinking Water or the more complete Ward and Whipple's Fresh-water Biology, both published by John Wiley & Sons, New York. Though he may not be able to use the keys contained in these books at all systematically, even the most haphazard search in them will often reveal unmistakably the identity of the species, or at least the genus, he has met, unless it should perchance be an uncommon one, which rarely happens. As a matter of actual fact it is usually the genera and not the species one hears about. For example, the presence of Anabaena is reported in a certain reservoir. New, there are several kinds of Anabaena, but for practical purposes, the difference between them is not worth considering. The identical species one has under the microscope may not be shown in either of the books referred to above, but its resemblance to the one pictured will be such that one will know it to be a species of Anabaena. He will find, after locating it in this manner, that it belongs to the blue-greens, that it will impart a grassy or moldy odor to the water, and that a concentration of 0.1 p. p. m. of blue vitriol will be required to destroy it. Thus, while there are more than 1200 known species of blue-green algae, the number of genera are much smaller, and the most common among them are illustrated in these books. Whipple's book contains excellent colored plates showing nineteen species of the Cyanophyceae, or blue-greens, forty-eight of the Chlorophyceae, or greens, and fifty-one of the Diatoms. Then there are representatives of the microscopic aquatic animals, principally Protozoa. The Protozoa are the most important class of the non-algae plankton, of which forty-three species are illustrated.

What Algae Are.—It would perhaps be desirable for the orientation of beginners to explain briefly what algae are, and, since the authors referred to do not do so, to say a few words concerning the place they occupy in the world of living things. The term Algae is often used very loosely, sometimes almost synonymously with the word plankton, which includes both plants and animals. Algae are plants, and constitute one of the three groups of plants called Thallophytes, the name given to those having no root, true stem, leaves, flowers, or seeds. The other two Thallophyte groups are bacteria and fungi, which differ from algae in that they have no chlorophyll. The algae are characterized by the presence of chlorophyll, but the green color of chlorophyll is masked in many of them by yellow, brown, red, or blue coloring substances. The fresh-water algae are divided into three classes, the diatoms, which are yellowish-brown, the blue-greens, and the greens. The last group are algae in the strictest sense of the term, though botanically algae include the diatoms and the blue-greens also. The brown and red orders of the algae are mostly marine, and are therefore not encountered in our water supplies. Diatoms are one-celled, usually free-swimming, and are the most numerous order of the algae, more than 12,000 species being known. The greens and blue-greens are either simple unicellular or filamentous, the latter free-floating or attached. About 1,200 species of the blue-greens and 5,000 greens have been identified. In addition to the algae the plankton plant-life includes a few of the non-chlorophyll Thallophytes, yeasts and molds, which belong to the fungi.

The representatives of the animal kingdom found among the micro-organisms inhabiting fresh water are the Protozoa, which are unicellular organisms, the lowest form of animal life. Then there are other minute animals which are multicellular, the Rotifera, or wheel-animalcules, the Crustacea, or water insects, and the Bryozoa and Sponges, both of which are animal groups, though they are fixed and plant-like in appearance.

This animal life feeds upon the vegetable portion of the plankton, Hence. if the algae are not allowed to flourish these organisms are held in check through deprivation of their food supply. That is fortunate, because the algae are more susceptible of the poisoning action of the treating agencies than are most of the animal groups.

Attempts have been made to control algae in uncovered reservoirs by stocking them with fish which feed upon the algae, upon the assumption that fish are a less objectionable form of life in a water supply than algae. This plan has difficulties. If the basin is overstocked there will not be sufficient food and some of the fish may die. Dead fish are even less desirable in a finished water than live ones. On the other hand, if the fish are too few they will not consume all of the algae, especially at times when it is growing most rapidly, and it is very difficult under these conditions to treat the water chemically to destroy the excess algae without killing the fish wholesale.

Methods of Control.—The most common method of control has been by the application of algaecides to the water. Until quite recently blue vitriol was used almost exclusively. It gave very satisfactory results in large impounding reservoirs, and it is still the favorite treatment in them. Under those conditions dosages low enough to be harmless to fish life are usually effective. But blue vitriol never gave correspondingly satisfactory results in settling basins and storage reservoirs, and during the past two or three years chlorine has been rapidly displacing it. The continuous change of water in these reservoirs makes frequent treatment necessary. Where there is a constant flow of water, as in settling basins, continuous treatment of the influent is desirable, and that should probably be considered a misuse of blue vitriol because of the possible cumulative effect of copper. But the generally turbid character of the surface supplies of Kansas protects the water as received from carrying excessive plankton growths, such as would give trouble from tastes or clogging of filters. Algae, in common with all chlorophyll producing plants, require sunlight, therefore they do not multiply in water not clear enough to allow the sun's rays to penetrate beneath the surface. In the event that there is sufficient retention of the settled water in the finishing basins, there would be an increase of algae in them proportional to the clarity of the water and the length of the period. But retention is probably not of sufficient duration in many cases to give serious trouble, so that, while prechlorination, i. e., chlorination of the raw water, is being employed in some instances and has given admirable results with respect to its algaecidal action, these have been incidental to the primary objective of this chlorine treatment, which has been to reduce the bacterial load upon the filters. Where clear water is constantly moving through an open basin, soon to be delivered to the filters and thence into the underground distribution system, there is slight opportunity for plankton growth. Therefore, the free-floating forms do not become abundant. But the filamentous types which cling to the weirs and walls do grow very well under those conditions, and the growth is most luxuriant where the movement of the water is most rapid. Prechlorination has proved to be decidedly effective in keeping down these clinging forms, thereby making possible the maintenance of clean basin walls without the necessity of frequent removal by mechanical means, such as scraping, or the lowering of the water and spraying the walls with blue vitriol solution to kill them.

Prechlorination.—A maximum chlorine dosage of about 1 p. p. m. in summer and 0.25 p. p. m. in winter has been sufficient to produce the above results at the Kansas City purification plant. Chlorine has been used as an algaecide

for such a short time that probably no one has yet determined with exactness the minimum dosages required to destroy the different species. Whipple's work, published fifteen years ago, gives data of this kind with respect to blue vitriol only which were the results of Moore and Kellerman's experiments a decade earlier. At Kansas City the chlorine dosage in the settling basins has been regulated with respect to its germicidal action only, but chlorine has been used for two years as an algaecide in the open storage reservoir which is a part of the City's distribution system.

A further result of prechlorination has been the elimination of Bryozoa from the filters, those strange animals so plant-like in appearance, related to the coral of the sea. These Byrozoa would formerly attain a length of several inches in the Kansas City filters, where they presented a matted appearance on the walls and a shaggy, manelike effect as they hung downward from the troughs when the filter was drained. They could be washed loose by a stream of water from a garden hose and they were periodically removed in that way. But they disappeared soon after chlorination was begun and that operation is no longer necessary.

The conditions of algae growth and control in uncovered storage reservoirs differ radically from those obtaining in settling basins. There is no continuous flow of water through the typical storage reservoir, but rather, an alternate inflow and outflow, oftentimes of such relatively small proportions as to cause an approach to a condition of stagnation. Here is such abundant opportunity for cumulative growth of plankton life that, given the extremely favorable conditions of light and temperature which are often ideally provided during the summer months, frequently the rapidity of their multiplication is best described by the word explosive. Within a day's time a relatively clear body of water may take on a very clouded appearance, due to the sudden production of countless millions of algae, usually all of one species. In the spring these will probably be diatoms, in summer, the greens, in late summer, the blue-greens, and in the fall, diatoms again, but none of these classes are strickly confined to those seasonal divisions.

Recent experiments have demonstrated the superiority of chlorine over blue vitriol for algae control in storage reservoirs, but whatever agent is used it is obvious that the method of application must be entirely different from that in settling basins. In the former it is necessary to treat the entire contents of the reservoir at one time. This may be done from a boat or, if the arrangement of the reservoir is such that the incoming water can be caused to mix thoroughly with the algae-laden contents of the reservoir, the chemical may be more conveniently applied to the influent, at a time when the direction of flow is inward, which is usually at night. As in the case of settling basins, a dosage of 1 p. p. m. has been effective in the Argentine reservoir at Kansas City, during the warm portion of the year. No treatment at all is usually necessary from October to May. In storage reservoirs the treatment is best applied intermittently, when required, and not continuously, and it is used only as often as experience with local conditions and the rate of algae growth indicate to be necessary.

The control may generally be considered as satisfactory if the number of organisms is kept down to one or two hundred per cubic centimeter. Trouble from most species may be expected if the number exceeds 1,000, and serious trouble if over 10,000. With respect to production of tastes and odors, however, quite as much depends upon the species as upon numbers, since the quality and intensity of the tastes produced varies among them, and some affect only the appearance of the water. Thirteen thousand Synedra per cubic centimeter in the Argentine reservoir in one instance elicited no complaint from consumers on account of taste.

Acknowledgment.—The foregoing is an abstract of a paper presented at the recent meeting of the Kansas Water Works Association.

Destroying Slums by Excess Condemnation.—The Regional Plan of New York and Its Environs, according to the City Record, Boston, calls attention to the fact that under the New York statutes, although not explicitly stated, excess condemnation may nevertheless be used as an indirect means of improving housing and destroying slum areas. A tract consisting of several streets and the land between them can be chosen; the land between the streets condemned; the streets closed, widened or changed in location; and the central portion of the land turned into a public park or utilized for some other public purposes. Excess land around the boundaries, not needed by the public, can be sold under proper restrictions aimed to insure an appropriate building development. By proper management, this can be done at a good profit. The public use must, however, be the primary purpose of the proceedings.

How Philadelphia Helps Relieve Traffic Congestion.—The city of Philadelphia has a plan whereby parking fields are maintained, outside the downtown districts, where motorists may park their cars for 25 cents, which also includes carfare on the Philadelphia Rapid Transit lines to and from the downtown districts. The system gives considerable relief for traffic congestion.

Street Cleaning at Toronto, Ont.

Methods and Costs of Work in 1928

THE general duties performed by the Department of Street Cleaning of Toronto, Ont., embodies the cleaning of public streets, lanes and thoroughfares, the collection and disposal of ashes and household waste material, the cleaning of catchbasins, the oiling of unimproved roadways and the removal of snow from the downtown section and main car lines. The following information relating to this street cleaning and road oiling is taken from the 1928 report of George W. Dies, Street Commissioner.

Patrol System.—The patrol system is used in the downtown business area and main business thoroughfares; that is, each patrolman has a defined area to patrol, which may be covered from one to eight times a day. According to its requirements, each patrolman is provided with a paper picking bag, push cart, broom, scraper and shovel. He covers his beat on the first round each morning with the paper bag, and removes all loose paper which may be on the boulevards, walks or roadway. He then commences his rounds, removing all street dirt which is deposited in the pushcart. As the tubs are filled, they are left at designated points, to be later picked up by a truck.

The remaining sections are under the squad system, that is, the men working in pairs, one on each side of the roadway, followed by a pick-up vehicle. This system is carried out in residential and outlying sections.

The various streets receive a cleaning once or twice weekly, according to their requirements and the funds available.

The congestion of motor traffic increases the hazard of the patrolman's work, as well as retarding the efficiency of the men. Parked motor cars and vehicles prevent the proper cleaning of the channels and the removal of litter.

The enormous amount of building which has been projected during the past year has also added its quota to the difficulties which attend this important service. These are, however, contingent perplexities which must of necessity be met by all municipal administrations and can to a great measure be coped with by adjustment of hours of work.

Each patrolman maintains on an average three miles of street, covering approximately 40,000 sq. yd., an area far too large to be properly covered by one patrolman. Street dirt should be removed as near as possible to the time of its origin, in order that vehicular traffic may not grind it into a fine dust

to be scattered by the prevailing winds to the general discomfort and annoyance of the public.

There is perhaps nothing so offensive to pedestrians than to be met by a dust-laden gust of wind. This condition is impossible to control at certain times during the fall of the year, when there are high winds and street flushing is impossible, due to the dangerous and slippery condition that would be created.

Unit Cost of Hand-broom Sweeping of Improved Roadways for 1928

Total cost (foremen, labor, cartage, supplies)	$277,866.00
Area of improved street mileage (square yards)	7,606,991
Cost of maintenance per 1,000 sq. yd. per season	$36.53
Amount of sweepings collected (cu. yd.)	105,602
Cost per cubic yard (sweeping, collecting and removing)	$2.63
Cubic yards removed per 1,000 sq. yd. per season	13.9
Number of patrolman at $28.80 per week	190
Average area maintained per patrolman (square yards)	40.037
Average number of times swept per season	90
Cost of sweeping per 1,000 sq. yd. (sweeping, collecting and removing)	$0.406

Catch Basin Cleaning.—Catch basin cleaning is carried out systematically in each Division. The general work is usually commenced immediately after the spring cleaning of the streets. During the winter season they are given such attention as may be required, in order to keep them free from ice and obstructions.

The supervision of the work is under the direction of the district foremen. In certain outlying sections, the culvert cleaning squad, which consists of two culvert men followed by a pick-up vehicle, may operate through two foremen's districts. In the downtown and business sections, the culvert man is provided with a vehicle in order that the "cleanings" may be removed immediately from the channel.

All catch-basins are thoroughly cleaned in the spring, which is usually sufficient until the fall. On main thoroughfares, subways and troublesome locations, constant attention is given throughout the season.

Many householders are of the opinion that the gutters are provided on roadways for the convenience of placing grass cuttings and lawn rakings in. This practice, in the event of heavy rain, is the most common source for blocked gratings and culverts, the material being conveyed to the gratings by the flow of water, often completely blocking the openings.

The distribution of notice cards directing householders' attention to the fact that it is a contravention of the by-law to place grass cuttings or lawn rakings loosely upon the streets, has resulted in a marked improvement in this regard. It is, however, a problem which requires the constant attention of the inspectors throughout the summer months.

Summary of Catch Basins Cleaning, 1928

Expenditure (wages, cartage and supplies)	$18,353.09
Number of cubic yards removed	12,260
Number of basins cleaned	50,621
Cost per cubic yard (cleaning and removing)	$1.49
Cost per basin per season	0.36

Flushing.—The department had in operation last season, two electric and one gasoline flusher. The electric flushers are operated under air pressure, while the gasoline flusher is operated by a centrifugal pump.

The electric flushers are confined to night flushing in the downtown section. The streets receive a flushing each alternate night. The trucks are operated together, as by this method the best results are obtained, owing to the fact that it takes a few minutes for the dirt to become saturated, so that the second flusher may readily wash it into the gutter. On this account, a light rain just before or during flushing, aids considerably in obtaining real cleanliness, and is taken advantage of by operating the flushers as single units.

The gasoline flusher was engaged upon special flushing, due to the extensive excavation work and building operations carried out during the past summer. The contractors were required to remove any material that fell from trucks when leaving the excavation or on the route to the disposal point. Owing to the extent of several of these excavations and the continuous travel of the dump trucks hauling the earth over the same route, it was necessary to keep this flusher operating on these streets.

Street Flushing, 1919-1928

Year	Street Mileage Flushed	Quantity of Area Flushed (1,000 Sq. Yd.)	Quantity of Water Used (1,000 Gal.)	Cost per Mile	Cost per 1,000 Sq. Yd.
1919	1,670	33,827	8,546	$3.44	$0.1696
1920	3,169	61,400	15,435	3.05	0.1576
1921	3,834	77,869	20,591	3.29	0.1613
1922	7,156	161,416	35,100	3.03	0.1345
1923	3,865	90,326	22,267	3.56	0.1620
1924	3,332	83,358	18,355	3.54	0.1420
1925	1,702	39,318	10,830	3.65	0.1580
1926	1,615	37,680	8,950	3.25	0.1390
1927	1,294	30,405	7,173	3.24	0.1380
1928	2,002	46,110	9,563	3.18	0.1380

Road Oiling.—During the past year 750 applications of oil were made on 304 streets and 23 lanes. Several of these received as many as six applications, while others received only one. This was due to the nature of the roadway and amount of traffic passing over it. A sandy or soft road bed will soon absorb the oil and the constant disturbance by the vehicular traffic turns up the fine dust, making several applications necessary, while on a hard surfaced or macadam roadway, one application will last several months.

The oil is applied by motor truck, which is equipped with a square steel tank with a capacity of 1,170 gal. It is applied cold by means of a 2½-in. perforated horizontal pipe, 8 in. from the ground, and at the rear of the tank. The amount of oil used is based upon the condition of the roadway, while the flow of oil is controlled by a valve, operated by a conductor on the rear platform.

The oil is purchased in tank-car loads, which have a capacity of 5,000 to 8,000 gal. These tank cars are unloaded into storage tanks by a centrifugal pump, operated by a gasoline engine, which is capable of unloading a car of oil in two hours.

There are four oil storage tanks, with a total capacity of 120,000 gal. From these tanks the motor truck is loaded by gravity, utilizing the tank nearest the district in which it is working. The first load each morning is taken from the storage tank at the Don destructor, which adjoins the garage where the truck is housed.

The necessity of an oil storage tank in north Toronto is clearly demonstrated by the fact that 70 per cent of the amount of oil used, or 183,557 gal., was applied on north Toronto streets during last season.

Four years ago, only 39 per cent of the oil purchased was applied in this district, covering 64 streets. This number has now increased to 138 streets requiring oiling. The nearest storage tank is located at the Don Destructor, which on the average necessitates a 5-mile haul. This overhaul was in a measure overcome last season by spotting tank cars of oil on the Merton Street siding, from which point the oil truck was filled by the pumping outfit. The oil truck was able to distribute a tank car of oil a day in this manner, it also eliminated a long uphill haul and covered 25 per cent more actual work. This practice was not without difficulties, and additional expense. In the event of rain, the work was discontinued, and a day or so must elapse in order that the roadway may dry out to a certain extent. This incurred demurrage charges as well as blocking the siding. There also was the expense of two men attached to the pumping outfit, while unloading the tank car. It is therefore obvious that a storage tank in this vicinity would effect a great saving, as well as increase the efficiency of the truck.

Road Oiling 1916-1928

Year	Mileage	Area Oiled (1,000 Sq. Yd.)	Gals. Used (1,000 Gal.)	Cost per Mile	Cost per 1,000 Sq. Yd.
1916	181.6	2,863	280	$125.39	$7.59
1917	180.9	2,761	244	149.28	9.78
1918	108.2	1,743	172	203.84	12.65
1919	228.	2,943	354	120.66	9.34
1920	201.6	3,353	253	232.13	19.49
1921	173.8	2,150	253	130.27	10.54
1922	244.2	3,147	361	149.28	10.11
1923	188.7	2,342	338	170.20	13.82
1924	164.	1,886	295	170.34	14.84

A Common But Fallacious Doctrine

By HALBERT P. GILLETTE

"YOU can not, in reality, prove anything by mathematics," according to Dr. Charles Lane Poor, professor of celestial mechanics at Columbia University, who has been combatting the Einstein theory of relativity for ten years. Startlingly novel as Prof. Poor's statement may sound to some people, it is quite an ancient doctrine, and none the less false because of its antiquity and the high standing of many of its proponents.

The doctrine amounts to this: Given two premises from which a logical inference is drawn, and it follows that the inference not only contains no new truth but that the drawing of the inference does not serve to establish the truth of either of the premises.

For example:

(1) All gold is malleable.
(2) This specimen is gold.
(3) Hence this specimen is malleable.

If the major and minor (2) premises are true, then the deduced conclusion (3) is necessarily true, but it is said to contain no new truth and that it does not establish the truth of either of the premises, Mill's Logic discusses this doctrine at great length, and he concludes that it is sound; but he fails to see that there is more to this matter than the mere mechanical combination of two premises to produce conclusion.

Using algebraic symbols we may write:

(1) x=a.
(2) a=b.
(3) Hence x=b.

And it is evident that the deduced equation (3) does not prove the truth of either (1) or (2), unless (and here lies the point) we put (3) to some test to determine whether it is a true equation. As a matter of fact Einstein did put his deduced equations to just such a test when he deduced the revolution of Mercury's perihelion and showed it to be in accord with actual measurements. His deduced formulas were again put to the test when he predicted the amount that a ray of light would be deflected by the sun, and the prediction was triumphantly verified.

So while it sounds quite plausible to say that you never get out of equations more than you originally put into them, it is really metaphysical sophistry; for what you truly get out of a deduced physical formula is a mathematical relation that you proceed to test by an appeal to facts. If it agrees (within the experimental or observational error) with the facts, the probability of the truth of the formula may be so great as to amount to certainty. And the greater the number of such agreements the greater the probability of the truth of the deduced formula if applied within the quantitative range that the original premises covered. Moreover, this probability increases not merely in proportion to the number of such cases, but in proportion to the product of their probability ratios. Thus if the probability of truth is 10 to 1 in a given case, and 100 to 1 in another case, and 50 to 1 in a third case, to each of which the formula is successfully applied, then the entire probability in its favor is $10\times100\times50=50{,}000$ to 1. Now it frequently happens that the probability ratios are much greater than those above given for illustration, so that practical certainty of the truth of a formula may often be attained by a single test of it, and a few such tests may raise its probability of its being true "a billion to one shot" or higher.

Among most scientists there is a curious lack of knowledge of the use of the laws of probability in testing the truth of theories. Were it otherwise, so many theories would not have remained unaccepted for decades, generations and even centuries. Couple this ignorance of the use of the laws of probabilities with a false doctrine such as Prof. Poor believes, and you begin to understand why the discoveries of so many scientists have met the same reception that Einstein's great discovery met for 15 years, and even now meets from so distinguished a person as Prof. Poor.

Lest it be supposed that the brief quotation at the head of this article does not fully represent Prof. Poor's position, the entire paragraph from which it was taken (as it appeared in the New York Herald-Tribune) will be given:

"Mathematical processes merely constitute a sort of specialized shorthand; they furnish simplified methods for carrying on elaborate and complicated arguments from assumed or stated premises. A conclusion is derived from certain definite premises, and such conclusion must inevitably involve and depend upon such premises. There is a mathematical law of conservation of knowledge, and you can never get out of any mathematical equations or formulas anything more than you put into them in the first place. You cannot, in reality, prove anything by mathematics."

I have indicated that this doctrine is false in that it fails to include what inevitably occurs in all rational research, namely, a testing of a deduced inference from an hypothesis (or premise) by an appeal to facts. And we have seen that Einstein put his theory to just such tests and that the measured results have agreed with his deduced results. All of which Prof. Poor ignores. Now let us consider a different sort of sophism in this doctrine that "you can never get out of formulas more than you put into them in the first place."

We venture to say that few students of geometry would ever embrace such a doctrine were they to follow the dictates of their own common sense. Take, for example, the deduced formula relating to the sides of a right-angled triangle, namely, that the square on the hypothenuse equals the sum of the squares on the other two sides. The deduction of this theorem might be called the greater "pons asinorum," because no geometrical ass can cross this bridge.

This theorem or formula is deduced by a line of mathematical reasoning that runs straight back to a few definitions and axioms; so apparently all that was put into the deduction was those few definitions and axioms. According to the doctrine under consideration, it was all hidden there when you read the first few and simple pages of your geometry.

If all that is in the "pons asinorum" is in those initial pages of geometry, why doesn't it disclose itself after a little inspection? Why must students struggle for weeks to get to a point where they can even understand what some Greek geometrician discovered more than 20 centuries ago?

When the average young man finds it none too easy to understand some of the pages of geometry, and still harder to remember them, to say nothing of originating such deductions himself, such a young man is not likely to swallow this doctrine without gulping rather hard.

It seems to me that the doctrine that all of geometry lies concealed in or embraced by the axioms and definitions is indefensible. The axioms lay down principles by which a thinking man may discover the properties of geometrical figures. Those properties were just as much concealed from view before the day of Euclid and his immediate predecessors in geometrical research as most of the properties of atoms and molecules were concealed from chemists before Dalton made that initial grand discovery that atoms unite in mathematical proportions as to weight.

It happens that anyone equipped with a pencil and paper, and a few drafting instruments, has at his disposal a geometrical research laboratory. True it is that few are taught to regard it as such a laboratory, and more is the pity; but by Euclid and by many another man of originality, this sort of paper and pencil laboratory was used to discover geometric properties of Nature. I say Nature, for I disagree entirely with those who think that men invented the triangle, the rectangle, the circle, the

ellipse, and all the other elementary geometrical forms. They existed in crystals, in the stems of plants and bones of animals, in the shapes of the sun and moon, in the paths of falling bodies, and in numberless other visible, natural things. But not till man began to study these natural forms did he begin to learn much about their properties. He is still learning, and perhaps never may cease learning, new geometrical properties. To say that these properties have always existed in Nature is true; but to say that they have always existed in the few simple premises (the axioms and definitions) of geometry is utterly false, if words are used to mean what common sense and custom has long prescribed that their meaning shall be.

What is true of geometry is true of all mathematics, in so far as the doctrine under discussion is concerned. Man often gets out of mathematics vastly more than he puts into his initial equations. Even where this seems not to be the case, careful analysis discloses that there has been an illusion. Take, for example, what Einstein put into his deduction that was not in any previous deduction, namely, his principle of relativity in its most general form. The rest of his premises consisted of established facts of physics and of mathematics. From these premises he deduced certain formulas. If results derived by their application to given cases agreed with the facts, such agreement indicated the probable truth of his principle of relativity; which truth, as above stated, was thus established. But this was not the sole test of its truth, for if he could deduce by aid of his principle of relativity a single formula that had been previously deduced from any established theory, then the probability of the truth of the principle of relativity became so great as to amount to practical certainty. He not only deduced one such formula, but many; the first two thus deduced being the formulas for relative length and relative time, previously deduced by Lorentz, who used established electric theories.

What Einstein put into his deductions was more than had previously existed in any similar deductions. Yet at first it seems as if he took out no more than he put in; but what he put in was a guess (even a wild guess) and what he took out was a certainty. The guess (his principle of relativity) became a certainty as a result of a mathematical deduction whose results were in accord not only with several established formulas but with two independent quantitive relations, one of which was already known but unexplained (Mercury's perihelion movement), the other of which was so novel as to be revolutionary in its significance (the gravitative bending of rays of light). If ever in all history a man took out of mathematics more than the mathematics itself contained, this is such an instance. Of course the very same sorts of amazing discoveries have been made by the aid of mathematics many times. Newton's discovery of the law of gravitation was precisely the same sort as Einstein's discovery that all energy gravitates. And in just the same way that Einstein's discovery has been belittled, so was Newton's.

Curiously enough German astronomers long argued that Newton had discovered nothing new, and that all he had found was another way of showing that Kepler's laws of orbital motion were correct. (See Herschel's Essays and Whewell's Philosophy of Discovery.) Apparently those German astronomers held very much the same doctrine as Prof. Poor holds, namely, that you can't get out of mathematics more than you put into it. But I doubt not that Prof. Poor would be among the last to agree with those German astronomers of two and a half centuries ago that Newton had discovered nothing that was not already known to Kepler; for even in the alleged cold world of science, much depends upon national and racial prejudices, to say nothing of the egotisms that make many of us loath to admit that we did not discover a thing that seems so obvious when once discovered.

The part that mathematics plays in research is that of an engine or tool, by the aid of which quantitative relations are deduced. Relations thus derived are put to the test by comparing them with facts, and if agreement is found a physical discovery is said to have been made.

The engine-like nature of mathematics is well seen in the planimeter, that truly remarkable integrating machine by means of which plotted areas may be measured. An irregular closed figure of unknown area lies before you, and a planimeter is in your hand. Does the planimeter contain that area in its mechanical head? Is the unknown area somehow concealed in this machine? The question sounds ridiculous, yet it is not a whit more so than the doctrine under consideration. Just as an unknown area does not lie concealed in a planimeter, so an unknown geometrical relation does not exist in the axioms and theorems by the aid of which that unknown relation can be discovered. Whether a formula is applied by the aid of a pencil and paper or by the aid of a machine, like the planimeter, the formula does not contain the desired answer to a question, but is merely a tool that, under certain conditions, may be used to secure the answer.

It is frequently contended that logic need not be taught as a distinct science, but that all its precepts and methods are readily acquirable during the study of other sciences. And mathematics is itself held up as an excellent illustration of a science that teaches logic. But when professed and skillful mathematicians have no better conception of its fundamental nature as a tool than to believe that the tool can contain the answer sought, and that nothing can, in reality, be proved by mathematics, it would seem needless to argue that there is crying need of the teaching of research logic as such, and not merely as an incidental part of other sciences.

John Fritz Medal Presented to Herbert Hoover

The John Fritz Gold Medal for 1929 was presented to Herbert Hoover at the Executive Mansion, Washington, Thursday, April 25, at a luncheon given by Mr. Hoover to present and past members of the Board of Awards, preceding medalists, and presidents and secretaries of the American Societies of Civil, Mining and Metallurgical, Mechanical and Electrical Engineers.

This medal is the highest honor bestowed by these four national engineering societies, having a membership of 60,000. It is awarded not oftener than annually for "notable scientific or industrial achievement, without restriction on account of nationality or sex." In accordance with custom, the award to Mr. Hoover was made tentatively and without announcement in October, 1927, and was formally confirmed and announced one year later.

At the presentation on the 25th, Dean Dexter S. Kimball, College of Engineering, Cornell University, chairman of the present Board of Award, presided and gave a brief history of the medal. He is a past-president of the American Society of Mechanical Engineers.

Dr. M. I. Pupin, a past-president of the American Institute of Electrical Engineers, and a member of the Board of Award, spoke briefly of the human elements of Mr. Hoover's lifework.

Dr. John R. Freeman, past-president of the American Society of Civil Engineers and the American Society of Mechanical Engineers, and a former member of the Board of Award, spoke of Mr. Hoover's work as an engineer.

Mr. J. V. W. Reynders, past president of the American Institute of Mining and Metallurgical Engineers, and chairman of the board which made the award to Mr. Hoover, presented the medal and quoted from the certificate which accompanied the medal the citation "To Herbert Hoover, Engineer, Scholar, Organizer of Relief to War-Stricken Peoples, Public Servant."

The ceremonies ended with a statement by Mr. Hoover.

Among the men to whom the medal has been awarded in preceding years are J. J. Carty, Elmer A. Sperry, Edward Dean Adams, John F. Stevens, Ambrose Swasey, Guglielmon Marconi (Italy), Eugene Schneider (France), Sir Robert A. Hadfield (England), Orville Wright, George W. Goethals, J. Waldo Smith, Elihu Thomson, Thomas A. Edison, Alexander Graham Bell.

The Overloading of Sanitary Sewers

Experiences in a New Jersey Town

By ALEXANDER BLAIR
Civil Engineer, Westfield, N. J.

THE cause of overloading of sewers has long been a subject of importance. In 1903 the American Society for Municipal Improvements had a discussion upon flooding, and at that time they attributed quite a large part of it to infiltration. In 1913 the American Society of Civil Engineers discussed the subject. At that time, it was shown that contributory flooding was due to infiltration. It was stated then (and Metcalf & Eddy have since confirmed the figures) that infiltration flow in sewer pipe of 30,000 gal. per mile is a maximum flow—a very heavy flow. Since that time a number of things have been tried to reduce flooding, but in order to minimize the flow the unknown sources contributing must be traced.

Leakage may be found through the walls of manholes or through the perforated slots in the tops of manholes or from pipe lines running through water courses, etc., but after finding and eliminating the sources mentioned, very heavy flooding may still be found. I have had experience with this in two towns, Summit and Westfield, N. J. In Summit about 5 years ago it was found that at certain seasons there was heavy flooding in the system. The entire sewers were gone over and every contributing cause found was remedied, but the flooding still continued.

Infiltration Not Main Cause.—At a later date in Westfield the same condition was found to exist. Only cast iron pipe with lead joints had been used for house connections since 1913, in order to reduce infiltration as well as for other reasons. Everything had been constructed absolutely tightly. All of the sewer laterals and mains since 1913 were laid with the best flexible joints known, and under rigid inspection. Strangely enough flood measurements by the writer in 1924 compared with flood flows recorded after investigation by Hazen & Whipple in Westfield in 1913 showed relatively the same high rate of flow as in 1913, the increase in normal and in flood flows being in almost exact proportion to the growth of the town. This proportion was maintained whether compared in terms of population per mile of sewer, or per house connection made, and since the construction work of the past ten years ensured tightly joined mains and connections it indicated that infiltration was not the cause of the major part of this trouble. Using the infiltration figures quoted, and they are heavy, (30,000 gal. per mile) would only account for 20 to 30 per cent of the maximum flood flows in storm periods, and the normal sewage flow would be only about 10 to 20 per cent of the maximum flood flows. Naturally, the question arose, where is the balance of 50 per cent to 70 per cent coming from?

Survey of Leader Connections.—A survey was made of leader connections, which showed that there were some old houses having leaders taking the roof drainage connected to the sewers; of course, there were a number of pipes running below the surface and in some cases it was hard to tell if those also were connected, but, assuming that they were all connected, that would only account for a very small percentage of the flow. From what source then could this excess come? It was suspected that a number of the builders were misusing the sewers as a drainage system. This was against the ordinance and I think it is so in most towns—but the builders thought that it was legitimate to make use of some existing means of drainage while constructing their houses and in many cases continued it after completion.

Misuse of Sewers by Builders.—In 1924 one violation was found in making the customary test on a sewer lateral just completed, where instead of making the usual internal hydraulic test to see what loss of water occurred when the pipe was plugged at the outlet, the inspector blocked up the outlet as usual, but left the sewer tight and dry, since there was a ground water level at that season well above the level of the sewer, by which an external test might be made. The inspector on returning was very much surprised to find the pipe filled with muddy water and traced it back to two building excavations. The matter went before the council who considered modifying the ordinance so that in future no sewer connection could be made until the building being constructed had a roof on it. A meeting was called, the builders came out in force and said they couldn't do without sewer connections when cellars were being dug as they would not have any means of draining the cellars. The council ultimately agreed that the true solution of the difficulty was the construction of storm sewers and that until they were built it would be difficult to enforce such an ordinance.

Some builders had been using patented traps, allowing a surprisingly large flow of water to pass. It was found by observation in some houses that these traps worked steadily for days after a storm. Investigation showed that after careful inspection of the house connection by the health inspector, and following his departure when the floor was ready to be concreted the builder would proceed to tap a hole in the side of the soil pipe and cover it over with stone or a piece of tin. In some cases a trap or small sump was left in the floor to which the sub drains were led and the floor then concreted concealing what had been done.

Ten Times Normal Flow.—With a population of about 12,000, the normal sewage flow was approximately 1,000,000 gal. daily. This was measured by weir at the sewage plant and verified by the water company's records of consumption. During periods of storm, after the ground had time to saturate, the flow would increase to 3,000,000 and 4,000,000 gal. daily. In extreme periods, occurring once a year, perhaps more often, when the ground water level was high and frequent and continued storms occurred, the flow has reached as high as 10,000,000 gal. per day, though this was only of brief duration. As has already been shown, the 10,000,000 gal. per day flow was difficult to account for. All manholes were inspected and found tight; and practically all had tight covers. These covers in the spring time usually had a cover of tar over them; very few of them got water in them in that way. There were no weak points in the system. It was demonstrated that the flows from brooks, water-courses, leaders, etc., could not contribute more than half a million gallons of that flow and that the houses that had roof leaders connected to the sewers would not account for any large portion of that flow.

Analyzing the Abnormal Flow.—Analyzing the flow of 10,000,000 gal. daily the respective contributions were estimated:

(1) From normal sewage flow about 1,000,000 gal.

(2) Based upon the figures of Metcalf & Eddy as stated above, about 2,000,000 gal. might be allowed for infiltration in pipes.

(3) From the roof leaders and traps in the cellars about 500,000 gal. more.

Assuming the discharge into sewer connections from cellar subdrains through patented traps and openings in house connections to be about 1,500,000 gal. more, there would still be a considerable flow left, so the cellar excava-

tions were the only reasonable remaining sources left and it was assumed that the balance of 5,000,000 gal., possibly more, must be due to this. At that time about 250 houses per year were being built and the open excavations connected with the sewer and of houses under construction would number from 75 to 100. The observed heavy flow from several cellar excavations tended to confirm these findings.

It is strongly urged that where similar conditions exist they should be followed up and it is suggested that municipal engineers and maintenance departments study their flows, tabulate them, and check up on their house construction and connections to see that there is no misuse of such connections. It is probable that this is, in many cases, the main source of heavy flows and this is urged as the strongest argument for having the engineering department or sewer maintenance force take over the work of inspection from the health authorities who are not at all familiar with these problems. It is also suggested that it would be of great value to the engineering profession as a whole in the matter of design if such studies, where made could be carefully tabulated and presented for publication later.

In good practice a maximum of 250 to 300 gal. per capita is allowed in designing most systems and any flow beyond these figures endangers treatment plants and causes the waste of large capital expenditure when additional plants and new intercepting drains and outfalls are thus necessitated.

Results of Flooding.—Flooding of sewage systems results, in the first place, in undue tension in pipe lines, the joints of which are not designed to resist such internal pressure, the weaker joints giving away, and, in some cases, sewage will flow up over the surface of the ground, out through the manholes or back into the cellars. This backing up of sewage into the cellars is a serious menace. The effect of flooding on the treatment plant is that the bacteria, most delicate organisms, which under normal flows do wonderful work in the digestion of sewage, cease to function satisfactorily, sewage is not digested, and is discharged in a raw state into the streams where it consumes the dissolved oxygen in the stream, thus kills the fish and allows mosquito breeding, as one of the preceding speakers mentioned. Attention of the speaker was drawn to this by a game warden who had stocked with fish a pond lying below a sewage outlet; sediment from sewage flowing through the treatment plant in time of flood conditions which was practically untreated, had so used up the dissolved oxygen in the pool that the fish were unable to exist, and mosquito larvae not only thrived on the sewage but no longer were eaten by the fish as is normally the case.

Acknowledgment.—The foregoing is an abstract of a paper presented at the recent convention of the New Jersey Sewage Works Association.

Action of Currents on Floating Material

In order to determine to what extent pollution of shores and beaches might have been caused by the refuse deposited at sea by New York City, the Chief Engineer of the Board of Estimate and Apportionment made an investigation during the summer of 1926 by releasing a total of 7,433 bottles with return post cards enclosed. The returns from these have been analyzed and the results submitted to the Board of Estimate and Apportionment. These bottles were released in three lots on July 1, July 7 and July 27, respectively. The first of these was placed in the water at the strength of the flood tide, the second at the strength of the ebb tide and the third at slack high water. The point of discharge in each case was about 20 miles southeast of Scotland Lightship at the dumping ground used for city garbage. Up to June 30, 1927, a total of 2,419 bottles had been recovered and were picked up at the following destinations:

Up to the latter part of August, 1928, there had been 2,444 bottles recovered, including some on the coasts of Cornwall, France and Portugal. None had been reported at points along the Atlantic Coast to the east or north of Long Island.

Destination	Number Recovered	Per Cent
Long Island	909	37.6
Lower New York Bay	55	2.3
Staten Island	1	....
New Jersey	550	22.7
Delaware	186	7.7
Maryland	97	4.0
Virginia	345	14.3
North Carolina	257	10.6
At sea	14	0.6
West coast of Ireland	5	0.2
	2,419	100.0

Mr. Arthur S. Tuttle, the Chief Engineer of the Board of Estimate and Apportionment, drew the following conclusions from this experiment:

"The results of the experiment appeared to indicate that the normal action of the currents on floating material in open water outside of New York Harbor is seaward rather than landward, and that sustained landward winds are necessary to bring about the movement of any floating material from an off-shore point 20 or more miles distant to the adjacent mainland. From the information presented , . . by the Commissioner of Street Cleaning it appeared that practically none of the garbage dumped at sea would float indefinitely, and considering the time interval required for the floating bottles to reach the mainland, that under other than exceptional conditions floating garbage, moving as a rule much more slowly, would become water-logged and sink before it could reach the shore in any appreciable quantity."

Cost of Horse Maintenance at Toronto, Ont.

The Department of Street Cleaning of Toronto, Ont., during 1928 had 383 horses in service. The care of the horses is under the direction of a veterinary surgeon, whose services are engaged on a per capita basis of $4 per horse per annum. His duties are to render the necessary veterinary services to sick horses, advise as to the proper feeding of the animals, and take the necessary sanitary precautions against disease. He also examines and certifies as to the soundness of all new purchases, and condemns animals unfit for further service.

The average life of a horse in the service of the department is 6½ years. It is therefore necessary to purchase from 50 to 60 animals each year to maintain the standard. During 1928, 50 horses were purchased at an average of $231.

A card record is maintained of each horse as to date and from whom purchased, price, color, markings, age, height and weight. The time lost by horse, due to illness or other causes, is also recorded, as well as the date of disposition, cause, and sale price.

Cost of Feeding.—The average daily rations per horse, based upon the consumption during the year, amounted to 13.2 lb. of oats, 33 lb. of hay, and 0.25 lb. of bran, while in addition 0.1 lb. of other feed was given, consisting principally of salt, vegetables, etc. Each horse was also bedded with 4.4 lb. of straw daily, while the specific rational allotment is 15 lb. of oats, and 25 lb. of hay per horse per day. This amount in many cases varied according to the temperament of the horse. On Sundays and holidays, or in the event of horses standing in the stable, only light feeding of oats is given.

The purchase of fodder supplies is an important item. Every care is exercised to ascertain that all feed is of Government standard and free from moisture, dust, or must. The importance of this cannot be too strongly stressed in order to guard against the danger of heaves, colic, distemper, and other common diseases.

The following table shows the cost per day per horse:

	Average amount per horse per day			Cost per horse per day
Oats	13.2	at $ 0.677	per bus.	$0.262
Hay	33.2	at 14.38	per ton	.237
Straw	4.4	at 10.30	per ton	.023
Bran	.24	at 35 18	per ton	.005
Salt	.04	at 22.50	per ton	.005
Daily average number horses				381.6
Total horse days				139,671
Cost per horse per day				$0.527

We are indebted to the 1928 report of George W. Dies, Street Commissioner of Toronto, Ont., for the above information.

A Proposed Traffic Plan

Method of Providing One Way Traffic for City Streets

SOME time ago Alvaro Pratt, a retired civil engineer, of Los Angeles, Calif., submitted to the Traffic Commission of Los Angeles a plan for eliminating traffic congestion on the streets of the city. A gyratory plan, similar in many respects to that proposed by Mr. Pratt, has been placed in operation in London, England, in all the chief congested areas, like Trafalgar Square, Piccadilly Circus, Hyde Park Corner and Blackfriars. In most cases the main streets were turned into "one-way" streets which called for gyration, and although it added slightly to the distance to be covered by traffic, the speeding-up is stated to have been great.

A journey along the Strand, which used to average 15 minutes during the rush hours, is now stated to be frequently done in three to four minutes. Waits of four or five minutes, which frequently occurred at Trafalgar Square or Piccadilly Circus, are now practically eliminated.

The plan as proposed for Los Angeles is described by Mr. Pratt as follows:

"Traffic congestion in Los Angeles, today, is due to the attempt of two bodies to occupy the same space at the same time. The resulting conflict and confusion cannot be remedied by literary pleas for polite road manners, wider streets, multiplication of traffic ordinances, increasing violation penalties, or doubling the traffic squad. An automatically operating, and mechanically correct plan must be provided.

"This plan should require of the auto driver a minimum of skill, experience, ability, and knowledge of the law. Such a plan will be radically different from that now in use. Some interests will be affected adversely, or will fear so, and demand 'no change.' Public officials, rusted in the old ruts, will resent new ideas. The public will require a considerable educational effort—probably a year or more.

"Absolute paralysis of traffic is only prevented, today, by the employment of alternating curents of traffic. When one goes, the other stops. Each current starts from a stand-still. The maximum effective forward motion is about 25 per cent of that of a continuous stream.

"Left hand turns around a single center button reduce this efficiency one-half, while the vehicle is turning. This reduces the effective forward motion at a one button intersection to 12 per cent of that of a continuous stream.

"Continuous stream traffic can only be secured by the elimination of the right angle crossing, and the substitution therefore of traffic stream blending in the central portion of the blocks, instead of crossing at the corners. Collisions, on one way streets, would be rare, and would consist almost entirely of real end impact. Responsibility for this should be put entirely on the car that strikes. At night there would be no adverse glare of head or spot lights—in fact the stronger the light the better for everyone on the street. Pedestrian traffic would be safer, on one way streets, as the danger would be only from one side.

"The speed of the stream between corners should be not less than eight miles per hour. No vehicle should be permitted which is incapable of being operated at that speed. Motorcycles, bicycles and horses should be prohibited. The motorcycle and bicycle, because neither their speed nor direction can be estimated by others, nor can they slow up without stopping. The use of horses on city pavements is cruelty to the animal, blockades the bulk of the other traffic, and distributes horse manure over the surface of the street.

"Fire apparatus, hospital ambulances and police vehicles might have the same rights against adverse traffic as at present. When joining with one way traffic, no tie up would be possible in front.

"Traffic stream blending between corners can only be done on one way streets.

"One way streets with continuous non-stop traffic streams, require rotary traffic within a definite district.

"Rotary traffic must proceed from right to left, as seen from the inside of the rotary district. The area of the district may be one or more blocks. The district could always handle smoothly all traffic that could be delivered by the adjacent streets.

"The plan includes the territory from Temple to Seventh and Hill to Main:

"North bound traffic—Main and Spring.

"West bound traffic—Temple, First, Second and Third.

"South bound traffic—Broadway and Hill.

"East bound traffic—Fourth, Fifth, Sixth and Seventh.

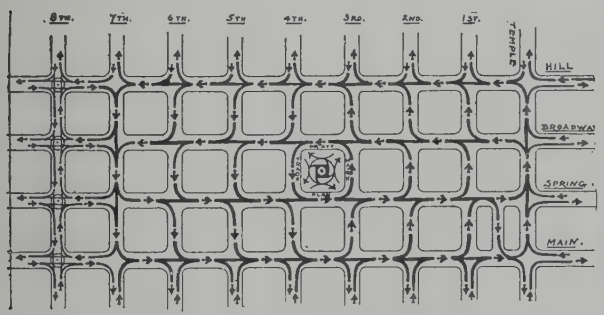

Diagram Showing How Motor Traffic Would Flow in One-Way Continuous Streams Through the Congested District of Los Angeles Under the Pratt Traffic Plan—North on Main and Spring Streets, South on Broadway and Hill, West on Temple, First, Second and Third Streets and East on Fourth, Fifth, Sixth and Seventh

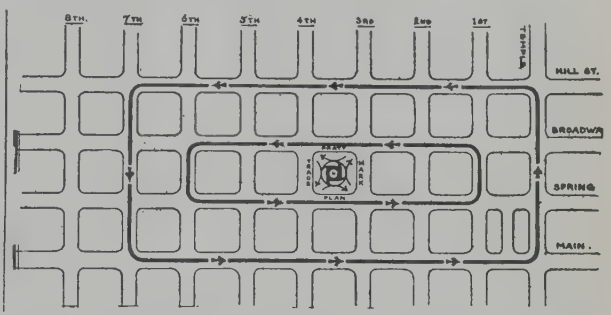

Diagram Showing Double Line Bus Routes Within Down Town Congested District of Los Angeles, as Provided in the Pratt Terminal Plan. Street Cars and Outside Motor Buses Would Stop at Terminals at the Outer Edge of the District and Their Passengers Would Be Taken Through the District as Indicated

"Tunnels and elevated ways on First from Fremont, and on Fourth from Figueroa, to Los Angeles St. will soon be necessary to carry through East and West bound motor traffic across Main, Spring, Broadway and Hill on separate grades.

"Street car traffic is possible within the rotary district, either as through service, or belt line loops. But a shuttle service from the suburb to the rotary district and return to suburb, would permit of accurate adjustment of number of cars to number of passengers; reduce by 50 per cent the "Lost Time" due to mechanical mishaps on through suburb to suburb lines, and eliminate the "Dead Time" due to traffic congestion for which congestion the street car itself is largely responsible.

"Full load terminals would reduce the car loading lost time by 90 per cent and substitute one stop for ten or more.

"Suburban traffic terminals, roofed and floored, on the edge of the "Outside Loop" would permit passengers to wait for, board or leave the street cars in comfort and safety.

"Street car and bus terminals should be located on private property fronting on the outer loop, with vehicular entrance from the next street over.

"Double belt line busses should then be provided by the street car and motor bus companies to carry their pas-

sengers without additional cost through the congested district, the busses moving with the other motor traffic around an outer loop consisting of Hill, Seventh, Main and Temple Sts., and an inner loop consisting of Broadway, Sixth, Spring and First Sts. These busses should have floor level with sidewalk, one door to enter, and one for exit, operating on the ordinary pavement with power to turn out for, or pass, each other, or other vehicles, and transfer passengers at reserved sidewalk, or street car terminal stations. No fares should be collected, cost of operation should be included in the street car fare from the suburb to the city; street car transfers being eliminated. Women, children and aged people could use the loop busses to cross intervening streets, when going in that direction. Pedestrians would presently get the rotary habit. Boarding or leaving a bus should not be more aggravating or dangerous than entering an elevator.

"The cost of construction of the plan would be probably 1 per cent, possibly 10 per cent, of the cost of either subways, or elevated railways. It would be superior to either, in the factors of flexibility of modification, cost of extension to new territory, effect on adjacent property, and stabilization of down town realty values. It would be more healthy than a subway, less offensive than an elevated, and could be abandoned at any time a superior substitute was found, with only a nominal loss of the capital invested.

"Parking: The parking or non-parking of automobiles does not effect the essentials of one-way streets, with continuous traffic stream flow. In fact, one-way traffic, of a single line, along the center of the street, would accommodate double the vehicles carried by any double line street today.

"Frontage interests will, in the final issue, determine parking, each section according to its views of its own interests—period, parallel, 90 deg., 45 deg., or none. Frontage owners today are obsessed with the idea that parking means good business, non-parking poor business, regardless of the fact that an average six-story building on a 50-ft. lot only affords parking at the curb for two cars. The shops and offices above contain from 100 to 200 clerks and professional people. Half of them have their own cars, say 100. Half of the prospective clients and customers are supposed to have cars, making a total of 200 cars to be parked. Parking capacity equals 1 per cent.

"There being, only 1 per cent enough room in the street, it is obvious the complete parking must be done on private property, if at all. Parking is mechanically feasible only on the ground floor. The shopping level might move bodily upstairs, and front on elevated or arcaded sidewalks, displacing the office tenants of the second floors, leaving the ground floor and present sidewalk areas for parking.

"Elevated side and cross walks would remove the pedestrian from the path of automobiles. The second floor would yield greater floor space, better light and be much cleaner than the present ground floor for the display of merchandise. But previous contracts, leases, and tenures, render it practically impossible for the downtown districts to avoid being abandoned by the automobile patron."

Water Supply and Sewerage in Environs of New York City

The recently issued report of the Committee on Regional Plan of New York and its environs, contains the following information on the provisions (as of Jan. 1, 1927) for water supply and sewerage in the principal communities in the environs of New York City.

Several of the communities obtain their water from two or more different sources. In New Jersey particularly there are many inter-connections between various sources of supply which have complicated the problem.

Of 330 communities in the environs which had public water supplies at the beginning of 1927, 291 were political subdivisions while the remaining 39 were nonpolitical units. There were several other small districts, mostly unincorporated, which were supplied to a certain extent by private water companies.

There were in all 150 sewage treatment plants in the environs serving the 205 communities with sewer systems. Adding the 17 plants within New York City makes a total of 167 plants in the Region, only 40 of which included some form of oxidizing treatment.

It is interesting to note the geographical distribution within the Region of the various sewerage and water supply facilities in the environs. Grouping these under the three states from parts of which the area is comprised, the following sewerage figures were obtained:

	New York	New Jersey	Connecticut
Number of communities listed	107	209	14
Those with sewer systems	60	138	7
Those with sewage treatment	39	101	6

All of the communities listed had some type of public water supply. Grouping them under a similar geographical distribution, the following figures for water supply were obtained:

	New York	New Jersey	Connecticut
Communities with municipally owned sources of water supply	47	72	8
Communities with privately owned sources of water supply	60	137	11

A summary of the sewerage and water supply figures for all of the environs is as follows:

Number of communities listed	330
Those with sewer systems	205
Those with sewage treatment	146
Those with municipally owned sources of water supply	122
Those with privately owned sources of water supply	208

Including in the water supply statistics the sources which have been developed within the limits of New York City, there was within the entire Region a total of 79 principal developed sources of surface water supplies. Of these, 45 or 57 per cent were municipally owned and 34 or 40 per cent were privately owned. There was also in the Region a total of 176 principal well stations where ground water supplies were developed. Of these, 102 or 58 per cent were in municipal ownership and 74 or 42 per cent were in private ownership.

Standing Committee Recommends Addition for Simplified Practice Recommendation on Paving Brick

Because of the increased demand for an eliminated size paving brick, the Permanent Committee for Simplified Practice Recommendation No. 1, Vitrified Paving Brick, has recommended to the industry that the wire cut lug brick (Dunn) 3x3½x8½ be reinstated as a standard type, according to the Division of Simplified Practice of the Bureau of Standards, U. S. Department of Commerce.

This size brick was eliminated from the recognized standard sizes on March 20, 1925, but the shipments for this size during the past three years has gradually increased until today it represents 14.5 per cent of the total based upon the survey of the industry in 1928. By the inclusion of the size into the simplification program, the Division of Simplified Practice stated that the degree of adherence to this recommendation is increased from 70.1 per cent to 84.6 per cent. There are now six standard, or recognized sizes of vitrified paving bricks.

In making this announcement the Division of Simplified Practice pointed out that the paving brick simplification was one of the initial projects developed by industry under the cooperation of the Department of Commerce. Much of the success attained by the program has been due to the support it has received from the Standing Committee and the National Paving Brick Manufacturers' Association.

The Division of Simplified Practice is the only organization engaged in waste elimination, through simplification and standardization, that subjects the effected programs to stipulated review, in order that they may be revised or modified in order to keep them abreast of current developments in the industry.

The Cause of the Severe Winter Weather of 1928-29

Eleven years ago there occurred an exceedingly severe winter. History has just repeated itself, but doubtless some of the "frankly skeptical" astronomers will remain "frankly," although perhaps not so loudly, skeptical about the influence of sunspots on weather. It is no easy matter to change a scientist's mind once it has been well coagulated by a false doctrine.

There is a great sunspot cycle that reaches its maximum in number of spots about every 11.2 years, and it has been doing this with remarkable regularity ever since astronomers began counting sunspots about three centuries ago. On several occasions since those counts began (9 to be exact) the sunspot maximum did not occur within 18 months of the time that the so-called 11-year maximum was due. But on the remaining 20 times out of the total of 29 (counting from 1615 to 1928) the 11-year spot maximum came very nearly on time.

In the October, 1928, issue of "Municipal News and Water Works," an article gave the results of a long research by the editor as to the cause and periodicities of sunspots. In that article many sunspot cycles were listed, and each of the 8 planets was credited with a cycle; the date of the last maximum and the exact length of each cycle was given, so that anyone could check the results on a chart of the sunspot curve. A table was printed showing the dates of each of the 28 sunspot maxima from 1615 to 1917, and the dates of maximum sunspot influence assigned by the editor to Jupiter, Uranus and Neptune. It was shown that Jupiter, the largest of 8 planets, is responsible for the spot cycle of 11.21 years; when Jupiter's north magnetic pole points most nearly toward the sun, then Jupiter creates the most spots. Each of the other planets produces its maximum effect in a similar way; and because the magnetic poles of their upper magnetic fields are all revolving westward about their axes of rotation, the sunspot cycles that they cause are invariably shorter than their periods of orbital revolution. It was shown that 3 different times when a great sunspot maximum did not occur on or near a date assigned to Jupiter, it did occur on or near a date assigned either to Uranus or Neptune, those two planets evidently having more powerful electromagnetic effects upon the sun because their axes point much more directly toward the sun.

Since the next peak effect of Uranus is not due till 1951, and that of Neptune not till 1998, it was shown that Jupiter's 1928 sunspot peak would not be interfered with by either of those planets, and that the Jupiter peak would occur about Nov. 1, 1928.

Sunspots having anti-clockwise rotation are the main causes of our cyclonic storms. Nearly all storms are cyclonic, and in their whirling nature they are closely kin to the sunspots by which they are caused. Sunspots are known to be electromagnets (due unquestionably to the free electrons in the whirls), and the editor has reasoned, both by analogy and deductively, that our cyclones are electromagnets, electrically generated, electrically whirled and electrically propelled. He has been able to explain cyclonic phenomena far better by this theory than it has been previously explained by a combination of theories in which convection currents and centrifugal force are supposed to play the star roles.

Storm tracks (i. e., the paths of the centers of cyclonic storms) are often parabolic. This discovery was based on the electromagetic-whirl theory, and is explainable by no other theory. In fact it was not perceived by meteorologists because their theories did not guide them to look for it.

Storm tracks shift to higher latitudes during sunspot peaks, and thus produce weather anomolies. It is such anomolies that have puzzled many astronomers and have led some of them to express skepticism about the influence of sunspots on weather. One very cocksure astronomer has wittily said that predicting weather by the aid of sunspots is like trying to forecast which way an elephant will walk by studying the migrations of a tick on the elephant's ear. It may be replied that predicting weather far ahead without the aid of sunspots is as futile as to try to calculate planetary interactions unguided by a knowledge of gravitation.

The statistical literature showing quantitative relationships between sunspots and weather is already prodigious. Its very bulk apparently deters most astronomers from even glancing through it. The seeming inconsistencies and anomolies with which this literature abounds are even more forbidding. But in every other case where quantitative relationships have been discovered, diligent study has led to an untangling of the maze and a disclosure of the underlying simplicity of the phenomena.

The Tensile Strength of Water

When capillary attraction was first discovered it was thought that the answer had been found to the question, Why does sap rise? But capillarity was soon found to be inadequate. Later came the discovery of osmotic pressure, and again it seemed that the answer had been secured. Physicists have finally concluded that no forces known to act upon sap can account for a rise of more than about 150 ft., yet it rises more than double that height in the tallest trees.

Prof. H. H. Dixon, of the University of Dublin, has recently proved that water in capillary tubes has a tensile strength of several hundred pounds to the

square inch. Since this would suffice to lift a capillary column of water to the tip of the tallest tree, he has inferred that evaporation of the water in the leaves furnishes the lifting force. He becomes rather vague in trying to show how evaporating molecules exert a pull on the surface of water that they are leaving.

When a liquid evaporates it expands into gas, and gas would presumably exert a back pressure on the surface of the liquid, instead of a pull upon that surface.

The thought has occurred to us that when water in a capillary tube acquires tensile strength, it may be because some of its electrons are rotating in planes perpendicular to the axis of the tube. Each electron rotating in this manner would constitute an electric current, and since parallel electric currents attract one another, tensile strength would be produced in the column of water. The water column would resemble a magnet, and in fact would be a fluid magnet.

Such a magnet might then be forced up by the magnetic field of the earth, just as air in cyclonic air-whirls seems to be forced upward. And thus a more complete explanation of the phenomenon of the ascent of sap would be had.

Although there may seem to be no way in which the hydraulic engineer can utilize such a principle, let us not be too skeptical of our inability to apply it. It is evident that ways can be devised for releasing more electrons in water. Ultraviolet light, for example, effects release of electrons, and we are convinced that magnetic fields effect release of electrons. Picture, then, a pipe of small diameter into which highly electrified water is introduced at the base under the influence of a magnetic field that gives rotation to the electrons about the axis of the pipe. It is probable that the magnetic field of the earth would lift the water to a considerable height, and thus furnish the lifting energy free of charge.

What plants have learned to do on a small scale, engineers should be able to do on a large scale. The first step, however, consists in securing a full understanding of the reason why sap rises to the top of giant sequoias.

Hats Off to the Jack-Of-All Trades

Upon a time not so long ago, to be dubbed a jack-of-all-trades was to be labeled a worthless fellow. Perhaps the day is not far distant when that term will be regarded as one expressive of the highest approval. Ability to shift quickly from one occupation to another characterizes so many American workers as to have attracted the attention of some foreign visitors, but we do not recall reading that any of them saw in that versatility one of the main reasons for the economic progress that they envy.

Recently an English periodical published an account of the woeful experience of a shipyard worker who has been out of a job for several years, living on a small dole. The most instructive part of the tale was unintentionally written between the printed lines; for, although never explicitly stated, it was tacitly assumed throughout that the misery of this man would not end until ship construction again reached a degree of prosperity sufficient to give him back his lost job. While there are still some American workers who would thus wait years for their lost jobs to return, their number is relatively few, and steadily decreasing. A shipworker today, a farmer tomorrow, a truck driver the next day, and any old job thereafter, may not seem like good training for the man aiming at high wages, but none the less it has resulted in the highest average wages in the world.

Of course the prime reason for American high wages is great productivity per worker, and this is first of all due to science and invention; but neither science nor invention can operate effectively in the service of man unless there is freedom to apply the discoveries that they yield. In countries where workers regard themselves as irrevocably tied to their particular trades, it is not surprising to find it very difficult to introduce labor-saving devices. When a man feels that if he loses his job as a riveter in a shipyard and no other sort of job can be had, that man is sure to oppose any device that will enable men to drive more rivets; and if riveting were to be replaced by welding, well—! Great Britain is full of just that sort of men, with just that sort of attitude toward their jobs. The world war served to strengthen that attitude, and the dole was a political device that made the typical British worker more determined than ever to cling to the old tradition. No jack-of-all trades, he.

So long as most products were handmade, and required a deal of skill in their production, a shifting from one sort of trade to another was almost prohibitive. With the advent of machines in which the skill of the worker had been superseded by the "skill" of the mechanism, there suddenly came a change, or at least it would have come suddenly had not habits been of a stuff that changes slowly. The built-in-skill of the machine meant more freedom for the worker, freedom from years of apprenticeship at beggarly wages, and what is much more important, freedom to shift from one machine-tending job to another almost over night. This last-named freedom explains, in large measure, the absence of strong opposition to labor-saving devices in America.

British investigators come, and see, but do not comprehend. They go back with talk about "mass production," "high wages as a cause of great demand," and the like, but they fail to see that freedom is the one great factor that British industry lacks. There must first come a different outlook upon the job, the outlook begotten of knowledge that machinery can be used to free men from the tyranny of industrial caste, and there must come faith in a future where such freedom exists. This outlook and this faith are not to be created by any fiat, nor even by the most logical arguments. Outlook and faith are unfortunately matters of slow development; but the development can undoubtedly be hastened by judicious oft-repeated presentation of facts. America furnishes the facts without limit, but apparently they need to be interpreted to other nations; for even the men who come looking for them, leave without recognizing the most important fact of all, namely, industrial freedom.

H. P. Gillette

New Books

"Economics of Highway Bridge Types" by C. B. McCullough, Bridge Engineer, Oregon State Highway Commission; Member American Society of Civil Engineers; Member Oregon Bar; Special Lecturer in Structural Engineering, Oregon State College. First edition, 246 pages, 5¾ in. by 8½ in., hard cover, cloth binding; Gillette Publishing Co., Technical Publishers, 221 E. 20th St., Chicago, Ill., publishers. Price $5.00 net.

You have often heard the expression, "He could not see the forest because of the trees." The function of this book is to place the reader on a hill or in an airplane, as it were, to survey the forest. In other words, McCullough analyses the crossing problem from the broad viewpoint of selecting an economic type of bridge from amongst the many types that may be constructed.

This text has been compiled with a view to its utility not only to the practicing highway engineer, county engineer, city and consulting engineer, but to the undergraduate student in highway and civil engineering as well.

A prominent feature is the fact that the discussion has been prepared for the highway engineer in general rather than the highway bridge engineer.

The many cost and quantity curves and data sheets have been made sufficiently general in application to cover average practice and govern estimates of cost of structures designed according to general practice. The tables and curves should prove of great benefit to the engineer in the field engaged in highway location or relocation, to highway maintenance engineering organizations and to field parties, divisional organizations, municipal and county engineers and others engaged in the construction, location or design of highway bridges.

To the student in engineering this work should serve a two-fold purpose. First, as an outline of bridge economics and type selection in general it serves to direct his attention to a most important phase of bridge engineering and one to which scant time is given in most engineering curricula. Second, the many cost tables, curves and illustrations, covering in fact practically all of the commonly employed types in highway bridge construction, will serve to give him a rather thorough and comprehensive survey of the ordinary construction types, these affording him an opportunity to develop the necessary and much to be desired general perspective of the subject before taking up the complicated minutia of design and design methods.

"Prometheus, U. S. A." by Ernest Greenwood, author of Alladin, U. S. A., etc. First edition, 213 pages, 5½ in. by 8⅛ in., hard cover, cloth binding, illustrated, Harper & Bros., New York City, publishers. Price $2.50.

Beginning with the tales of fire as they are chronicled in myths, legends and the history of its uses down through the ages, Mr. Greenwood considers at some length the modern methods of uses of fuels and their relative merits in industry and home. He has collected a large amount of material on oil, gas and electric light and power and has been able to sketch the picture of the distribution of these agencies for their multitudes of present-day employments. "Automatic heat," he summarizes, "is the latest achievement of man in employing fire for his comfort and for industrial purposes."

Wood is referred to as the first fuel and one of the bulwarks on which this country was built. Facts are given on the supply of wood now available and what is being done to assure a continuing supply for future generations, pointing out that wood is no longer to be considered as a major fuel.

In summarizing the part that coal has played in the history of fuels, the author says,

". . . to coal goes the credit for building the very foundations of American industry and it will be a long, long time before it is entirely replaced by oil, water power or some synthetic fuel of the future.

"Without coal, our transportation system, the greatest in the world, would still be in its early stages of development. Coal was an important necessity in the smelting of iron so necessary for the rails and the equipment of our railroads. Coal was the only kind of fuel that was available in the early days; how far would our railroads have travelled if they had had to depend on wood? Coal was an absolute necessity to run the industries which eventually produced the machinery from which our water-power generating plants are built."

Following this, the gas industry is discussed, Mr. Greenwood citing instances of its early discovery and the difficulties that attended its commercial introduction in the last century in England and America. He includes a considerable amount of statistical information about the industry as it exists in this country today, pointing out that, as is the case with the light and power companies, gas companies necessarily are monopolies in the communities they serve. Other sections of this discussion deal with who owns the gas companies; coal as direct fuel and as raw material for making gas; coke and other by-products.

About automatic heat, as it is supplied by the modern oil burner or the modern gas heater, he says; in part: "There are many things of social significance which are accomplished by automatic heat aside from pushing into the background another piece of the ugly machinery of life. The growing desire for apartment house life is due, to a considerable extent, to the dread of the furnace in the basement. No one who has ever tried it will deny that the private house provides a far more satisfactory home life, particularly when there are children, than the apartment, which at best always has something of the atmosphere of a hotel and which almost always lacks the comfort of spaciousness to be found in even the most humble of dwellings."

"Prometheus" is easy to read. And it is a welcome addition to the library of popular books dealing with Industrial America.

"The Arithmetic of Sewage Treatment Works," by Karl Imhoff, Chief Engineer, Ruhoverband, Essen, Germany; Member American Society of Civil Engineers; translated from German by G. M. Fair, Asst. Prof. of Sanitary Engineering, Harvard University, Cambridge, Mass. 99 pages, 4½ in. by 7 in., flexible binding. John Wiley & Sons, New York City, publishers. Price, $2.00.

This little book is intended to assemble in small space the methods of computation commonly employed by sanitary engineers in the design of sewage treatment works. Statements of methods have been made brief. Exact mathematical calculations do not lead very far in the design of sewage treatment plants because the methods are based on practical experience.

"Financing of State Highways," compiled by Julia E. Johnson. First edition, 209 pages, 5 in. by 7½ in., cloth bound in hard cover. The H. W. Wilson Co., New York City, publishers. Price. 90c.

This book is based primarily upon the issue of bonds for highway purposes. It includes discussion of the sources of taxation to be drawn upon for financing and such practice, principles and breadth of discussion as abstracts permit. It is compiled from abstracts as shown in the bibliography and arranged for debating purposes.

"Building Estimators' Data Book," by Chas. F. Dingman, Architectural Engineer. First edition, 159 pages, 4 in. by 6½ in., flexible binding. McGraw-Hill Book Co., New York City, publishers. Price, $2.50.

This little volume is an addition to Mr. Dingman's other works and contains all of the estimating data that appeared in the other book, as well as more new and original material. The data is condensed and tabulated for ready reference, using the unit system of estimating.

A list of standard symbols for wiring plans is included.

"Masonry Dams," by William P. Creager, C. E., Member American Society of Civil Engineers. Second edition, 294 pages, 6 in. by 9 in., cloth bound, hard cover. John Wiley & Sons, New York City, publishers. Price $4.00.

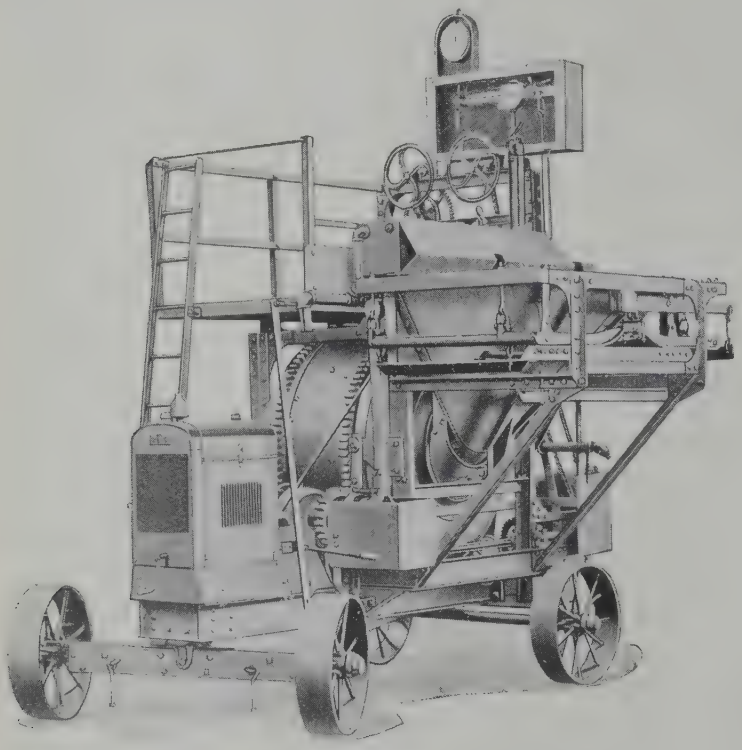
This is a review of the text of the first edition with obsolete matter removed, new material on newer developments included.

The book includes diagrams for quantities in solid gravity dams, backwater computations, fuller description of outlet control and flood gates and new chapters on arch dams and flood flows. Like sewage treatment engineering, this branch of civil engineering is based largely on practical experience and data learned from failures. The theory on which the design of masonry dams is based, the author acknowledges, is not exact, and, moreover, has not been verified by satisfactory experiments.

A New Mixer Attachment Weighs Water and Aggregate

A new mixer attachment called the Weigh Mix was recently developed by the Koehring Company of Milwaukee, Wis., manufacturers of pavers, mixers, power shovels and cranes.

This machine was brought out in response to a desire by contractors for a portable concrete manufacturing plant that could be charged with available equipment and which would be capable of accurate proportioning of materials by weight.



Weigh Mix Attachment for Standard Koehring Mixers

The Koehring Weigh Mix satisfies these requirements and fulfills the needs of the building contractor. It consists of a standard Koehring mixer, equipped with a weighing batch hopper and water tank mounted on an auxiliary frame carrying pipe lever scales.

All operations are controlled from the operating platform by one man. Materials are weighed into one hopper, thereby allowing for the use of as many aggregates as may be desired; gravel is normally weighed in first, followed by cement and sand; the water is weighed on the same beam and is carried in an open tank.

When the batch hopper door opens to allow for the charging of the mixer, the batchmeter is actuated and the hopper shaking device, operated by a cam on the main driving shaft, is started. The batch hopper discharges quickly, cleaning perfectly so that the scale will return to balance.

By mounting the weighing batch hopper on the mixer, head room is reduced as compared to the use of independent weighing or measuring devices. This allows a compact arrangement of controls for one-man operation. Due to the shape and position of the hopper, bulk cement and any number of differently graded aggregates can be weighed without additional equipment.

The batch hopper does not come in contact with the weighing mechanism while being shaken and therefore the accuracy of the weighing mechanism is not affected. The scale beam is boxed so that it can be taken off the plant for transportation, thereby insuring against damage.

The Koehring Weigh Mix is practical in design and is successful in operation. Although new, it has already attracted favorable attention from engineers and contractors who have been in touch with its operation.

Upon request the Koehring Company or any of its sales offices will send a special circular describing the Weigh Mix.

Cast Iron Pipe 18 Ft. Long Now Manufactured

Eighteen foot lengths of deLavaud centrifugal cast iron pipe in all diameters 4 in. to 12 in. inclusive has just been announced by the U. S. Cast Iron Pipe & Foundry Co.

A battery of casting machines for the production of deLavaud pipe in 18-ft. lengths is now in operation at Birmingham, Ala. and the product will be found to measure up in every respect to the high standards established by deLavaud centrifugal pipe in 12-ft. lengths.

The advantages of 18-ft. pipe can be readily visualized when it is considered that as compared with 12-ft. lengths of pipe there is a reduction of 33⅓ per cent in the quantity of jointing materials required, in the labor of making the joints themselves and digging the bell holes. In the construction of plain end pipe lines for gas the use of 18-ft. lengths reduces the cost of couplings, or special connecting pieces, 33⅓ per cent and correspondingly reduces the labor involved in the installation of such couplings or special connecting pieces. Another feature is that with the longer lengths that are fewer number of joints which reduce the number of possible points of leakage in the finished line.

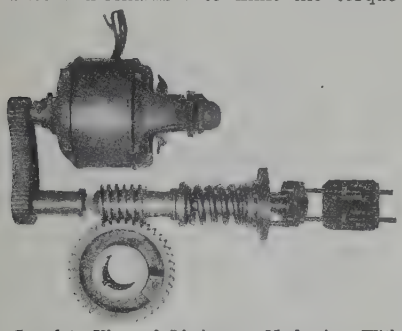
The equipment for handling the 18-ft. lengths of deLavaud centrifugal pipe need be no different from that used in handling 12-ft. lengths of cast iron pipe. For example, the standard weight of an 18-ft. length of 8-in. Class 150 deLavaud pipe, used for 150 pounds maximum working pressure, is 629 pounds. Compare this to the standard weight of a 12-ft. length of 8-in. Class C, sand cast pipe used for 130 pounds maximum working pressure which is 625 pounds; in other words, while the 18-ft. deLavaud pipe is 6 ft. longer than the 12-ft. Class C sand cast pipe, it allows an additional working pressure of 20 pounds and weighs only 4 pounds more.

On account of the decreased weight per foot, as compared with the same diameters of sand cast pipe, the same number of men can be used to install 18-ft. lengths of deLavaud centrifugal pipe as are used for the installation of 12-ft. lengths of sand cast pipe.

Loading Car with 18-Ft. Cast Iron Pipe

Limitorque Improved

The Limitorque Corporation, New York City, have developed a mechanism for operating valves, doors, etc. It is a reversible motor driven reduction gear valve controller with a mechanical switch mechanism to limit the torque



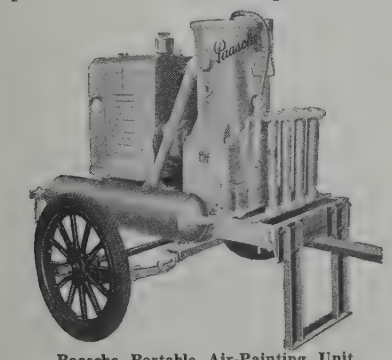
Complete View of Limitorque Mechanism With Case Removed

and travel of a slow speed shaft in both directions. Power may be electricity or compressed air, remotely controlled.

It operates through one pair of heavy grease lubricated worm gears, in an oil tight casing. The manufacturer states that Limitorque has a torque switch that stops the valve gate only when it is properly seated, regardless of travel. The valve gate may be closed to any desired degree of tightness. All seating and unseating strains are absorbed by a heavy compression spring. A positive unseating blow is administered at slow speed directly to the valve stem nut.

Air-Painting Trailer Unit Announced

The Paasche Airbrush Co., Chicago, Ill., announce the production of a new Paasche air-painting unit, a two-wheel trailer—new in design—that goes anywhere. It is equipped with a 64-ft. patented water and oil operator that



Paasche Portable Air-Painting Unit

removes water, oil, dirt and moisture from the airline, thus assisting in producing a better finish.

Paasche air-painting units, the manufactures claim, are the only portable units equipped with these patented water and oil separators.

New Pump Operated by Outboard Motor

A new type drainage pump, which is powered with a Johnson outboard motor and which is unique in that it is self-priming and will shut itself off when the water being pumped is stopped or gone, is now being manufactured by the Johnson Motor Company, Waukegan, Ill.

This pump consists of a long pump shaft with a light twin-cylinder outboard motor mounted on the top. This motor powers the impeller which is located at the bottom of the shaft. As the pump shaft sinks to the bottom of the water and the impeller is always submerged no air can be sucked while there is still water to be pumped. Thus delays in priming are eliminated. In addition starting difficulties are also eliminated as the water begins to flow immediately after the motor is started.

The automatic shut-off prevents the pump from burning out on the job. A

Johnson Portable Pump

workman can start it and can go away and forget it, for an ingenious safety device short circuits the magneto of the motor when water is not passing through the pump.

Some types of work to which this outfit is adopted includes pumping water from excavations, concrete forms, manholes and barges. It is also found highly useful in dredging work of all kinds.

It will pump 195 gal. of water per minute and 1,000 gal. for the approximate cost of one cent, according to the manufacturer. It can do in five minutes what would require an hour and a half for one man with a hand-operated pump and will do with a half gallon of gasoline what another unit may do on a quarter ton of coal, it is claimed. The outfit weighs 85 lb. and can be carried by a man.

Further information about this new pump may be secured from J. H. Sheldon, Johnson Motor Co., Waukegan, Ill.

A New Sewer Pipe Joint Material

The Standard Oil Company of Indiana announces an asphaltic product for making leak-proof sewer pipe joints. The product is known as No. 1 Korite (Brand 6775). No. 1 Korite is said to make a permanent, tight joint, and to prevent the leakage, infiltration and choking of pipes by roots. It is quickly prepared for use, and easily applied by an intelligent laborer.

It has been used on sewer pipe installations in various localities. Tests conducted by the engineers of the Clay Products Associations have proved that the No. 1 Korite is a satisfactory material for making a permanent, leak-proof joint.

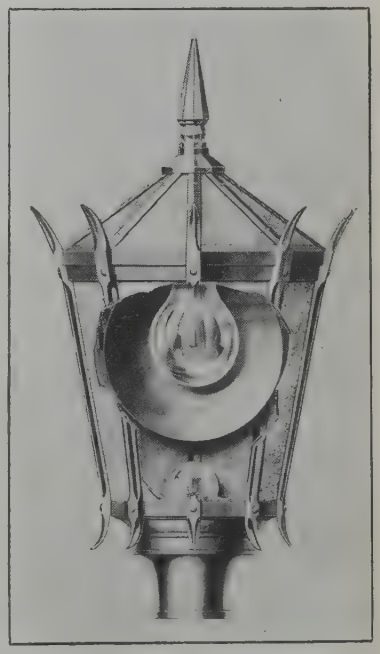
Copies of the No. 1 Korite folder, describing this product may be had by writing to C. C. Lakin, Manager of the Asphalt Department, Standard Oil Company (Indiana), 910 South Michigan Avenue, Chicago, Illinois.

Ornamental Floodlights

The King Luminaire Company, 37 West Jackson Boulevard, Chicago, have added ornamental floodlights to their wide range of ornamental industrial lighting equipment.

King Luminaire floodlights are unique in that the floodlight reflector and lamp are enclosed in a King Luminaire ornamental lantern, eliminating the unsightly reflectors that have been used in the past, thus serving the dual purpose of a floodlighting lantern, plus the ordinary illuminating functions.

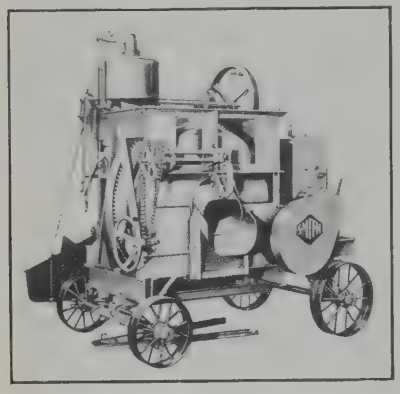
King Luminaire floodlights may be had in a wide range of designs and sizes to meet the most exacting needs and tastes. Industrials interested in illuminating and beautifying buildings and grounds can secure literature by writing Mr. O. M. King, President, King Luminaire Company, 37 West Jackson Boulevard, Chicago.



King Luminaire Floodlight

A New Half-Yard Mixer by Smith

The T. L. Smith Company, independent division of the National Equipment Corporation, and mixer builders for the past 30 years, are now



Newly Designed Smith 14-S Non-Tilting Mixer

introducing a new 14-S non-tilting mixer said to be unusually simple in construction and fast in operation.

The drum is of typical Smith design, bigger in diameter and narrow, with 10 deeper full-width discharge buckets and bigger drum openings than former models. It is claimed that these drum improvements permit the use of a wider-throated skip and wider discharge chute, time saving features that assure quicker loading and faster discharge. Complete front end operation is provided, with both charge and discharge sides of the mixer visible. The drum rollers are equipped with oversize Timken bearings in dust tight housings.

Other features include: pressed steel drum heads, short swinging discharge spout and auxiliary stationary spout, band friction hoist clutch and brake, low hot-riveted frame, forged steel rear axle brackets, and wheels that turn under the frame for easy handling. Optional equipment includes a newly designed batch hopper with large swinging gate.

Arco Metal Pipe Enters Water Works Field

Arco metal pipe is a threaded joint corrosive—resisting high quality cast pipe made of alloy iron. It can be cut and threaded at any point within its own length with all standard tools which are used on wrought steel or iron pipe and does not have to be reamed after cutting.

The following statements are made by the manufacturer, the American Radiator Company, New York City:

1. It is true to dimensions, smooth outside and inside.
2. It is free from casting stains
3. It is uniform in wall thickness.
4. All standard floor tables for extra strong wrought steel and iron pipe can be used to figure the capacity of Arco metal pipe.
5. It is resistant to both corrosion and erosion and will not scale inside.

Arco metal pipe is made from a special analysis ni-chrome alloy iron and cast by a process which gives the resultant greater ductility and tensile strength, and also, due to the close grain structure, greater corrosion and erosion resisting qualities than ordinary gray cast iron.

Arco metal nipples and fittings are made for use with the pipe. The pipe is made in sizes from 1½ in. to 6 in. inclusive.

Dietz Announces Roadside Torches

To satisfy a certain amount of demand for roadside torches, which are legal in some states for highway construction work, the R. E. Dietz Company has recently introduced two models. No. 96 is a spherical torch having a weighted bottom which causes it to return to position if tipped or

New Dietz Roadside Torch—No. 96

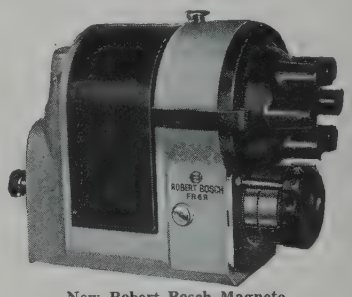
knocked over, while No. 80 is a semi-special torch with a broad, stable, unweighted base and curving sides that operates as a fend against injury. These torches burn either kerosene, light fuel oil or crude distillate. Each is provided with a cast steel burner, heavy carrying loop and an automatic lock that prevents the wick from slipping. They are packaged three in a carton and distributed through the jobbing trade exclusively.

For further information write the R. E. Dietz Co. of New York.

Robert Bosch Announces a New Super-Energy Magneto

A new magneto for 6-cylinder engines has recently been announced by the Robert Bosch Magneto Company, Inc. This instrument, known as type FR6, is designed especially for use on truck, bus, marine, stationary and similar engines where large cylinder capacity or high compression make a powerful magneto desirable. The general appearance of the type FR6 magneto closely resembles that of the Robert Bosch FU type. The chief apparent difference,—besides its slightly larger size,—is the distributor plate which has the high tension outlets at the front instead of at the top. Generous margins of safety are provided to take care of the high voltages developed. The collector ring and certain other electrical parts have been increased in size.

The type FR6 magneto generates an



New Robert Bosch Magneto

igniting spark at 30 crankshaft r.p.m. This insures an effective starting spark even at the slowest hand crank speeds. It is recommended for engines operating normally up to 3,000 r.p.m., which covers practically the whole range of commercial engines.

This magneto has all the features characteristic of Robert Bosch Super-Energy magnetos, which have proved highly successful under all sorts of operating conditions. These features include permanently lubricated ball bearings, gap type distributor, dust proof and water proof construction and one piece aluminum alloy frame.

Sidewalk Snowplow Announced

La Plant-Choate Manufacturing Co., Cedar Rapids, Iowa, has just built a side walk snowplow for crawler tractors. It is the answer to the side walk clearing problem in the snow belt where horses are too slow. Write the factory for a catalog or call on some dealer for information.

Sidewalk Snow Plow by La Plant-Choate

Municipal News and Water Works

Vol. LXXVI JUNE, 1929 No. 6

The 1929 Convention of American Water Works Association

49th Annual Meeting Meets June 24-28 at Toronto, Ont.

THE 49th annual convention of the American Water Works Association, which is to be held June 24-28 inclusive at Toronto, Ont., will be one of the most important meetings ever held by this association. Action will be taken at the convention on the adoption of a new constitution for the association.

Royal York Hotel, Where 49th Annual Convention of American Water Works Association Will Be Held

The New Constitution. — The new constitution, the result of a year's deliberation by a committee appointed at the 1928 convention. Its main feature is the formation of a board of directors, which will have full control of all activities of the association. The board will appoint all committees and provide for the general administration of the affairs and property of the association.

The board of directors will consist of the president of the association, the treasurer of the association, the latest living past president of the association, the chairman of the committee on water works practice, the chairman of the publication committee, one director elected by the members of the Water Works Manufacturers Association, and one director elected by each section of the association. This later representation means that every part of the territory covered by the association will have its representative and will have a part in formulating and executing the policies of the association.

The board of directors will meet each year at the annual convention and it is also proposed to have a meeting in January of each year at which all the directors will be present. In order to give continuity to the board membership the term of the directors representing the sections will be so arranged that approximately one-third of them will retire each year.

The new constitution also provides for an executive committee consisting of the president and four directors, which will direct the administrative work of the association and carry out the policies of the board between meetings of the latter. This committee will be chosen by the board at its meeting at the annual convention.

Provision also is made in the new constitution for additional conventions or regional meetings, but such meetings are only to be held as found advisable. In general, they would be held when and as desired by the sections in any portion of the territory covered by the association.

The Convention.—The headquarters of the convention will be at the new Royal York Hotel, which was officially opened on June 11. The entertainment which will be given at this convention includes a reception and dance the opening night, theatre and card parties, bus rides, tea at the Yacht Club and a shopping tour for the ladies; smoker for the men and a dinner dance for everyone on Thursday evening.

The delegates will be given an opportunity of inspecting the water works system of the city of Toronto and trips to the different stations and filter plant will be arranged upon registration.

Exhibits.—Nearly 100 manufacturers of water works supplies will show their products in the large hall on the convention floor of the Royal York Hotel, and already this large room, 62 ft. by 164 ft., is unable to accommodate everyone who desires to be represented at this meeting.

The following is a list of the exhibitors who have been assigned space.

The program of the 49th annual convention follows:

MONDAY, JUNE 24, 1929

Forenoon

8:00 Registration.

9:00 Committee on Water Works Practice.

Malcolm Pirnie, Chairman. Hazen, Everett & Pirnie, Consulting Engineers, 25 W. 43rd St., New York, N. Y.

11:00 Executive Committee.

Afternoon Sessions

Plant Management and Operation Division and Superintendents' Round Table Discussion.

H. F. Huy, Chairman, General Manager, Western New York Water Company, 11 Niagara St., Buffalo, N. Y.

2:00 Ball Room.

The following members will lead the discussions:

J. W. Ackerman, Watertown, N. Y.
W. W. Brush, New York, N. Y.
C. K. Calvert, Indianapolis, Ind.
W. S. Cramer, Lexington, Ky.
F. C. Dugan, Louisville, Ky.
J. E. Gibson, Charleston, S. C.
D. E. Kepner, Denver, Colo.
M'Kean Maffitt, Wilmington, N. C.
W. S. Patton, Ashland, Ky.
A. U. Sanderson, Toronto, Ont., Can.
J. F. Skinner, Rochester, N. Y.
L. A. Smith, Madison, Wis.

2:00 West Hall.

Committee No. 1—Standard Methods of Water Analysis.

J. J. Hinman, Jr., Chairman, Associate Professor of Sanitation, University of Iowa, Iowa City, Ia. Everybody welcome.

Evening

9:00 Informal Reception and Dance. Concert Hall.

Address of Welcome—Mayor Samuel McBride of Toronto.

TUESDAY, JUNE 25, 1929

Forenoon Sessions

9:00 Ball Room.

Opening of Convention.

William W. Brush, President.

Announcement of Officers and Trustees elected for the year 1929-30.

Reports of Secretary, Treasurer and Executive Committee.

Action on Budget.

Report of Committee on Water Works Practice.

New Business.

Conference of Committee No. 19, Boiler Feed Water Studies.

Sheppard T. Powell, Chairman, Chemical Engineer, 213 St. Paul Pl., Baltimore, Md.

9:00 West Hall.

Recent Developments in Boiler Operation and Their Influence on Feedwater Treatment.

Sheppard T. Powell, Chemical Engineer, 213 St. Paul Pl., Baltimore, Md.

Deaeration of Boiler Feedwater.

J. R. McDermet, Research Engineer, Elliott Company, Jeannette, Pa.

The Dissociation of Water in Steel Tubes at High Temperatures and Pressures.

Illustrated by Lantern Slides.

C. H. Fellows, Detroit Edison Company, Detroit, Mich.

Calculation of Chemicals for Water Softening.

A. M. Buswell, Chief, State Water Survey, Urbana, Ill.

TUESDAY, JUNE 25, 1929

Afternoon Sessions

2:00 Ball Room.

Symposium on Pumping Station Practice:

Selection of Pumping Station Equipment.

Illustrated by Lantern Slides.

A. P. Pigman, American Water Works & Electric Company, New York, N. Y.

Equipment for Electrically Driven Pumping Stations.

R. L. Baldwin, Burns & McDonnell, Consulting Engineers, Kansas City, Mo.

Pump Discharge Headers and Pump Piping for Waterworks Stations.

Illustrated by Lantern Slides.

F. G. Cunningham, Fuller & McClintock, Consulting Engineers, 170 Broadway, New York, N. Y.

Discussion by L. A. Day, Water Commissioner, St. Louis, Mo.

Selection of Equipment for Clove Pumping Station of Staten Island System.

William Flannery, Mechanical Engineer, Department of Water Supply, Gas & Electricity, New York, N. Y.

Comparative Data on Steam and Electrical Pumping Stations.

Illustrated by Lantern Slides.

John F. Laboon, J. N. Chester Engineers, Pittsburgh, Pa.

Conference of Committee No. 19, Boiler Feed Water Studies.

2:00 West Hall.

The Prevention of Pitting in Locomotive Boilers by Exclusion of Dissolved Oxygen from the Feedwater.

C. H. Koyl, Engineer of Water Service, Chicago, Milwaukee, St. Paul & Pacific Railroad Company, Chicago, Ill.

Discussion by R. E. Coughlan, Supervisor of Water Supply, Chicago & Northwestern Ry. Co., Chicago, Ill., and F. N. Speller, National Tube Co., Pittsburgh, Pa.

Railway Water Treatment Progress and Research Requirements.

R. C. Bardwell, Superintendent Water Supply, Chesapeake & Ohio Railway Company, Richmond, Va.

Hydrogen Ion and Conductivity Measurement.

Illustrated by Lantern Slides.

C. Z. Rosecrans, Chief of Chemical Division, Leeds & Northrup Company, 4901 Stenton Ave., Philadelphia, Pa.

2:00 For the Ladies—

Bus tour of city and tea at Royal Canadian Yacht Club—see page 12.

Evening

6:45 Dinner, Water Purification division.

8:00 Ladies' Card Party.

WEDNESDAY, JUNE 26, 1929

9:00 Ball Room.

Business Meeting Canadian Section.

10:00 Ball Room.

General Session—(This session will open one hour later than ordinarily to provide for the business meeting of the Canadian Section and obviate decreased attendance which would otherwise occur if the two meetings were held concurrently.)

Ethics for Engineering Services.

Nicholas S. Hill, Jr., Consulting Engineer, 112 East 19th St., New York, N. Y.

Durability of Distribution Systems.

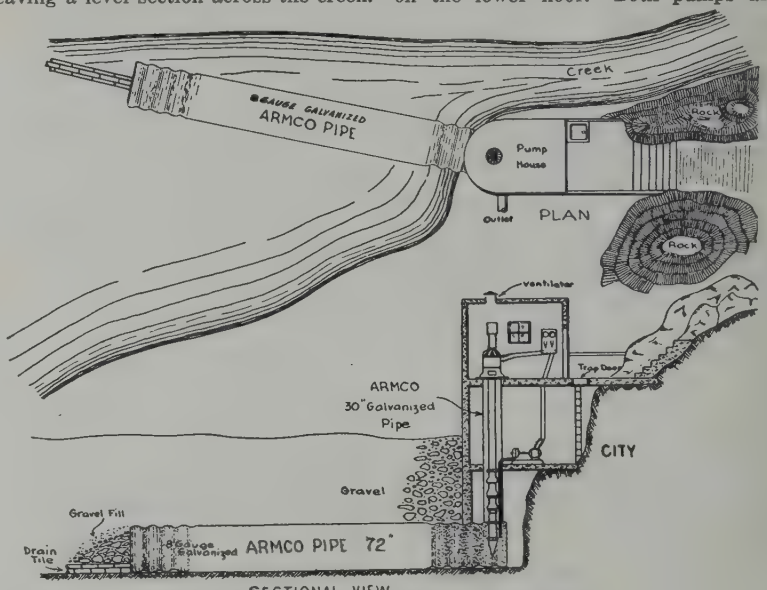
New Well Construction in Prescott

Perforated Corrugated Pipe Infiltration Gallery

By ARTHUR J. KLINE
City Engineer, Prescott, Ariz.

PRESCOTT, ARIZ., a mountain town of 8,000 population has probably as much trouble developing water as any town outside the desert. Fifty-four hundred feet in elevation, surrounded on three sides by mountains and on the fourth by a receding valley it is aptly called the Jewel of the Mountains. All the water passing this town must fall within six miles, and all is carried by Granite Creek running through town and down the valley.

A storage dam in the hills south of town impounds seven months storage and furnishes ample water during the years of normal rainfall, but when no snow nor rain falls for one year this reservoir is empty. Over a period of years by experimenting with cutoff walls, diversion dams, tunnels, side infiltration galleries and wells the water department has tried to use the under ground water of Granite Creek as an emergency supply. In 1928 a successful well was developed. At a narrow point across Granite Creek the gravel was stripped to bedrock with a drag line. The high points were shot off leaving a level section across the creek.



Plan and Section of New Well at Prescott, Ariz.

A 50-ft. section of 72-in. special collection pipe made of No. 8 gauge galvanized corrugated Armco ingot iron fitted with a 30-in. No. 10 gauge galvanized corrugated Armco ingot iron riser was installed. The collection pipe was perforated with ½-in. holes all around in the valley of every corrugation on five-inch centers. This equals 8 sq. ft. of opening. The ends were bulkheaded and from one was run three 6-in. drain tile laterals. The backfill over both tile and collecting pipe was made of 2 ft. of graded rock, then ordinary sand and gravel up to the level of the creek.

The Armco collection pipe was chosen instead of a cutoff wall for the accessibility of the tunnel. During low water when the pump holds the well low a man can decend a ladder in the pump house and walk back through the tunnel to clean out any sand or silt. The pipe has a long life and will apparently last indefinitely. When not pumping the water flows through the well and always shows fresh and clear. During the recent dry period the pump ran 2 hours and was off one hour. A flood 4 ft. deep came down the creek running muddy water from bank to bank. A man sent down to investigate reported that the pump was still running clear water and still shutting off one hour out of three, showing that the water filtered to bedrock some distance from the pump house.

After the first month of pumping the well was cleaned and since then no sand has come through the gravel bed.

A vertical 100 h.p. motor connected to the 600 g.p.m. turbine pump is on the upper floor. A multiple centrifugal pump of 300 g.p.m. capacity is direct connected to a horizontal motor on the lower floor. Both pumps are operated from the same automatic starter and float switch.

The whole layout has been very successful and considering the low cost of installation and lack of maintenance the work stands as good 1928 construction methods.

Street Traffic Survey for Kansas City, Mo.—A street traffic survey for Kansas City, Mo., was started on May 15 under the direction of Dr. Miller McClintock. It is expected the survey will be completed in a year. The estimated cost is $25,000. The survey, which will be city-wide in scope, is being made for the purpose of developing a comprehensive plan for relief from traffic congestion and traffic accidents.

Detroit Voters Defeat Subway Plan.—At a recent election the voters of Detroit rejected the proposal for a subway. The Rapid Transit Commission had recommended that 17 per cent of the total tax be raised by an ad valorem tax on the city at large; 51 per cent on benefited property adjacent to the subway, and 32 per cent to pay for train tracks and other equipment, through a ten-cent subway fare.

Methods of Financing Municipal Improvements

Different Types of Municipal Obligations Classified and Discussed

By HOLLAND M. CASSIDY
Of the Chicago Bar

WHENEVER a municipal improvement is to be constructed it usually involves the borrowing of money because the growing needs of municipalities have consumed revenues as rapidly as, and in many instances more rapidly than funds could be provided. Statutes authorizing the levy of taxes do not contemplate the accumulation of large surpluses which may be used for an improvement to be constructed at some future time. A thrifty community may be found that has carefully protected its treasury, and surpluses exist either by reason of savings in ordinary corporate expenses or profits from the operation of a water works or some other utility, but this is not the usual case. At times legislatures have authorized the levy of a special tax for a specified period for the purpose of constructing some particular improvement such as a courthouse or roads. This method of financing is not satisfactory because the funds come in over a period of years and it is not practical or economical to so extend construction work.

The federal government contributes a portion of the cost of some improvements, particularly road work and levee work, and when such contributions are made the government insists upon either supervision or actual construction of the improvement. In those instances the municipality is sometimes required to turn its money over to the government for expenditures. Experience has demonstrated that the tax payers get their full dollar of value where this procedure is followed.

It is impossible in an article of this type to go into any detail as to the particular procedure for municipal financing since that is governed by the statutory laws of various states, and any consideration of that subject would require a complete detailing of the statutory procedure prescribed by the several states.

In any consideration of municipal financing it is well to have clearly in mind the different types of municipal obligations. A classification of these bonds must group itself on the basis of taxes or revenues to pay the same, from the viewpoint of both the issuing municipality and the purchaser. The following classification and suggestions are submitted:

Unlimited Ad Valorem Tax Bonds.—Principal and interest of these bonds are payable from unlimited ad valorem taxes levied by constitutional mandate at the time the bonds are issued, or for the levy of which mandatory provisions exist, so that all that remains to be done is to extend and collect the tax. This is the best type of municipal bond and the only worry in connection with these bonds is as to the integrity of the community and the probability of its continuance with ample values to support the taxes.

Limited Ad Valorem Tax Bonds.—These bonds are exactly the same as the limited ad valorem tax bonds except that by constitutional or statutory enactment the amount which may be levied in any year to pay principal and interest is limited. In determining the value of these bonds special consideration must be given to the probable amount of taxes which may be realized over the lifetime of the issue from the limited levy, and also as to whether the statute permits the issuance of additional obligations against such tax which will share ratably in the proceeds thereof.

General Obligation Improvement Bonds.—The primary tax to pay these bonds consists of special assessments levied upon benefited property and the obligation requires the municipality to levy ad valorem taxes sufficient to make up deficiencies. This makes a very desirable bond provided the aggregate amount thereof is not disproportionate to the assessed value of taxable property of the municipality; for instance, if the assessed value of the municipality is $2,000,000 and the amount of such bonds outstanding is $2,000,000, patently the bonds are little better than a straight special assessment bond.

Revenue Bonds.—These obligations are payable from excise levies such as water rents, instead of ad valorem taxes, and are usually issued for the purpose of constructing water works or other utilities. Recently an endeavor has been made to add to this type of bond obligations payable from gas taxes and the like. The test applicable to these bonds is the certainty and sufficiency of revenues, together with statutory requirements tending to produce integrity in the application of the revenues and assurance that sinking fund requirements come before operating charges.

Benefit Tax Bonds.—These bonds are payable from taxes to be extended from year to year against benefited property, the aggregate amount of which benefits is fixed. This type of bond is usually issued by irrigation districts and some of the western drainage districts.

Special Assessment Bonds.—These are bonds payable from special assessments levied in a specified amount upon particular properties benefited from local improvement work. These bonds constitute desirable securities if the property values are sufficient to support the special assessment liens and the amount of assessments available to pay the bonds is ample to retire the issue.

Tax Bills.—These obligations are issued by the municipality against particular pieces of property on account of benefits derived from the construction of a local improvement. They are in odd amounts and are a lien only upon particular pieces of property. Of course the value of each depends upon the value of the property against which it is issued. The great objection to this type of security is its marketability. The most successful mode of handling this type of paper has been to deposit the tax bills with a trust company and issue debentures or participating certificates against the proceeds of the aggregate deposit.

Bonds Payable from Taxes to Be Levied.—This type of bond is rapidly disappearing. Its weakness is the possibility that the local officials will fail to levy the necessary taxes in a particular year. This weakness is more theoretical than real. The good faith of the community usually prompts the performance of the necessary acts. Many government obligations are subject to this criticism.

Temporary Borrowing.—These obligations are issued in anticipation of permanent financing or in anticipation of the collection of ordinary annual operating taxes.

General Discussion

Ad valorem taxes are levied upon the basis of value against all of the taxable property in the municipality.

Benefit taxes or special assessments are enforced contributions from land owners for enhancement of value received by particular properties on account of the construction of a local improvement; for example, a pavement in front of property increases the market value of that property and the benefit tax is levied on account of this increase.

Excise taxes are levies made upon commodities and from an entirely distinct basis of taxation from either of the two foregoing methods. The most

Editors Note: The author of this article specializes in municipal bond law.

conspicuous in this class of taxes so far as municipal bonds are concerned at the present time are water and other utility revenues. There is a growing tendency to issue bonds in anticipation of the collection of these revenues. It is probably safe to anticipate that this type of revenue is as certain as property value. The consumption of water in a given community is probably dependent upon practically identically the same elements as those which produce value to property, to wit, population and industry. Whether gasoline taxes, license fees and the like are sufficiently stable to warrant their anticipation by long-time obligations may be open to some argument.

Improvements may be constructed by the use of more than one type of financing. Some municipalities may construct a water works improvement by the use of ad valorem tax bonds which constitute an unlimited obligation of the entire municipality, by the use of special assessments levied upon benefited property, or by revenue bonds which will be payable only out of revenues to be derived from the completed improvement. Which of these methods should be used is for the determination of the corporate authorities. The factors which should influence their decision are the cheapest net cost of the improvement and the conservation of the debt incurring power of the municipality for other needed improvements which must be paid for by the full faith and credit obligations of the municipality.

A particular type of security in a given state may be in bad repute due to defects in the law authorizing the issuance or otherwise. As far as possible municipalities should avoid the use of any type of security which is thus depreciated. It is always desirable to issue the most marketable type of security in order that the best price may be obtainable therefor and the net cost of the improvement reduced.

A particular improvement may be constructed by a contractor who will take in payment bonds issued therefor, but if it is patent that a small percentage of the par value of bonds actually goes into the construction of the improvement, then it is most unwise to proceed. There is no way to establish an arbitrary percentage of the par value of obligations which should represent cost of labor, material and reasonable contractor's profits, but certainly if less than 75 per cent of the par value of the bonds actually goes into labor, material and reasonable contractor's profits, the municipality should seriously consider deferring the construction of that improvement.

Factors Affecting Value of Bonds.—The value of municipal bonds and the reputation of the issuing municipality would be aided if the corporate authorities seriously considered the necessity of a contemplated improvement and ordered its construction only when it is patent that the improvement is necessary and that the type and design selected are adequate for the needs but are not extravagant. Certainly the construction of a schoolhouse, city hall or any other improvement far in excess of needs, either as to size or elaborateness, affects the price which may be obtained for that issue, and may ultimately affect the credit of the municipality. It also imposes an unreasonable burden upon the tax payers. To avoid these excesses many states have imposed limits upon the amount of indebtedness which the municipality may incur.

Other important factors in the value of municipal bonds are the time and manner of payment. There is a well developed tendency to so arrange the maturities of the bonds that the issue will be fully paid before the usefulness of the improvement is exhausted, and to make the principal payable in instalments over a period of years. This requires the tax payers using the improvement to pay for it and avoids the necessity of accumulating sinking funds.

The experience with sinking funds has not been entirely satisfactory. Sometimes the sinking fund is misappropriated or lost, and sometimes it is not even collected. If it is collected it is impossible to invest the sinking fund in desirable securities which will produce interest at as large a rate as that being paid on outstanding bonds; consequently it is preferable to so arrange the maturities of the bonds that the amount of taxes paid annually on account of said bonds will be about the same each year.

In conclusion it is submitted that in the financing of any municipal improvement effort should be made to issue that type of obligation which will provide the cheapest financing, constitute a reasonable tax burden and not embarrass the municipality in its ordinary operations or in its future developments and will be fully paid within the lifetime of the improvement.

Care should be taken to see that all proper safeguards are provided in the law authorizing the issuance so as to encourage purchasers and thus give a broader market for the securities. These safeguards must consist of two elements: (1) Provisions encouraging and enforcing integrity of municipal officials in the administration of the funds and the prompt collection and application of taxes for the payment of obligations, and (2) The most liberal requirements with respect to the amount and certainty of collection of taxes sufficient to pay maturing principal and interest. As to the value of a particular security, the reputation of the issuing body, its population, value and relationship between indebtedness and value and limitations affecting the amount of indebtedness must all be considered.

Methods of Financing Constantly Changing.—It must be remembered that modes of financing are continually changing. Municipalities should readily avail of all new and improved methods of financing which will add value; for instance, where there are overlapping taxing districts a coordination of their financing will prevent overloading the market and thus increase the sale value of their securities. When it becomes advantageous to finance a particular type of improvement such as road construction from the sale of securities payable from gas taxes and license fees, that method should be adopted, particularly in those communities where the burden of taxation to pay general obligation bonds affects land values.

A contractor or municipal official would do well to employ competent counsel to explain fully the operation of any existing law under which it is proposed to construct an improvement so that he may know exactly where he stands before contracts are made.

Municipal Golf Courses in New York State

According to the City Record, the official publication of the city of Boston, Mass., five cities in New York State operate municipal golf courses. New York City has six courses; Buffalo has four; Rochester has three; Syracuse has two, and Niagara Falls one. Ten of these sixteen courses have eighteen holes and six have nine holes. The sizes of the eighteen-hole courses range from 72 to 305 acres, and for the nine-hole courses from 30 to 79 acres. The 1927 cost of maintaining the six courses in New York City was approximately $100,000; the revenues from fees, lockers and concessions for the golf season was about $212,000. The cost of maintaining the three courses in Buffalo for 1927 was $45,000 and the revenues $30,000; in Rochester the three courses cost $19,690 to maintain and produced a revenue of $39,126; the two courses in Syracuse cost $3,631, with a revenue of $10,375; and the cost of maintaining the course in Niagara Falls was $15,000, with a revenue of $13,000. The number of persons using the New York City links was about 272,000; the Buffalo links, 30,000; the Rochester links, 118,890; and the Niagara Falls links, 29,375.

The fees charged for use of links in New York City were $10 a season or $1 a day; in Buffalo 50 ct. per round on three of the courses, and $25 a year, or 50 ct. a round, on the other course; in Rochester $7.50 a season or $1 per day; in Syracuse 35 ct. on week days, 50 ct. on Sundays and holidays; in Niagara Falls $10 a season or 50 ct. a day. In New York City a locker charge of $10 to $20 is made, and in Buffalo a charge $5 per year for lockers. All these cities have clubhouses, except Niagara Falls, and New York, Buffalo and Syracuse have showers.

Natural Basins Flooded to Increase Flow of Supply Wells

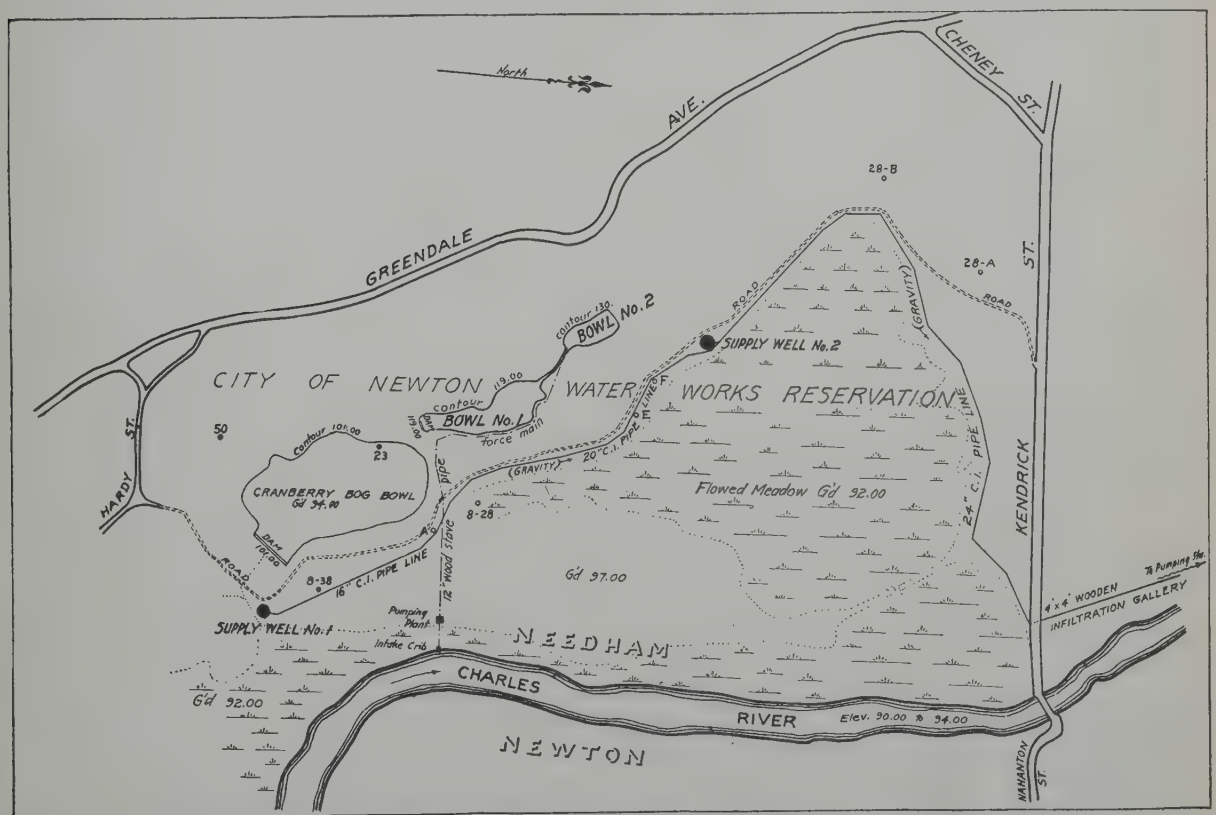
Newton, Mass., Adds to Water Supply by Ingenious Method

DURING the year 1928 the city of Newton, Mass., was confronted with the problem of securing an additional water supply. The water supply of the city is obtained largely from two large concrete supply wells situated in the meadows on the westerly side of the Charles River. These wells intercept the ground water which flows from the higher lands to the west toward the lower levels of the Charles River valley and deliver it to the city mains. The presence of certain natural bowls or basins in the higher land just west of the wells suggested the possibility of increasing the flow of the wells by flooding the basins with water from the Charles River.

Natural Reservoirs Suggested.—Many borings and excavations conducted in the area occupied by the basins indicated that the underlying strata were composed of gravel and sand of such a texture as to furnish ready communication between the surface and the levels reached by the wells. This conclusion was confirmed by the rapidity with which surface water in the basins was observed to drain away into the ground. Thus it was anticipated that the scheme of filling the bowls with river water would be successful. The expense would not be great, as it would be necessary only to locate the basins to be used far enough from the wells to assure proper filtration and to remove surface materials and the top layers of soil. It was thought also that the quality of the supply pumped from the wells would be improved by the addition of the soft river water to the somewhat harder ground water. Again, it was considered that the action of air and sunlight upon the stored water would aid considerably in its purification. The additional storage capacity secured would not be limited to the volume of the basins flooded, but would consist also of the very appreciable capacity of the ground beneath the bowls.

Scheme Applied on Experimental Scale.—The accompanying map of the Newton water-works reservation shows the layout of river, wells and natural basins. It was decided to experiment first with the basin known as Bowl No. 1. This bowl is situated about 1,200 ft. back from the Charles River. The underlying strata of sand and gravel were covered with a layer of loam varying in depth from 2 to 5 ft., and it was first necessary to strip this soil. Accordingly an area 40 ft. wide and 700 ft. long in the bottom of the bowl was uncovered. The material was removed by a steam shovel and cast to the side of the trench so that it might be removed later if it was decided to carry the work beyond the experimental stage. This work, which involved the handling of 5,000 cu. yd. of material, was done for a contract price of $1,000.

A pump well was installed at the river and a line of 12-in. wood stave pipe was laid to the bowl. Pumping equipment consisted of an 8-in. centrifugal pump driven by a 20-hp. motor



Needham Water Works Reservation, City of Newton, Mass., Showing the Two Supply Wells, the Two Bowls and the Supply Line Leading from the Charles River

and capable of pumping approximately 1,400,000 gal. per day against a head of 50 ft. The pipe line, which had a total length of 950 ft., was laid at a total cost for labor and materials of about $2 per ft.

Flow Increased Appreciably.—Pumping of the river water was begun on Feb. 16 and, beginning with this date, the daily output of each of the supply wells was carefully measured. In addition, numerous tube wells were observed to determine the effect of flooding the bowl upon the level of the ground water. On Feb. 18 an increase in the flow of the supply wells was noticed, and it was observed that the ground water had begun to rise in the tube wells. The normal output of Well No. 1, as determined before the experimental flooding of the bowl, was about 800,000 gal. per day. The output of Well No. 2 was about 1,160,000 gal. per day. After ten days of pumping water into the bowl, an increase of 230,000 gal. per day in the output of Well No. 1 was noted, while the increase shown by Well No. 2 was about 550,000 gal. per day. Thus the total increase in the supply furnished by the two wells was about 40 per cent. During this period, the rate of flow into the bowl was 1,400,000 gal. per day. The increase of 780,000 gal. per day in the flow of the two wells gives a recovery of water pumped of about 56 per cent. Analyses of samples of the water showed a satisfactory quality. The experiment was deemed successful, and preparations were made to continue with the excavation and flooding.

Second Basin Stripped.—Excavation of the remainder of Bowl No. 1 was begun in July and completed in the fall. This bowl has a capacity of 6,000,000 gal. when filled to El. 119, and at this level the water covers an area of about 1.8 acres. Bowl No. 2, excavated at the same time, is much smaller, having a capacity of about 1,500,000 gal. when filled to El. 130. The area covered at this elevation of water is about 0.65 acres. Comparison of the added daily flow of the wells with the capacity of the bowls gives an idea of the rapidity with which the water drains away through the porous strata below the surface. About 14,500 cu. yd. of surface material were stripped from the two bowls at a cost of $9,500.

The total length of wood stave pipe line supplying the two bowls is now 1,730 ft. A concrete intake crib is being constructed at the river. A 24-in. vitrified pipe line leads to a pump well situated about 150 ft. back from the river bank. New pumping equipment consists of a 10-in. centrifugal pump, driven by a 50-hp. motor. This pump can deliver 3,500,000 gal. per day against a head of 60 ft.

Observations at the tube well marked 8-28 on the map showed that a large portion of the water not recovered by the two supply wells came to the surface in this vicinity, indicating that this would be a favorable site for a third supply well.

Contracts for stripping the bowls were executed by the John MacDonald Construction Co. The pipe line and pumping equipment were installed by the city water department. E. H. Harvey, designing engineer with the engineering department of the city, was in charge of the work. George A. Sampson, of Western & Sampson, Boston, Mass., is consulting engineer. W. P. Morse is city engineer of Newton.

Soft Water in the Dakota Sandstone

The geologic formation known as the Dakota sandstone, which underlies most of South Dakota and large parts of several other states, is well known for the thousands of flowing wells which it supplies and for the great artesian pressure that was formerly exerted on the water in these wells. The strongest well originally had pressures ranging from 100 to more than 200 lb. to the square inch and would throw up jets of water to heights of 100 ft. or more. Many of the wells that tap this sandstone are still flowing but with greatly reduced pressure, and some have ceased to flow.

Hard and Soft Water in Same Sandstone.—The Dakota sandstone is remarkable not only for the artesian pressure of its water but also for the variety of water that it contains, some of the water being very hard and some very soft. As a rule the upper strata contain soft water, and the lower strata contain hard water. In some places, as at Canton, South Dakota, and in large parts of western Minnesota, the Dakota sandstone rests on the irregular ancient land surface of hard pre-Cambrian rocks such as quartzite or granite. In some of these places the lower part of the formation is absent, and only the upper soft-water strata are encountered in drilling.

The hard water is generally very hard and otherwise highly mineralized, so that it is very unsatisfactory for washing or for use in steam boilers. Much of it is also unsatisfactory for drinking and cooking, but it is generally used for irrigating lawns and gardens. Some of the soft water is of good quality, being not only excellent for washing but also satisfactory for drinking and cooking, use in steam boilers, and irrigation. Much of the soft water, however, contains so much common salt and soda that it is disagreeable to the taste and deadly to vegetation and causes foaming when used in steam boilers. All of the water, both hard and soft, is considered especially desirable for live-stock supplies. The dissolved salts are apparently not unwholesome to the domestic animals, and the relatively high temperature of the water, which comes from great depths, makes it especially attractive and beneficial to them during the long cold winters.

Soft Water for Tub Night and Wash Day; Hard Water Rest of Week.—Some interesting local problems are created by this variety in the quality of the water. For example, at Ellendale, N. D., both hard and soft water were formerly supplied by the city waterworks. From Saturday night to Monday night the smaller supply of soft but rather salty water from the upper part of the Dakota sandstone was pumped into the system to furnish water for toilet and laundry uses, but later in the week the hard water from the deepest well was pumped into the system and was used for sprinkling lawns and irrigating gardens.

The experience at Canton, S. D., affords an example of a somewhat different problem. Here adequate quantities of hard water have for many years been pumped from shallow dug wells in gravel deposits for the city supply and the Government asylum. It was known, however, that soft water, satisfactory for every use, occurs in the Dakota sandstone at a depth of about 300 ft., and wells were drilled to recover this desirable supply. Unfortunately, the sandstone at this place, as in many other localities, is so fine grained and incoherent that the wells give trouble when they are heavily pumped, and it is difficult to recover large supplies.

Water Supply Problems Studied by Government.—The problems of the Dakota sandstone and of other water-bearing formations in the region in which it exists have been given much study by the Geological Survey of the United States Department of the Interior as to the quality of the water, decline of artesian pressure, methods of preventing waste, and methods of finishing wells so as to obtain large supplies without pumping sand. Recently a study was made of the problems at Canton, South Dakota, especially in regard to the Government water supply, and a brief report (Water-Supply Paper 597-C), prepared by O. E. Meinzer, has been published in which the studies at Canton are applied to the general problems of the Dakota sandstone. The report presents data as to the occurrence of soft water in an area where its existence has not until recently been known and calls attention to the possibilities of finding it in other localities in this general region in which at present only hard water is obtained. It presents, almost for the first time in hydrologic literature, detailed information as to the performance of wells in a sand whose physical and hydrologic properties were determined in the laboratory. It was prepared especially for the information of the water-well drillers of the Northwest in improving the water supplies of that region. The author considers the drillers his colaborers, for they have contributed generously to this and other investigations.

Court Decisions on Sanitary Matters

Recent Rulings of State Courts

MUNICIPALITIES Held Liable for Nuisance Caused by Sewer and Sewage Disposal Plant.—(New Jersey Court of Errors and Appeals; Ennever et ux. v. Borough of Bergenfield et al., 144 A. 809; decided Feb. 14, 1929.) An action was brought against certain municipal corporations to recover damages for injuries to plaintiff's property, resulting from the construction and operation by the defendants of a joint sewage-disposal plant and a joint sewage system. A jury found that the disposal by the municipalities of sewage into a small stream which flowed through plaintiff's land created a nuisance, and returned a verdict for the plaintiffs. The court of errors and appeals affirmed the judgment of the lower court, basing the liability of the defendants on the fact that, although they "were performing a public duty in constructing and operating the sewers and the disposal plant," they "were committing an active wrong, thereby causing special damage to the plaintiff's property."—Public Health News, April 26, 1929.

Construction of Statute Concerning Disposal of Dead Animals.—(Iowa Supreme Court; State v. Redlinger, 224 N. W. 83; decided March 12, 1929.) Section 2761, Code 1924, provided as follows:

> No person caring for or owning any animal that has died shall allow the carcass to lie about his premises. Such carcass shall be disposed of within 24 hours after death * * *.

By section 2762 a violation of the above section was made punishable by fine or imprisonment.

In a prosecution under the statute the defendant argued that the indictment charged more than one offense. In passing on this claim the supreme court had the following to say regarding its interpretation of the enactment:

> * * * Plainly the law is violated when the person caring for "any animal that has died" allows "the carcass to lie about his premises" for 24 hours without disposing of it as required. Thereby such person subjects himself to the penalty prescribed by section 2762. At the end of the 24 hours the offense is complete. * * * It was not intended to inflict a penalty for permitting a dead animal to remain uncared for for an hour or 10 hours but for 24 hours. * * *—Public Health News, May 3, 1929.

Authority of State Department of Health Sustained in Stream Pollution Case.—Authority of the Ohio State Department of Health to prevent stream pollution by order to a municipality that it cease the discharge of sewage into a stream was sustained by the full bench of the Ohio Supreme Court in a decision handed down April 24, 1929, in a case brought against the Department by the city of Bucyrus. The opinion was written by Judge Robinson.

This is a case (City of Bucyrus vs. Department of Health) wherein the city of Bucyrus contested the authority of the Department of Health to issue an order requiring the city to cease the pollution of the Sandusky river by the discharge of sewage into that stream. The order of the Department of Health was made Dec. 14, 1928, and this action was filed in the Supreme Court within the time limit fixed by statute. The petition of the plaintiff set forth many points on which error was claimed in the proceedings of the Director of Health and the Public Health Council, including the following:

> That as no complaint in compliance with Sec. 1249 G. C. had been filed with or presented to the Department of Health, the Director was without right or authority to make his finding.
>
> That sufficient evidence was not presented to sustain the finding and its approval, and the determination of the Public Health Council that the city be required to make certain changes and improvements; but that they were contrary to law, unlawful and unreasonable.
>
> That there was not sufficient evidence to sustain the order of the Director and its approval, and that they were unlawful and unreasonable.
>
> That there was error by the Council in proceeding over the protest of the city of Bucyrus; that it acted without sufficient evidence before it; that it considered matters outside the record, and that it refused to require proof as to sufficiency of the complaint on which the Director acted.
>
> That the sections of the Code under which the Director acted are unconstitutional, null and void, as being in conflict with the constitutions of both State and Nation.
>
> That the act of the General Assembly, passed April 7, 1908, entitled "An Act to authorize the State Board of Health to require the purification of sewerage and public water supplies and to protect the streams against pollution," with its amendments, so far as it relates to matters other than public water supplies, is not an enactment to protect the public health; is not an exercise of the police power of the State, and confers no jurisdiction on the Department of Health in this proceeding.
>
> That all the acts and orders of the Department of Health, the Director of Health and Public Health Council were made in violation of evidence, in an ex parte, summary and arbitrary manner, apparently under the influence of passion and prejudice, and therefore were unlawful and unreasonable.
>
> That due process of law was denied the plaintiff in error.

All these objections were brushed aside in the decision of the Court, which declared in specific terms that the so-called "Home Rule" amendment to the Constitution in no way curtails the sovereignty to the State over Municipalities in respect to sanitation for the promotion or preservation of the public health. The approved syllabus of the decision of the Supreme Court is as follows:

1—The provisions of Article XVIII of the Constitution of Ohio do not deprive the State of any sovereignty over municipalities in respect to sanitation for the promotion or preservation of the public health which it elects to exercise by general laws.

2—The holdings of this Court in the case of State Board of Health v. Greenville (86 Ohio St., 1), are as applicable to municipalities since the adoption of Article XVIII as they were before the adoption of that Article, and will be adhered to.

3—The report of an investigation required by Section 1249, General Code, is competent evidence at a hearing provided for in Section 1250, General Code, but is not conclusive, and the persons securing the data are subject to cross-examination and impeachment.

Opinion written by Judge Robinson, and concurred in by Marshall, C. J. Kinkade, Jones Matthias, Day and Allen, JJ.

On the same day the Supreme Court overruled the demurrer of the city of Delphos to a petition by the Department of Health for a writ mandamus to compel that city to comply with an order of the Department requiring the city to make certain changes and improvements in its methods of handling sewage, for the prevention of stream pollution. Grounds of the demurrer by the counsel for the city of Delphos were substantially the same as the basis of argument by counsel for the city of Bucyrus.—Ohio Health News, May 1, 1929.

Keeping of Swine and Dumping or Leaving Garbage in Town Restrained. — (Massachusetts Supreme Judicial Court; Inhabitants of Swansea v. Pivo, 164 N. E. 390; decided January 5, 1929.) The board of health of the town of Swansea adopted the following regulations:

> No person, firm or corporation shall keep or maintain within the limits of the town six or more swine over 3 months of age without a permit from the board of health.
>
> No person, firm or corporation shall deposit, dump or leave within the limits of the town any swill or garbage without a permit from the board of health and in such case in no place other than that fixed by the board and described in such permit. * * *

Thereafter the defendant kept a large number of swine in the town without a permit from the board of health and in violation of the regulations. The board of health, acting under statutory authority, then directed the issuance of an order of prohibition against the defendant, having already determined that the keeping of swine and the dumping or leaving of garbage by the defendant was dangerous to the public health and a nuisance. The defendant failed to obey the order and suit was brought by the town to restrain him. A decree, entered in favor of the town, was affirmed by the supreme court. Points determined by the appellate court are set forth in the quotations from the opinion, which follow:

> The [master's] report discloses, it was admitted by the plaintiff, that the records of the meeting held on July 8, 1927, when the regulations were adopted, and the records of the meeting of November 21, 1927, when the order of prohibition was voted, were amended by the clerk of the board of health the latter part of November or the first part of December, 1927, and that the amended records were signed by the clerk of the board. The master further found that "the amended records, * * * in evidence, are a true record of what took place at the meetings named." The records as amended plainly show that the regulations and order of prohibition were duly adopted. The clerk had power to amend his original records to conform to the truth. The amendments thus made became a part of the record and the whole record is to be considered as such. * * *
>
> The town may maintain a suit in equity to enforce regulations adopted by its board of health, under the provisions of G. L. c. 111, sections 31, 122, 143; * * * As the original

records were inaccurate and defective, it was within the power and was the duty of the clerk to amend them. It could be shown by a member of the board that the amended records were accurate. * * *

The defendant made an offer to prove that the board of health acted in bad faith in issuing the order of prohibition, and offered to show that the acts complained of did not constitute a nuisance and were not injurious to health. This evidence was rightly excluded. The proffered proof is not admissible in these proceedings. * * *

"The determination of the board of health is not a merely ministerial act; but is quasi judicial, in the sense that it is not to be contested or revised, except in the manner provided in the statute. * * *"

* * * It does not appear that any special authorization to continue the trade or employment pending this suit was given under G. L. c. 111, sec. 148.—Public Health News, March 15, 1929.

Sprinkler System for Curing Concrete Pavements

The accompanying photographs illustrate the scheme employed by W. F. Pigg & Son, Inc., contractors, Denver, Col., for curing concrete on their city paving jobs. By the adoption of this system, concrete curing costs are stated to have been cut to less than one-half the cost of puddling or sprinkling with hoses.

A 2-in. pipe line is placed down the center of the pavement, where the width is 25 ft. or less. For greater widths, two or more lines are used. Sprinkler heads are installed approximately every 20 ft. Where a fire hydrant is available, the pipe line is connected to the plug; in a section where there are no hydrants, it is necessary to use a force pump. With one fire hydrant working at a pressure of approximately 60 lb. per sq. in., it is possible to cure a section 25 ft. wide and approximately 1,000 ft. long. For larger areas, more plugs may be connected in. The sprinklers are operated only intermittently, the water being turned on for a period of about one minute every 10 to 15 minutes. The sprinkling period is, of course, variable —more water being required on hot days and less on cloudy days.

Consumption of water and the cost of labor are both much less where this method is used in preference to covering the pavement with moist earth or building earth dikes and flooding the surface, the contractors state. A boy, or a laborer paid a small wage, can handle an enormous section of finished pavement.

A patent on this method of curing pavements is pending.

One of the Sprinkler Heads

Curing a Concrete Pavement by Sprinkling

Monterey's Municipal Rose Garden

By FRANCIS E. LESTER

President, Monterey Chamber of Commerce

The municipal rose garden in Monterey, Calif., is just now in its fullest glory. More than 1,200 rose bushes are in bloom and the planting plan, which produces the maximum of mass color effects, displays these blooming bushes to the greatest advantage.

Visitors are found in the garden daily from many remote points; during a recent week, visitors to the garden included groups from Seattle, San Diego and Denver.

The garden was started by the city of Monterey a year ago, when a small part of the planting was done; but most of the roses have been planted this spring. The garden contains about 1,400 roses—more than 200 varieties of bush roses, over 60 varieties of climbing roses, 20 varieties of pillar roses and about an equal variety of standard or tree roses. Some of these latter are budded with three harmonizing colors on the stem.

A lily pool is in the center of the garden, ringed around by tree and baby roses. Surrounding this central feature are the mass plantings of red, pink, yellow, and new-bud roses. One beautiful bed contains fifty of the new single Vesuvius rose, a deep flaming scarlet, which is now in full bloom.

A unique feature of Monterey's municipal rose garden is that it is within two blocks of the business center of the town. It adjoins historic Colton Hall, first state capitol of California, and on all sides of the garden the visitor encounters historic landmarks such as the residence of General Fremont in 1847; the residence of Governor Alvarado; the "House of the Four Winds," and the former home of Thomas Larkin, first American consul.

In one of the most interesting spots in the garden is the planting, in adjoining beds, of the old and the new roses. Among the old roses are found examples of many roses no longer in commerce, originations of centuries ago, such as the York and Lancaster, the old Blush and several varieties of the Old Norse Roses. Oldest of all, and perhaps most interesting, are the two bushes of what is known as the Ancient Rose—identically the same rose that grew in the days of Greece and Rome. Immediately across the walk are examples of the very latest and finest roses, thus illustrating what the rose hybridist has accomplished in the development of the present-day rose of such exquisite form and marvelous coloring. In one corner of the garden are found plants of the species of parent roses, from which all hybrid roses have been created. Another corner is planted with the sweetbriers; another with the Austrian briers which gave to the hybridist the yellow tones found in the modern rose.

In one corner is a rose found in no other municipal rose garden in the world—the Father Junipero Serra Rose, created by Rev. Father Schoener of Santa Barbara and presented to Monterey's Municipal Rose Garden. There are many other interesting features of the garden to be found by the visitor.

Everything in the Monterey municipal rose garden is plainly marked with the name and date of origin. The beds are so arranged that every rose is easily seen from an adjoining walk or pathway.

The main approach to the garden is underneath a series of twelve arches, each arch planted with two similar climbing roses. Among these are found examples of the old roses of Monterey, including the famous Sherman Rose and other old roses no longer in commerce.

The financing of the garden and its perpetual maintenance are provided for by the city government, and the great number of people who have visited it in the past few weeks is a striking indication of their appreciation of the vision and foresight of the city authorities in providing for Monterey this, its chief beauty spot.

Taxes Paid Through Banks.—A new tax collection plan is now in force at Baltimore, Md., which allows payment of taxes through neighborhood banks.

Design of Sprinkling Filter Distribution Systems

A System for Calculating Pipe Sizes

By ANSELMO F. DAPPERT and W. H. WISELY
Assistant Sanitary Engineers, State Department of Public Health, Springfield, Ill.

FOR convenience in checking plans and to simplify the process of calculating pipe sizes for the distribution system which ordinarily involves laborious trial and error methods, we have developed a system which we believe to be positive and which eliminates most of the usual required assumptions.

In the formulas which we have developed there is only one item for which we need to apologize and that is the assumption that the friction coefficient for the same diameter pipe and the velocities which ordinarily prevail in a distribution system, are constant. This assumption is not quite true but from several detailed calculations we have shown it to be satisfactory for all practical purposes.

Under the usual assumption that there is no variation in the quantity of liquid supplied to the various nozzles and laterals, the loss due to entrance into any lateral or nozzle riser is the same as for any other lateral or nozzle riser. This being accepted, the maximum loss of head will occur in the nozzle farthest removed from the dosing tank. To be on the safe side it is customary to provide that the total loss of head calculated from the farthest removed nozzle to the dosing tank shall not be more than the total loss allotted to the distribution system.

The actual total loss in a distribution system can therefore be laboriously determined by calculating the frictional losses in each section of the lateral between nozzles, in each section of the main between laterals, in the section of main between the filter bed and siphon, the entrance losses into one lateral and one nozzle riser, and taking their sum. The losses through reducers are negligible.

In a main or lateral of uniform diameter, there is a certain equivalent quantity which if flowing throughout the entire length of main or lateral will produce a frictional loss of head equal to the sum of the actual frictional losses in each section of the main between laterals or in each section of a lateral between nozzles. The same is true for any section of a compound main or lateral. The problem therefore, is to determine the above equivalent quantity.

Two General Cases.—There are two general cases as follows:

(A) A main with two-way laterals. (Note that we designate a lateral as any pipe which supports nozzles and projects laterally from the main.)

(B) A main with one-way laterals or a lateral supporting a single row of nozzles.

Without going into the derivation of our formulas but with the statement that we can furnish any one interested in the subject with the proof we will state that

$$(1)\quad X = \frac{2\,(2^2+4^2+6^2\ldots+N^2)}{N}$$

(For main with two-way laterals.)

$$(2)\quad Y = \frac{1^2+2^2+3^2\ldots.+N^2}{N}$$

(For main with one-way laterals, or a lateral.)

where X = the number by which the discharge for one lateral should be multiplied to ascertain the equivalent quantity flowing in a main with two-way laterals.

Y = the number by which the discharge for one lateral (or one nozzle as the case may be), should be multiplied to ascertain the equivalent quantity flowing in a main with one way laterals, (or in a lateral, as the case may be).

N = the number of laterals (or in Equation 2, the number of laterals or the number of nozzles as the case may be).

In a compound main serving 2-way laterals, equivalent quantities flowing must be determined for each separate section of the compound main. Where x_1 x_2 etc. = the number by which the discharge for one lateral should be multiplied to ascertain this equivalent quantity flowing in the largest, next to the largest, etc. section of the main, and N_1, N_2, N_3, etc. = the total number of laterals in the bed, the total number of laterals less the number of laterals tributary to the largest section, the total number of laterals less the number of laterals tributary to the largest and next to the largest sections, etc., X_1 X_2 etc. should be substituted for X and N_1, N_2, etc. substituted for N in Formula No. 1.

In a compound main serving one way laterals or in a compound lateral, equivalent quantities flowing must be determined for each separate section of the main or lateral and in formula No. 2, Y_1 Y_2 etc. should be substituted for Y and N_1, N_2, etc. substituted for N.

Values for X and Y.—Tables I and II have been prepared giving values of X and Y for various values of N as computed from Formulas Nos. (1) and (2).

The use of the above tables will be made clear by the following examples, in which a cast-iron pipe nomograph has been used for determining pipe diameters and head losses.

Use of Tables—Example I.—A filter has been designed up to the point of determining pipe sizes and the following data are established:

(a) Allotted loss for distribution system = 0.5 ft.
(b) Size siphon = 24 in.
(c) Main with 24 laterals (2-way) spaced at 8.5 ft.
(d) Distance from siphon to a point 8.5 ft. from first pair of laterals = 30 ft.
(e) Equivalent of 10 full ⅞ in. Taylor circular nozzles on 2 in. risers spaced at 9.83 ft.
(f) Discharge for one nozzle at maximum net head = 17 g.p.m.

1. The siphon size (24 in.) will be carried to a point 8.5 ft. from first pair of laterals. Loss in 30 ft. of 24 in. flowing $17 \times 10 \times 24 = 4080$ g.p.m. is 0.042 ft. We now have $0.5 - 0.042 = 0.458$ ft. as the allotted loss in the remainder of the distribution system.

2. For economical design we will allot about 75 per cent of the loss to the laterals and the remainder to the main. On this basis we will allot $0.25 \times 0.458 = 0.1145$ ft. loss to the main

$$= \frac{0.1145 \times 100}{12 \times 8.5} = 0.112 \text{ ft.}$$

per 100 ft.

3. From Table I for $N = 24$, $X = 14.7$
$14.7 \times 10 \times 17$ = equivalent quantity = 2500 g.p.m.

4. For a loss of 0.112 ft. per 100 ft. and a flow of 2500 g.p.m. a 21 in. main is required. The nearest commercial size is 20 in., so we will make the main of a uniform diameter of 20 in. from a point 8.5 ft. from the first pair of laterals, putting in a reducer at the designated point.

5. The loss in $12 \times 8.5 = 102$ ft. of

Table I. (For main with two-way laterals)

N=	4	6	8	10	12	14	16	18	20	22	24	26	28	30
X=	3.16	4.31	5.48	6.64	7.79	8.85	10.1	11.3	12.4	13.6	14.7	15.9	17.0	18.2

Table II. (For main with one-way laterals, or a lateral)

N=	3	4	5	6	7	8	9	10	11	12	13	14	15
Y=	2.16	2.74	3.32	3.88	4.47	5.0	5.58	6.16	6.75	7.32	7.90	8.50	90.7

20 in. main flowing 2500 g.p.m. = 0.143 ft. We now have 0.458 — 0.143 = 0.315 ft. as the loss to be allotted to the lateral including the entrance losses to lateral and nozzle riser. Ordinarily these two entrance losses will amount to less than 0.1 ft. so we have 0.315 —

$$0.1 = 0.215 \text{ ft.} = \frac{0.215 \times 100}{10 \times 9.83} = 0.219 \text{ ft.}$$

per 100 ft. as the frictional loss to be allotted to the lateral.

6. From Table II for N = 10, Y = 6.16.

6.16 × 17 = equivalent quantity = 105 g.p.m.

7. For a loss of 0.219 ft. per 100 ft. and a flow of 105 g.p.m.; a 5.8 in. lateral is required. Therefore we will use 6 in. laterals.

8. Our layout now comprises a 24 in. main extending from the siphon to a point 8.5 ft. from the first pair of laterals, a 20 in. uniform main in the bed, and 6 in. uniform laterals. We should now check the actual losses to be certain that the calculated losses for the system conform to the allotted losses.

Entrance loss to nozzle riser	= 0.024 ft.
Entrance loss to lateral	= 0.030 ft.
Loss through reducer neglected	= 0.000 ft.
Loss in 30 ft. of 24 in. Main	= 0.042 ft.
Loss in 102 ft. of 20 in. Main	= 0.143 ft.
Loss in 98.3 ft. of 6 in. lateral	= 0.170 ft.
Actual total distribution system loss	= 0.409 ft.
Allotted distribution system loss	= 0.500 ft. O.K.

The same actual total distribution system loss can be obtained by taking the sum of the two entrance losses, the separate losses in each section of the main between laterals and in each section of the lateral between nozzles, and the loss in the main between the siphon and the bed, but this is a laborious process which the system we propose avoids.

To illustrate the use of the above tables in connection with a compound main or lateral we will take the data in Example No. I and design a compound main so that the total loss in the main will be equal to the loss allotted to the main.

Use of Tables—Example No. II.—The 24 in. will be carried as in Example No. I, to a point 8.5 ft. from the first pair of laterals.

Allotted loss to the main = 0.1145 ft. = 0.112 ft. per 100 ft.

1. N_1 = total number of laterals = 24. From Table I for $N_1 = 24$, $X_1 = 14.7$.

14.7 × 10 × 17 = equivalent quantity = 2500 g.p.m.

2. For a loss of 0.112 ft. per 100 ft. and 2500 g.p.m. flowing, a 21 in. main is required, a 21 in. falling ¼ of the distance between a 20 in. and 24 in., above the 20 in. on the pipe diagram. Therefore, we will arbitrarily carry the 24 in. main from a point 8.5 ft. from the first pair of laterals to and including the third pair of laterals, which is ¼ of the total length of the main.

3. The loss in 25.5 ft. of 24 in. flowing 2500 g.p.m. is 0.015 ft. and the loss allotted for the remainder of the main is 0.1145 — 0.015 = 0.0995 ft.

$$\frac{0.0995 \times 100}{(102 - 25.5)} = 0.130 \text{ ft. per 100 ft.}$$

4. For the second section $N_2 = N_1 - 6 = 18$ and from Table I $X_2 = 11.3$.

11.3 × 10 × 17 = equivalent quantity = 1920 g.p.m.

5. For a loss of 0.13 ft. per 100 ft. and 1920 g.p.m. flowing an 18.3 in. pipe is required, 18.3 in. falling 0.3 of the distance between 18 in. and 20 in. above the 18 in. on the pipe diagram. Therefore, we arbitrarily will carry the 20 in. a distance equal to 0.3 of the remaining distance of 76.5 ft. = 22.9 ft. or to a point 5.9 ft. beyond the 5th pair of laterals.

6. The loss in 22.9 ft. of 20 in. carrying 1920 g.p.m. = 0.021 ft. We now have 0.0995 — 0.021 = 0.0785 ft. =

$$\frac{0.0785 \times 100}{102 - 25.5 - 22.9} = 0.146 \text{ ft.}$$

per 100 ft. as the allowable loss in the remainder of the main.

7. For the third section $N_3 = N_1 - 6 - 4 = 14$ and from Table I for $N_3 = 14$, $X_3 = 8.85$.

8.85 × 10 × 17 = equivalent quantity = 1500 g.p.m.

8. For an allowable loss of 0.146 ft. per 100 ft. and 1500 g.p.m. a 16.2 in. is required, 16.2 in. falling 0.2 of the distance between a 16 in. and 18 in. above the 16 in. on the pipe diagram. We arbitrarily will carry the 18 in. a distance equal to 0.2 of the remaining distance of 53.6 ft. = 10.7 ft. or to a point 8.1 ft. beyond the 6th pair of laterals.

9. The loss in 10.7 ft. of 18 in. flowing 1500 g.p.m. = 0.010 ft. We now have 0.0785 — 0.01 = 0.0685 ft. =

$$\frac{0.0685 \times 100}{102 - 25.5 - 22.9 - 10.7} = 0.159$$

ft. per 100 ft. as the allowable loss in the remainder of the main.

10. For the 4th section $N_4 = N_1 - 6 - 4 - 2 = 12$ and from Table I for $N_4 = 12$, $X_4 = 7.79$.

7.79 × 10 × 17 = equivalent quantity = 1360 g.p.m.

11. For an allowable loss of 0.159 ft. per 100 ft. and 1360 g.p.m. a 15.95 in. is required. Therefore, since a 16 in. is so close to the actual required size we will make the remainder of the main a 16 in.

12. Our layout for the main now comprises a 24 in. extending to a point beyond the third pair of laterals, a 20 in. extending to a point beyond the 5th pair of laterals, an 18 in. extending to a point beyond the 6th pair of laterals, and a 16 in. extending to a point beyond the last pair of laterals.

A compound main with one way laterals or a compound lateral can be designed by the same process with the exception that Table II should be used. After the various sizes are determined the losses should be checked to be certain that the total distribution system losses conform to the losses allotted to it.

In Example No. II the calculations have been carried out on the basis of showing that the losses in a compound main can actually be made to equal the predetermined losses for the main rather than on a practical basis. In the same way, the actual losses in a compound lateral can easily be made equal to the predetermined losses allotted to it. To adhere rigidly to the principle of making the actual losses in a compound main or lateral equal to the predetermined allotted losses will not always give practical results, and in order to secure a practical design it will be necessary for the designer to permit some variation in the percentage of the total loss to be allotted to the main or laterals. We consider the result obtained in Example I as practical and economical for the data used.

Acknowledgment.—The foregoing is taken from the April Illinois Engineer, the official publication of the Illinois Society of Engineers.

Cost of Water at Charleston, South Carolina

Some interesting statistics on the cost and income for water delivered to the distribution system of Charleston, S. C., are given in the 1928 report of J. E. Gibson, manager and engineer of the water department. The following table shows the average cost for the period 1921 to 1928 inclusive:

	Per 1,000,000 gal.
Pumping and Distribution:	
Operation and maintenance of mains	$ 8.99
Operating plant, including fuel and purifiers	33.58
Maintenance of machinery, buildings and filters	5.61
General officers, clerical assistants, insurance, legal and office expenses	20.35
Total, general, pumping and distribution	$ 68.53
Fixed Charges:	
Sinking fund and depreciation	19.63
Interest, bonds, loans and taxes	37.48
Interest on surplus invested in plant	19.67
Total fixed charges	$ 76.78
Extraordinary Expense:	
Drought, repairing, repairs, relocation of mains	8.84
Grand total, all expenses	154.15
Gross income from sale of water	167.81

Heavy Oil Tanks Moved on Greased Skids

A Universal crane and a track of well-greased plates were the means of moving two 10,000-gal. oil tanks, weighing 12,000 lb. each, a distance of about 250 ft. recently. The tanks were 28 ft. high and surrounding conditions necessitated moving them in a vertical position. The crane backed up to a tank, the hook block was fastened to the top of the tank and the bottom of the tank was lashed to the rear of the truck frame. When the tank was unfastened at its base, it was supported from the crane boom and skidded along a track of greased plates to its new position. The job cost the oil company $150.

Chlorinated Copperas and Ferric Chloride as Coagulants

A Recent Development in Water Purification Processes

By L. H. ENSLOW
Research Engineer, The Chlorine Institute, Inc., New York City

THE topic on which I am to speak—coagulation—is not new, but I believe the coagulant,—chlorinated copperas,—is new to most of those present. Neither of the components is new, but the combination of them to produce a coagulant is of rather recent development and its practical application in water purification is little more than a year old.

Coagulants.—The oldest known coagulants to be employed by man for clotting suspended particles in turbid water are the alums. The Chinese apparently practiced water clarification with alum before the Christian era. Artificial coagulation with aluminum salts has been materially improved within recent years as a result of a more scientific application and control of influencing factors such as the hydrogen ion concentration, better mixing arrangements and prechlorination of the raw water.

Long before the Chinese applied aluminum compounds artificially as coagulants Mother Nature had supplied the universe with a natural coagulant which contained the elemental substance on which all life is dependent, i. e., iron.

Water Coagulation Unassisted by Man.—In the natural decoloration and clarification of impounded waters it is known that iron and not aluminum is the responsible element. The soil and vegetation thereon contain iron in organic combination. The iron is liberated as ferrous iron as a result of subsequent anaerobic decomposition. In the ferrous state the iron will not precipitate until the surface contact with oxygen containing atmosphere produces ferric iron. In the ferric state the iron will combine with fresh organic coloring matter to produce flocculation and precipitation of the colloidal coloring matters. The reaction is apparently not one dependent upon ferric hydroxide formation and subsequent absorption of coloring matter, but rather consists of the production of a complex compound in which the negatively charged coloring matter is combined with the positively charged ferric iron to produce a bulky floc which settles. On reaching an oxygen deficient zone at or near the bottom of the water body, decomposition again releases some of the iron in the soluble ferrous form. Temperature changes or wind action produces an overturn of the stratified water and the iron again is reoxidized and further precipitation ensues. This cycle repeats to produce color removal and clarification.

Raw Water Prechlorination as an Aid to Coagulation.—Robert Spurr Weston[1] several years observed that color removal by coagulation with alum could be materially improved if the raw water was first chlorinated. His experience also showed that the alum required was thereby reduced. A number of experiences of similar nature have been reported since. Watkins at Norfolk, Va., has effectively employed prechlorination since 1923 and the plant of the Newport News Water Co. was also among the earliest to adopt prechlorination. Prechlorination at Norfolk has made it possible to reduce the alum requirement and thus effect an appreciable economy.

Several explanations to account for the improved coagulation effected by chlorination of raw waters have been advanced. In the writer's opinion, the presence of ferrous compounds in the raw water constitutes at least one valid explanation. The oxidizing effect of the chlorine renders the iron immediately effective as a coagulant whereas in the ferrous state it had no effect. In other words, chlorine does quickly that which nature performs slowly. Alone, the quantity of iron present may be only sufficient to secure "pin point" flocculation, but is sufficient to reinforce the artificial coagulant added and thereby a saving results. The iron oxidation theory seems to explain best the writer's early ideas that prechlorination appeared to serve as an artificial "ageing" process which rendered the coloring matter more readily coagulated. At Wausau, Wis., prechlorination of the raw water containing appreciable ferrous and sulphur compounds has indicated that an alum saving of 33 per cent can be expected.

Artificial Coagulation with Iron Compounds.—Ferrous sulphate ($FeSO_4$:$7H_2O$), known in the chemical trade as "copperas," has been employed in coagulation for many years. Copperas in coagulation work has always been used with lime in order that the ferrous iron will take up oxygen and pass to the ferric state. Because of the high alkalinity necessary (pH 9.0 or higher)[2] ferrous salts have, as a rule, not proved to be satisfactory coagulants for the soft colored waters, or for the soft turbid waters. Both of these types of waters usually coagulate efficiently only in the acid range, i. e., below pH 7.0, and the addition of alkaline material, if practiced, must be carefully controlled.

Ferric Chloride.—Ferric chloride ($FeCl_3$:$6H_2O$) is one of the oldest coagulants known. Its use was in vogue in the early days of chemical precipitation of sewages and is very apt to return to favor. It was employed as a water coagulant to a limited extent also and interestingly enough was used in Holland, under the guidance of Dr. Duyk in 1902, in combination with hypochlorites, thus simultaneously securing prechlorination. The process was termed the "Ferro-chlor Process," and has been favorably reported upon in America by Prof. Geo. C. Whipple.[3] Apparently the lower cost of aluminum sulphate has made the use of ferric salts unattractive. Recently, however, ferric salts have become available at attractive prices and probably their use will return to favor.

The investigations of coagulants by Miller[4] of the United States Public Health Service included ferric chloride and ferric alum in laboratory studies of water coagulation in which it has been shown that ferrous sulphate coagulated only at high alkalinities (pH 9.0 and above) but that ferric chloride coagulated satisfactorily at low alkalinities (pH 5:0) and also at various higher values. Mohlman and Palmer[5] of the Sanitary District of Chicago, in 1925 conducted important investigations in the coagulation of sludge from the activated sludge sewage process. In these studies ferric chloride was shown to be superior to all other coagulants, and functioned at very low alkalinities.

Chlorinated Copperas.—In searching for the cheapest available source of ferric iron it was but logical to consider the oxidation of copper as ($FeSO_4$:$7H_2O$) with liquid chlorine. This was successfully done, and this new coagulant—chlorinated copperas—while slightly less efficient than ferric chloride, proved to be vastly superior to alum in sludge dewatering. The method employed is given in the paper[6] cited. It served admirably at Chicago, was promptly investigated by Houston, Tex., and Milwaukee, Wis., and, with slight modification, was adopted.

The simplicity and the economy with which ferric iron is secured from the

cheapest available iron salt—copperas—and the cheapest and most powerful known oxidizing element known—chlorine—are appealing. The reaction involved is theoretically the following:

$$6FeSO_4 + 3Cl_2 = 2Fe_2(SO_4)_3 + 2FeCl_3$$

in which one pound of chlorine is required for 7.8 pounds of copperas.

$$Cl:FeSO_4 . 7H_2O = 35.46:278 = 1:7.8$$

In practice the ratio has proven to be 1 chlorine to 8 copperas.

The First Practical Use of Chlorinated Copperas in Water Purification.—For about one year chlorinated copperas has been in use at Elizabeth City, N. C., for coagulating the difficult and highly colored water from the Great Dismal Swamp area. To succeed with any process so radically new and different required ingenuity, perfection of practical arrangements, and tenacity on the part of L. L. Hedgepath,[67] then superintendent of the Elizabeth City plant. It was the good fortune of the writer to have interested him in experimenting with chlorinated copperas.

Producing Chlorinated Copperas Solution.—The arrangement for producing chlorinated copperas is very simple. It consists of a dry feed machine which delivers copperas to a small baffled solution vat beneath, and a chlorinator. The copperas in solution is conducted by gravity or, where necessary, by an ejector, through a corrosion resistant pipe line to the point of application to the raw water. Just beyond the copperas solution vat chlorine water conducted from the chlorinator is introduced into the pipe line through a rubber hose. Thus the chlorination of the copperas is effected during its passage to the point of application. Knowing the rate of delivery of the copperas required for the coagulant dosage, the chlorinator is set to deliver one eighth as much chlorine. It is better practice to add, as a margin of safety, about 10 per cent more than the theoretical calculated chlorine in order to preclude any possibility of passing ferrous iron into the water. The slight excess chlorine possesses a distinct value in improving plant performance because it serves in the capacity of prechlorination and is, therefore, not to be considerated wasted.

To date no other plants producing potable water have adopted chlorinated copperas on a practical scale. However, at a paper mill in Chicago where the foul Chicago River water is coagulated and filtered, chlorine and ferrous sulphate are producing results superior to the previously employed lime-iron coagulation. At this writing a demonstration is under way at a plant in Alabama.

A number of laboratory scale experiments have been carried on at several plants and almost without exception chlorinated copperas or ferric chloride has produced results which warrant large scale tests. Mr. Watkins of the Norfolk plants and Mr. Baldwin of the Richmond plant have carried out some small scale tests with chlorinated copperas.

General Remarks Concerning Ferric Iron Coagulation.—The range of alkalinity of the treated water in which ferric salts coagulate efficiently is very broad as compared to the ferrous salts or aluminum salts.

Where the removal of larger quantities of coloring matter is the problem the coagulation is most effective with little if any addition of artificial alkalinity. In some instances in connection with industrial waste—notably laundry wastes—addition of acid is beneficial. The optimum for very highly colored swamp waters is within the zone pH 3.8 to 4.7. This range is covered by Brom Cresol Green, and with Methyl Orange will indicate slight acidity to slight alkalinity.

Tannin is precipitated from tanliquors when acidified to a pH value under 4.6 and addition of alkali increases the solubility of tannin. The maximum dispersion occurs at pH 8.2 to 9.2 (i. e., in the normal carbonate range of alkalinity). This explains in part the failure of ferrous salts and lime in organic color removal and the inefficiency of aluminum salts at a pH value above 5.5. It may also explain the difficulty of removing color with alum without, at the same time, producing a filter effluent containing residual alum. At Elizabeth City, for example, the most effective color removal with alum is secured at a pH value not exceeding 4.9. In other instances the optimum is as low as pH 4.0. Under such conditions, aluminum compounds pass the filters.

Where the color removal is not so difficult and the amount is not large, ferric coagulation is effective over a wide range of pH value and in some instances it is possible to secure coagulation, color removal and carbon dioxide elimination with ferric iron and lime or soda at one operation, i. e., at pH values up to 8.2. On the whole, however, it is safer to recommend that color removal be practiced with the minimum required alkalinization or without any, and that pH adjustment to prevent corrosion be practiced after filtration, or just ahead of the filters if the latter practice proves to be more advantageous in securing longer filter runs.

When coagulating soft turbid waters carrying no appreciable soluble color the ferric coagulation is usually efficient at almost any pH value up to and including the point at which the corrosive quality has been corrected by alkali addition.

It seems apparent that in color removal the acidity (low pH value) plays an important role in inhibiting the formation of soluble or peptized iron compounds and encouraging the formation of bulky complex organic and basic ferric precipitates. These iron precipitates have adsorption properties far superior to the true ferric hydroxide floc. The higher the alkalinity, the greater is the tendency to produce hydroxide floc and consequently lowered efficiency in colloidal waters.

Because of the greater atomic weight of iron, the ferric complexes are higher in gravity than the similar aluminum complexes. The floc upon formation is very bulky but subsequently, at the bottom of the basins, shrinks markedly. The iron present is capable of combining with certain gases produced during putrefaction of organic sludges.

As to economy of coagulant—less ferric iron has been required than has been true of alum for the same result in connection with color removal. For turbidity removal the ferric salt required is less, although not as noticeably so as when dealing with color removal. The comparison is made on a pound for pound basis, employing commercial copperas ($FeSO_4:7H_2O$) which after chlorination has a 28.5 per cent Fe_2O_3 content as against ordinary filter alum containing 17 per cent Al_2O_3.

Cost Data.—Very little can be said at this early stage concerning cost of coagulation with chlorinated copperas or ferric chloride as compared with other coagulants.

At Elizabeth City the most recently available figure is $12.00 per m.g. when applying 3.25 grains per gallon of chlorinated copperas as the primary coagulant, and 0.75 grain per gallon of sodium aluminate as the secondary coagulant; this against a somewhat higher cost for alum and sodium aluminate. In addition, however, the better results from the ferric coagulant should be taken into account.

Recently figures have been secured to show the delivered cost of chlorine and copperas for producing chlorinated copperas at New York which yield the following data:

Material	Per cwt. Delivered
Sugar copperas in bags (car lots)	$0.65
Chlorine in one ton containers (15 tons per carload)	3.33

8 copperas + 1 chlorine, to produce chlorinated copperas, gives a chemical cost of $21.38 per ton of copperas chlorinated, i. e., roughly $1.07 per hundred. Employing copperas delivered in bulk cars the cost of chlorine plus copperas becomes $18.88 per ton, or $0.95 per hundred for a product having 28.7 per cent Fe_2O_3 content.

Milwaukee, Wis., is securing a 5-year supply of ferric chloride at approximately $0.95 per hundred (delivered Milwaukee) for a material containing 45 per cent $FeCl_3$, i. e., 21.6 per cent Fe_2O_3 equivalent. Approximately the same cost as that at Milwaukee will apply for ferric chloride at New York. The material is shipped as a solution in rubber lined tank cars, but the consumer pays only for the actual $FeCl_3$

content delivered, the manufacturer standing all freight charges, including that on the 55 per cent water content.

Chlorinated copperas may be produced either at Richmond or Norfolk, Va., at a chemical cost including all freight charges of:

Materials (including all freight charges)

	Cost per cwt.
Sugar copperas in 200 lb. bags (car lots)*	$0.775
Chlorine in 150 lb. cylinders (car lots)	5.75
Chlorine in one ton containers (15 containers per carload)	3.46

Employing the ratio of 1 chlorine to each 8 of copperas, the following costs per 100 lb. of copperas chlorinated result:

A: From chlorine purchased in 150 lb. cylinders:

100 lb. copperas	$0.775
12.5 lb. chlorine	0.719
	$1.494

B: From chlorine purchased in 2000 lb. containers:

100 lb. copperas	$0.775
12.5 chlorine	0.432
	$1.207

We believe that the economics involved and the proven efficacy of ferric salts as coagulants justify the consideration of the persons interested in water purification, sewage disposal and industrial wastes treatment.

* With copperas shipped in bulk, i. e., loose in the car, a reduction of $2.50 per ton for copperas is in order.

Channel Crossing Utilizes Flexible-Joint Pipe

In connection with the construction of the new West Side sewage treatment works of the Sanitary District of Chicago, it was necessary to carry a 12-in. water line across the main channel of the sanitary canal of the District. The illustration presented herewith depicts the method of making this crossing by assembling 12-ft. lengths of flexible-joint cast-iron pipe on a barge anchored across the channel and lowering the assembled line to the bottom of the canal.

Before installing the line in this manner the contractor made a test of the joints on shore. Several lengths of the pipe were joined and subjected to a pressure of 150 lb. per sq. in. with the test section in a straight line. This pressure was held while the joints were deflected 15 degrees and again brought to a straight line. No leakage being apparent, installation of the flexible-joint line was begun.

The submerged section of the crossing required 37 of the 12-ft. lengths. The joints were made up on the barge and on the shore. One end of the line was fastened at the shore-line and the other end was allowed to rest free on rollers so that the flexible string would slide down the bank and take its place at the bottom of the channel when lowered. As shown, each length of pipe was supported from the barge by a block and tackle. The lowering was carefully supervised, in order that no joint might be deflected an undue amount. Upon completion of the lowering, the free end of the flexible line was connected to the bell-and-spigot line on the shore. The completed line showed no leakage under a pressure of 150 lb. per sq. in.

By installing flexible-joint pipe in this manner, the services of a diver were not required except for inspection of the line.

FitzSimons & Connell Dredge & Dock Co. were sub-contractors for this work.

Iron Oxide for Gray Concrete

Colored concrete highways may serve as an intriguing variant of the present common white surfaces in the future. In discussing the sheet concrete pavements of Erie County, N. Y., George C. Diehl, county engineer, notes the instance of a high-grade residential development, the owners of which wished to get away from the white color of ordinary concrete. The pavement was given a slate-gray hue by including in the top-course mix 1 lb. of iron oxide per bag of cement.

Installation of 12-In. Line for the Sanitary District of Chicago. Joints Made Up and Line Suspended, Ready for Lowering

The Use of Rock Asphalt in Middletown, Conn.

Resurfacing Concrete and Macadam Pavements

By G. ALLEN SCHAEFER
Director of Public Works, Middletown, Conn.

MIDDLETOWN has done some very interesting work with rock asphalt within the last few years. The writer, therefore, felt that a brief outline of some of its operations would prove of interest.

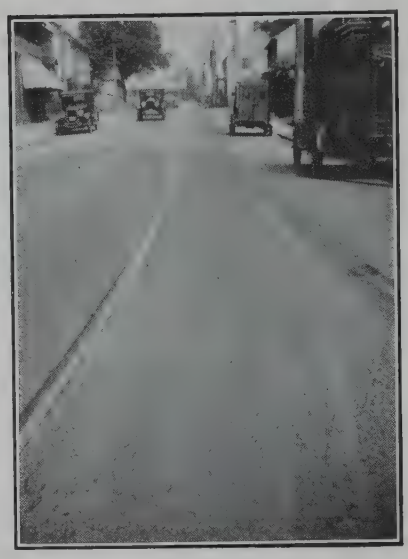
When the writer was appointed director of public works he became very much impressed with the material which his predecessor used in a limited quantity for patch work.

Resurfacing Worn Concrete Pavements.—After a very thorough investigation it was decided to use Kentucky rock asphalt for the resurfacing of Mount Vernon St. The existing pavement in the street was of cement concrete. This was very badly worn, especially along the trolley rails. In fact in many places the pavement heaved and was higher than the rails, concrete was chipped wherever such a condition existed and the entire area was then resurfaced from curb to curb featuring the Kentucky rock asphalt (Kyrock) to an edge where chipping was unnecessary.

Resurfacing Old Bituminous Macadam.—The residents along Mount Vernon St. and the officials of our city were so well pleased with the results that it was decided to continue our work with Kentucky rock asphalt during the year 1927. Washington St. was the first operation. The old bituminous macadam wearing surface was scarified wherever necessary. Two inch broken stone was added in sections where close examination proved the base to contain insufficient stone. The roadway was then reshaped and thoroughly rolled with a ten ton roller. The Kentucky rock asphalt (Kyrock) wearing course was applied in a layer 2¼ in. loose which compacted to 1½ in. Scarifying was done on that portion of Washington St. between Main and High St. The pavement between Vine and Thomas St. was not scarified. The surface was thoroughly broomed and then covered with an asphaltic paint having a penetration between 30 and 60. As soon as the paint became tackey the rock asphalt was applied as in previous operations.

Court St. from Broad St. to Valley RR. was resurfaced in a similar manner.

Disintegrated sections of the existing cement concrete pavements on Summer St. and South Main St. were resurfaced with rock asphalt the concrete surface being painted before applying the new wearing course material.



Resurfaced Concrete on Mount Vernon St., Laid in 1926. Picture Taken April, 1929

Part of Hartford Ave. which runs under the railroad bridge was also resurfaced. During the overflowing of the Connecticut River in October, 1927, approximately 3 ft. of water covered the rock asphalt surface for about two days. Although miles of pavement were ruined by the overflowing of this river the present condition of the underpass is as good as the day it was laid.

Rock Asphalt Wearing Course.—The work performed with Kentucky rock asphalt during 1927 was further proof to us that this material suited our needs, and it was therefore decided to continue the work with it. The first street to be built in 1928 was North Main St. a 6 in. compacted water bound macadam base built of 2 in. trap rock upon which was spread the Kentucky rock asphalt wearing course.

The following streets were also built in 1928 in similar manner: Johnson St. from North Main St. to Berlin Branch RR. College St. from Main St. to Broad St. Church St. from Broad St. to Hotchkiss St. Washington St. from High St. to Park Place. Berlin St. entire length.

Costs.—Approximately 2,760 sq. yd. were resurfaced by L. Suzio & Co. of Meriden, Conn., during 1927 at $1.80 per sq. yd.

In 1927 A. Brazos & Sons, Middletown, was awarded the contract. Approximately 20,000 sq. yd. were resurfaced at the following unit prices:

Scarifying 15 ct. per square yard.

Broken stone rolled in place $3.50 per ton.

Kentucky rock asphalt (Kyrock) wearing surface $1.62 per square yard.

A. Brazos & Sons were again the successful bidders in 1928. The unit prices on approximately 30,000 sq. yd. were:

Excavation $1.15 per square yard.

Broken stone rolled in place $3.50 per ton.

Kentucky rock asphalt (Kyrock) wearing surface $1.50 per square yard.

The average cost of completed pave-

Spreading Rock Asphalt on 6 in. Macadam Base in 1928 on Church St.

View of Church St., in April, 1929

ment on work performed during 1928 was $3.00 per square yard.

The writer's close observations of the completed rock asphalt pavements proved to him that such a wearing course improves with age. There appears to be absolutely no rolling, shoving or creeping of the material. The Silica sandstone aggregate gives it the non-skid quality which in the writer's opinion is worthy of very serious consideration especially when deciding upon pavement for a street having an appreciable grade. All cracks appearing on the surface due to the opening of the base knit under traffic within a comparatively short time.

All operations were under the personal supervision of the writer as well as the engineers of the Kentucky Rock Asphalt Co. The wearing course was laid in each instance in accordance with the specifications of the Kentucky Rock Asphalt Co.

Coagulation of Highly Colored Waters

Prechlorination and Filtration at Norfolk, Va.

By WILLIAM W. WATKINS
Chief Chemist, Bureau of Water, Norfolk, Va.

ABOUT a year after taking charge of the Norfolk, Virginia, filter plant in 1922 the possibilities of using liquid chlorine to reduce the amount of alum necessary to coagulate the highly colored waters were taken up and it has proven that a material saving in dollars and cents as well as a better quality of water could be produced by the addition of liquid chlorine to the raw water.

In any discussion of Norfolk's water supply it is necessary to always keep in mind the fact that there are two supplies and that while they have the same general method of purification the differences will only be touched on in this paper.

Norfolk's Water Supply. — The Moores Bridges plant is located on the edge of Princess Anne County about six miles from the heart of the city. The water is impounded in a series of lakes connected by canals. These lakes were old salt water inlets dammed off from Chesapeake Bay and allowed to freshen up. This supply has been in use for about 50 years and at the present time furnishes about 60 per cent of the daily consumption. The filter plant was built in 1898 and revamped in 1921.

While this water will run an average color of 50 to 60 on the platinum cobalt scale it occasionally reaches the color of 160 for a few days at the time. The turbidity will average about 25 but owing to the topography and cultivation of the surrounding country it sometimes runs to 5000. The free carbon dioxide is very susceptible to seasonable changes but the alkalinity to methyl orange (30 p.p.pm.) is fairly constant throughout the year except after very heavy rainfall when it becomes necessary to add soda ash to replace the natural alkalinity of the raw water lost by dilution.

The Lake Prince Filter Plant is located on 37th Street near the Lambert Point coal piers. Lake Prince, itself, holding about 3.7 million gallons of water, is located in Nansemond County about 6 miles southwest of Suffolk. Water from Lake Prince is pumped to the filter plant through 20 miles of woodstave, concrete and cast iron pipe with crossings under the Nansemond and Elizabeth Rivers.

This water carries a higher color than Moores Bridges, averaging around 70. In the three years of its operation the turbidity has never reached as high as 50 but the color has been as high as 200 for periods of ten days. With an average alkalinity of 40 p.p.m. and a pH of 7.0 no artificial alkalinity is necessary for coagulation.

The combined capacities of the two plants is 28,000,000 gal. daily, the average consumption being about 12,500,000 gal. per day either plant is capable of carrying the load, but owing to the balancing of the pressure it is found to be more economical to run on a 7 to 5 basis, that is 7 million at Moores Bridges and 5 at Lake Prince.

The Former Treatment.—Prior to November, 1923, the general method of treatment at the Moores Bridges plant can be briefly summarized. Aluminum sulphate in the average of 2.00 grains per gallon was added to the raw water, which was allowed to settle for 4 hours, filtered through rapid sand filters, CO_2 reduced with hydrated lime, and chlorine added for sterilization. In addition, chloride of lime was added to the wash water and tons of copper sulphate were used annually to keep down algae. The average percentage of wash water was 4 to 5 per cent. The average filter runs were about 16 hours.

In the fall of 1923 experimental work was done on the use of liquid chlorine to assist in the coagulation of the water. The work was carried on experimentally for about a year after which time it was decided to make a permanent installation of the chlorine machine.

Application of Chlorine.—The chlorine was applied to the raw water in the mixing chamber about one minute ahead of the alum. It was found that best results could be obtained by adding approximately 6 pounds of chlor-

Resurfaced Old Macadam Constructed in 1927 on Washington St.

ine per million gallons of water. This would give a residual of 0.1 p.p.m. ten minutes after application or as the water passed from the mixing chamber into the coagulating basin. Higher residuals did not seem to lessen the quantity of alum used at all. Unless 0.1 residual was carried no results in reduction were obtained.

Before prechlorination or what should be more properly called split-chlorination, was tried, it required from 4 to 6 lb. of chlorine per million gallons of water for sterilization. With the split dosage it required 5 lb. for the prechlorination and 2 to 3 for sterilization. The Lake Prince plant was not operated long enough before split-chlorination was adopted to have any data on alum alone to work from. When prechlorination was tried out at that plant it was found that 7 lb. per million gallons of water gave the best results. This gives a residual of 0.2 p.p.m. 20 to 30 minutes after application. When the Lake Prince plant was put in operation a good deal of trouble was experienced with algae—asterionella being the type giving the taste and odor troubles. For reasons governed by local conditions it was not desirable to use copper sulphate so prechlorination was adopted as regular routine and has been found very effective in stopping algae taste and odors.

Results of Prechlorination.—Aside from the actual amount of alum saved it is found to be much easier to get the maximum color removal with split chlorination than with alum alone. The length of the filter runs were increased from 16 to 24 hours, and the filter beds are kept in much better condition by the use of split-chlorination.

A marked reduction in the bacterial loading was noted with the prechlorination dosage as applied. While Norfolk still adds chlorine for sterilization purposes it is done as an added precaution rather than as a necessity.

I know of no better way to give you my reasons for the continued use of a split dosage of chlorine than to quote from a report written several years ago to Mr. W. H. Taylor, Director of Public Works, Norfolk.

"I find that I can save from 0.4 to 0.6 grains per gallon of alum by the use of 6 lb. of chlorine per million gallons of water. The lower dosage of alum gives a lower free carbon dioxide content and for that reason I am able to save some lime. (The fact that the carbon dioxide content is so variable in the raw water makes it very hard to get the exact quantity of lime saved). However, to offset the saving in lime there is the increase in the amount of chlorine fed. Formerly I used 5 to 6 lb. per million gallons of filtered water but now I use about 9 lb. for the combination of prechlorination and sterilization.

Aside from the saving in alum the greatest advantage of prechlorination is in the saving of copper sulphate and wash water. Prior to prechlorination there were times when it was impossible to get filter runs of over 6 hours without the use of copper sulphate. Since I have been using chlorine the minimum average for a two-year period is a twelve-hour run, maximum being well over 20 hours. During this period no copper was used. As well as I can estimate the saving is about a dollar a day on the wash water end of it.

There is another item which cannot be put down in dollars and cents and that is the condition of the filter beds, which are in much better shape than formerly.

I am confident that the City of Norfolk is saving from $5.00 to $7.00 per day on alum, lime, and wash water, leaving the question of copper sulphate and filter beds out of the consideration.

Red Water Troubles.—In Norfolk, as in all other cities on the Atlantic Coastal Plain, which have soft colored waters we have our red water troubles. Perhaps I should say had our red water troubles, for we have cut down the number of complaints to those few who grumble for the sheer love of grumbling. We do not feel, however, that the problem is entirely solved and at the present time we are considering the use of caustic soda.

When hydrated lime was first used in 1922 only enough was used to reduce the free carbon dioxide to 5 p.p.m. or less. That helped but was not sufficient and at the present time enough lime is added to give a pH of around 8.6 to 9.0 with a phenol alkalinity of 6 to 8 p.p.m. What red water we do get is in dead ends and it is my firm belief that it is due to dissolved oxygen. I have not been able to establish this as a positive fact but everything points in that direction. In winter when the dissolved oxygen is greatest, 8 to 9 p. m., we have most of our trouble.

Acknowledgment.—The foregoing is a paper presented at the First Virginia Conference on Water Purification and Sewage Treatment.

Mosquito Extermination Scientific in Winnipeg

Mosquito extermination in Winnipeg, Canada, is carried out in a scientific manner under Mr. Eric Hearle, expert entomologist, who directed the research in the identification of the types and habits of the mosquitoes of the district, according to the annual report of the Public Parks Board of that city. Plans for continuous annual effort were mapped out.

According to the Toledo City Journal active extermination work by oil spraying was carried on within a radius of two miles of the city's center and for a like radius of the suburban parks and municipal golf courses. Large areas of shallow, stagnant water, forming ideal breeding pools, which were caused by the heavy rainfall, were sprayed, and excellent results obtained.

Ice Diaphragm Aids in Placing Concrete Under Water

An ingenious scheme used for cutting off salt water encountered in the drilling of a deep well at the new Proviso yard of the Chicago & North Western Ry. was described by G. A. Saint, assistant engineer with the North Western, in a paper presented before the Western Society of Engineers.

It was important that an adequate supply of soft water be provided for locomotives; hence as large a well as possible was sunk. A shaft 20 in. in diameter was sunk to a depth of 2,100 ft., at which level a pumping test was made. This test was judged unsatisfactory, as a flow of 250 gal. per minute was all that was obtained. It was decided to go deeper, and the well was sunk to a depth of 2,250 ft. A 1,600-ft. length was cased off to get rid of the hard water at the top. A second pumping test, made at the 2,250-ft. level yielded satisfactory results as to capacity, showing a flow of 400 gal. per minute. However, an analysis of the water showed the presence of 28 grains of salt per gallon, indicating that the water would be unfit for boiler use, and that some means of eliminating the salt would have to be found.

Since water from the 2,100-ft. level contained no salt, it was decided to fill the bottom 150 ft. of the well with concrete. This raised the problem of lowering the concrete through about 2,100 ft. of water without separating out the cement and finer aggregates. Following the suggestion of an old-time well driller, the concrete was lowered in a section of steel casing, 12 in. in diameter and about 12 ft. long. Two pins were placed across the bottom of the casing and a piece of ice about a foot thick was trimmed to rest on the pins and stop up the bottom tightly. The ice was placed in the casing, the remainder of the shell was filled with the concrete mix, and the whole was lowered to within a few feet of the bottom. The temperature of the water was about 60 deg. and the time of lowering was approximately 3 minutes. When the ice melted, the concrete ran out the bottom of the casing and filled up the hole.

Proviso yard covers an area of 1,500 acres just west of the city of Chicago, has a total track mileage of 230 miles and involves an authorization to date of $10,000,000. Completion of the project as contemplated will call for the expenditure of at least $5,000,000 more.

Protecting Exposed Pipe Lines

Pipe lines which must be carried over bridges may be protected from freezing temperatures by placing the pipe in a wooden box and filling the space about the pipe with an insulator such as sawdust or mineral wool.

Garbage Incineration at Toronto, Ont.

Operation and Costs of Disposal in 1928

DURING 1928 the destructor plants of Toronto, Ont., handled over 159,000 tons of household garbage and combustible material at a cost of $1.26 per ton. Some interesting facts on the operation of these incinerating plants is given in the 1928 report of George W. Dies, Street Commissioner of Toronto.

The Don Destructor.—The Don destructor was completed in July, 1917, at a total cost of $225,000, exclusive of land. The plant is of fire-proof construction throughout, and consists of three high-temperature four-cell furnace units, with combustion chambers, connecting flues, regenerators, and all appurtenances. The radial brick chimney is 25 ft. from the outside of the building, and is constructed with a self-supporting refractory lining, extending from the foundation to the top of the chimney, the inside of which is 90 in.

The overall height of the chimney, including the octagonal base and radial column, is 175 ft.

During 1928, 53,961 tons of refuse were disposed of at a total cost of $1.46 per ton, or 2.4 man hours of labor per ton. This total unit cost is based upon the total operating cost of the plant for the year, which includes tipping-floor man, charging men, stokers, ash-run men, removal of ash residue, supervision, weight scale clerk, privileges accorded employees, consisting of a half-day off per week with pay, all statutory holidays, two weeks' holidays, one month's sick pay, supplies and repairs to plant and building.

The plant has a guaranteed capacity of 180 tons per 24-hour day, but it destroys on an average of 200 tons per 16-hour day. The reduction by weight of the refuse delivered to the plant is 89 per cent.

The material delivered passes over a weigh-scale platform, where the weight is recorded. It is then drawn into the plant on to the tipping floor, where the vehicles are backed, and the contents dumped to the charging floor below. From that point it is charged into the containers of the furnaces by the charging men. The dumping of the containers is controlled from the stoking floor level, compressed air rams being provided for operating the furnace covers and the container doors. The refuse passes through the opening and drops upon a drying hearth inside and at the back of the furnace; it is then drawn over and spread on the grates, where incineration takes place. After the residue has accumulated to such an extent so as not to retard effective burning, large counter-balanced doors at the front of the furnace are raised, and the residue is removed from the grates, dropping by gravity through openings on the stoking floor, falling into steel side-dump cars (located in what is known as the ash run) of about one and a half cubic yards capacity. The trucks are moved over a narrow gauge track and placed upon an electrically-operated freight elevator, which raises the residue to the ash bin on the tipping floor level. On this floor a weight scale is provided, which records the weight of the residue before dumping it into an elevated ash bin. The removal of the residue is effected by means of adjustable chutes, through which it flows into any desired vehicle, at grade level. It will be noted that the system is gravity throughout, with the one exception, where the residue is raised from the ash run to the bin on the tipping floor level.

The furnaces are what is known as the continuous grate regenerative type, the cells are divided by low-set air-cooled surrounding castings which renders it possible to fire and clean the grates in an individual manner. The gases pass over the cells into the combustion and settling chamber; at the back end of this chamber a firebrick dividing arch is constructed, that splits the gases, a requisite portion of which pass into the air heater or regenerating chamber, the air heater being designed for pre-heating the forced draught. Any gases not otherwise utilized pass into the by-pass flue, through the connecting flues which are coupled to the main flue, and from thence into the chimney.

Wellington Destructor.—The Wellington destructor was placed in operation in April, 1925. The total cost of the plant amounted to $550,000, exclusive of land. The entrance to the plant is by an approach 250 ft. long and 24 ft. wide, with a 4 per cent upgrade. A 25-ton weigh scale is located on the causeway immediately in front of the entrance to the tipping floor.

The main building is 180 ft. long, and 100 ft. wide, with roof trusses spanning the entire width, and covered with a reinforced concrete roof upon which felt and gravel roofing is laid. The roof is designed with a monitor extending almost the full length of the building. The monitor is equipped with ventilating louvres. The building throughout is of fireproof construction. There are four floors at different levels. The vehicles entering the plant from the approach on the tipping floor level. The tipping floors extend nearly the full length of the building and are 35 ft. wide, connected by a bridge across the charging floor 20 ft. wide, thereby making it possible in an emergency to dump on each side of the charging floor, which is 10 ft. below the tipping floors.

This charging floor extends the full length of the building, and it is 15 ft. wide each side of the charging containers, which are located on the longitudinal center line of the building. The stoking floor as well as the main floor is 18 ft. below the charging floor level. These floors also represent the low grade level. Another floor, known as the ash-run floor, is 8 ft. below grade.

The capacity of the charging floor is such that it is possible to store sufficient material in an 8 hour delivery to operate the plant 24 hours.

The equipment of the plant consists of four 4-cell furnaces complete, with combustion chambers, air heaters, connecting flues, main flues and two radial brick chimneys, and all appurtenances, including forced draught equipment, air compressors and temperature recording instruments.

The general arrangements of the flues are such that it is possible to operate any desired battery of three furnaces together with any one chimney (each chimney being capable of operating three furnaces in battery), so that at all times the plant may be operated at not less than 75 per cent capacity.

Dual air compressors are provided so as to be capable of furnishing a constant supply of air for operating the container doors and furnace covers.

The Wellington destructor has a guaranteed capacity of 400 tons per 24 hours, but has during the summer months destroyed 350-400 tons per 16 hour day.

The opening of this plant in 1925, replaced the old Western Crematory on

Summary of Operation of Don Destructor, 1917-1928

Year	Total Labor Cost	Labor Cost and Maintenance	Tonnage Destroyed	Labor Cost per ton	Total Cost per ton
1917	$12,783	$16,053	12,699	$1.00	$1.26
1918	29,874	39,369	27,303	1.09	1.44
1919	27,397	41,060	27,811	1.02	1.47
1920	38,407	53,271	33,688	1.14	1.58
1921	54,237	66,760	47,392	1.14	1.40
1922	55,529	74,640	49,842	1.11	1.40
1923	54,292	69,098	44,673	1.21	1.54
1924	58,889	74,458	50,985	1.15	1.46
1925	63,147	75,648	50,159	1.25	1.50
1926	68,557	79,500	52,081	1.31	1.52
1927	66,462	74,539	51,089	1.30	1.46
1928	70,450	78,701	53,961	1.31	1.46

Summary of Operation of Crematory and Wellington Destructor, 1917-1928

Year	Total Labor Cost	Labor Cost and Maintenance	Tonnage Destroyed	Labor Cost per ton	Total Cost per ton
Crematory—					
1917	$14,487	$15,382	19,381	$0.75	$0.79
1918	16,387	19,926	18,615	.88	1.07
1919	20,889	25,725	20,751	1.00	1.23
1920	26,602	35,062	18,815	1.41	1.86
1921	29,589	35,184	21,680	1.36	1.62
1922	29,183	33,452	19,467	1.49	1.71
1923	33,016	35,769	26,638	1.23	1.34
1924	32,328	35,526	24,127	1.33	1.47
Wellington Destructor—					
1925	$64,966	$70,448	63,351	$1.02	$1.10
1926	72,475	79,467	69,822	1.03	1.13
1927	76,095	84,142	77,134	.98	1.09
1928	80,876	90,059	80,471	1.00	1.12

Strachan Avenue, a plant which had been in operation for over 30 years. It consisted of two furnaces, operating under natural draught, and disposed of 80 tons of refuse per 16 hour day. While the crematory was of rather antiquated design, and the building portion was in latter years beyond repair, it served its purpose well, and was no doubt a modern plant at the time of its construction.

The total labor cost includes all labor engaged in the disposal of the refuse, supervision, weigh scale clerk, and privileges accorded employees. The labor cost and maintenance includes the total labor cost, plus repairs to plant and building, supplies and equipment, which is the total operating cost of the plant for the year. The ash residue amounts to 11.2 per cent of the total tonnage destroyed.

Island Incinerator.—The Island Incinerator is situated at Centre Island. It was placed in operation in 1915 at a cost of $25,000, exclusive of land. The plant consists of one burning unit operating under natural draught, and destroys all garbage, rubbish and night soil collected upon the Islands. No fuel is used to augment the fires.

There is only one stoker engaged at this plant, and during 1928, 648 tons of material were destroyed, at a total cost of 2.3 man hours of labor per ton. The total operating cost of the plant during 1928 amounted to $952.80.

The collection and disposal services at the Island commence in the early part of May and terminate in October. The consistency of the material collected is considerably heavier than that removed in the City, and is principally composed of table refuse and night soil. The material is collected in metal receptacles and conveyed by horse and cart to designated points where the cans are transferred to a five-ton workboat, which conveys the refuse to the incinerator dock. The cans are placed upon a push truck operating upon narrow-gauge rails and moved into the building, then raised by elevator to the charging floor. The receptacles are emptied into the charging holes where the refuse falls upon the drying hearth, to be later distributed over the grates by the stoker.

The Island collection service is rendered by a foreman, two drivers and vehicles, two laborers, and a work-boat, the foreman being responsible for the operation of the boat. The service is under the supervision of the Superintendent of the Eastern Division, and during the season of 1928 was performed at a total cost of $4,988.30, which cost is included in the general summary of the refuse collection service.

The total labor cost includes all labor engaged in the disposal of the refuse. Labor cost and maintenance of plant and building, supplies and equipment, which is the total operating cost of the plant for the year. The ash residue amounts to approximately ten per cent.

Summary of Operation of Island Incinerator, 1921-1928

Year	Total Labor Cost	Labor Cost and Maintenance	Tonnage Destroyed	Labor Cost per ton	Total Cost per ton
1921	$576	$ 697	668	$0.87	$1.00
1922	662	755	744	.88	1.01
1923	633	1,200	671	.94	1.79
1924	729	994	716	1.02	1.31
1925	763	966	701	1.08	1.41
1926	720	1,024	656	1.15	1.56
1927	758	978	663	1.14	1.48
1928	690	952	684	1.02	1.39

Flushing in Backfilling

The problem of backfilling trenches in such a manner that the maximum amount of dirt excavated will be replaced and the fill thoroughly settled is one which confronts contractors in sewer and water-supply work. It will generally be found that flushing the trench produces better results than hand tamping if the puddling operation is performed properly and if the soil is not clayey.

To secure the most complete settlement, fill the ditch with dirt, piling the excess over the fill, and flush the trench from the bottom. A pipe may be attached to the end of the hose and pushed through the dirt until it strikes the sewer or water main. The water should be allowed to flow until it reaches the top of the trench. This operation is repeated at intervals along the pipe line, the length of intervals depending upon the nature of the soil and the size of the trench. Flushing should never be done from above, as the puddled earth is likely to lodge part way down the ditch, preventing proper settlement of the bottom of the fill. Contractors who have relied upon hand tamping may be surprised to find the judicious use of water producing a settlement of 1 or 2 in. in an ordinary hand-tamped fill.

In sewer work, there is danger from the collapse of manholes during backfilling. If the flushing method has been used, the collapse of a manhole may introduce water into the sewer, resulting in damage to the work or injury to the workmen. Care should be taken to maintain a uniform pressure on all sides of the manhole during backfilling.

Sanitary Engineering Courses

The data concerning sanitary engineering courses in colleges in the United States, prepared in 1924 by Isador W. Mendelsohn, Associate Sanitary Engineer, U. S. Public Health Service, has now been brought up to 1928. The data for the later year are given by Mr. Mendelsohn in a comprehensive article in the March 22 issue of Public Health Reports. He summarizes his findings as follows:

1. There are 16 colleges in every section of the United States at present offering either regular or optional courses in sanitary engineering.

2. There is considerable difference of opinion among the universities as to the fundamental concept of a sanitary engineering course.

3. The sanitary engineering courses are in reality civil engineering courses with certain appended subjects, such as water supply, sewage disposal, the bacteriology and chemistry of water and sewage, and a little public health.

4. Emphasis in both sanitary engineering and public-health subjects reflects in practically all the institutions the personality of the professor of sanitary engineering.

5. The number of sanitary engineering graduates annually is increasing.

6. There is a great variation in the degrees granted by the institutions for equivalent work and also in the names of the course.

7. In 4 of the 16 institutions the term of sanitary engineering course is either five or six years.

Municipal Reference Libraries.—The 15 cities of the United States that have municipal reference libraries are: Baltimore, Chicago, Cincinnati, Cleveland, Detroit, Los Angeles, Milwaukee, Minneapolis, New York, Philadelphia, Portland, Ore.; Rochester, St. Louis, Seattle and Toledo.

Recording Operating Data on Filtration

Keeping Books on the Filter Plant

By WELLINGTON DONALDSON
Of Fuller & McClintock, Consulting Engineers, New York City

IN the furnishing of drinking water to a community, the water plant operator occupies a position of very high trust in safeguarding water consumers from water-borne disease, in addition to his obvious responsibility for providing a water of acceptable physical qualities. The possible consequences from improper operation of water purification works are too serious to permit such works to be run in a loose unsystematic manner without adequate records of their performance.

Value of Plant Records.—Aside from the value of plant records in fixing responsibility they have a very definite value to the operator in allowing comparison to be made of results from day to day, month to month, etc., of his own plant and of other plants as well. By such comparison much can be done in smoothing out operation and promoting plant economies.

Adequate records of plant operation comprise the following:

(a) Primary records of quantities, water quality and such details as are useful in controlling the plant.

(b) Summaries of the essential information contained in the primary records.

(c) Reports to department head or responsible supervising authority at stated intervals.

Primary Records.—What primary records should be made? Naturally this depends a great deal on the size of the water plant, the quality of the supply, the nature of treatment and the character of operating personnel. Take for example the typical rapid sand filter for a surface supply. The minimum records that could be recommended are as follows:

(a) Amount water treated, thousand gallons.

(b) Chemicals used in treatment, lbs.

(c) Number filters in service.

(d) Number filters washed.

(e) Amount of wash water, thousand gallons.

(f) Average filter runs between washings, hours.

(g) Turbidity of raw and delivered water.

(h) Color of raw and delivered water.

(i) Residual chlorine of delivered water.

(j) Bacterial tests for B. coli and total bacteria.

Some amplification of this minimum schedule will be called for to meet local conditions. For instance, where the filtered water is pumped, the water elevation of the reservoir, the duration of pumping and power required are pertinent items. Tests for alkalinity or pH are sometimes necessary for intelligent coagulation control.

To be useful for ready comparison the chemicals used should be shown on the unit basis (pounds per million gallons, or grains per gallon), and the wash water as per cent of treated, in addition to total amounts.

The cost of operation is not included in the above list because this information although of considerable importance is seldom available to the plant operator. He can easily however show the chemical cost per million gallons, each day.

The Most Important Item.—Of the items listed above, without doubt the last or bacterial test is the most important, for assurance of the hygienic quality takes precedence over any other kind of record. In the smaller filter plant, however, the bacterial tests are made by some laboratory not connected with the water department. Very fortunately the small plant operator without any knowledge of bacteriology may have assurance of getting good bacterial results from his plants by means of the simple test for residual chlorine, which any filter operator can make.

Means for obtaining the amount of water treated is sometimes lacking, where centrifugal pumps are installed, and where the cost of a Venturi or some other type of flow meter was not felt to be justified.

Recording the Chemicals.—It is a comparatively simple matter to keep track of the chemicals used each day, but experience shows that frequent mistakes are made in recording this item. In theory each pound of chemical applied to the water should pass over the scales, so to speak. Alum, hydrated lime and soda, however, are available in containers of sufficiently standard weight to be relied upon, but where these original sacks or barrels are broken, to make up charges, scales are necessary to keep track of the actual amount of chemical fed into the water. The weight of chlorine cylinders should invariably be gotten from platform scales, devoted to that purpose alone. When solution tanks are used for alum, mistakes are frequently made in reporting the total pounds per day due to changes in the tank charges or carelessness in filling to a fixed mark. With dry feed machines, errors in reporting are common, due to depending on calibration of the dry feed machines and where no check is made by scale weight of the alum going into the hoppers.

In case of special purification plants such as iron removal, softening, and slow sand filters, the essential data to be reported must of course be adapted to the particular plant and will differ from the essential items given above for the surface water supply.

Manner of Keeping Data.—The manner in which the essential data of operation are kept depends upon the size of the plant, the operating personnel and the quality of the water supply. Where the filter plant operator is the general factotum of the water works and attends to pumping and repairing the mains, and possibly to the collection of water rents, perhaps there is nothing better than a substantial book ruled to suit the data to be recorded say on the basis of a daily entry. With larger plants printed log sheets are desirable either on a daily or weekly basis. The log sheet is particularly desirable where there is more than one operator in order to definitely fix responsibility for happenings on the shifts.

The frequency of taking and recording readings of meters, gages, chlorinators, chemical feeds, etc., should be adjusted on a common sense basis to the local conditions. In larger filtration plants it is customary to use log sheets providing for readings each hour or sometimes at two or four hour intervals. That this matter can be overdone is shown very well by the example of one city of about 50,000 people, within the speaker's observation, where the filter attendants on 8-hour shifts are kept dressed in natty monogrammed uniforms and required not only to record numerous observations each half hour, but to plot curves. They complained very properly that they were kept so busy making records that they had no time left to run the plant.

Summarizing the Records.—Next in importance to keeping good records is the summarizing of these records into condensed form where they may be easily referred to. It is a common fault of many water plants and other business enterprises as well that much valuable detailed information becomes unavailable from lack of suitable summaries systematically carried forward. As a general proposition a summary by months is the most convenient way of keeping the operating data in shape

for ready use. Printed forms are most suitable for this purpose.

It is seldom that the filter operator is given complete discretion in all matters relating to his plant. He usually has to make a report to somebody to show what is going on at his plant. The form of report is determined by the local organizations and the ideas of the executive or official in charge. Large water departments generally insist on a daily report of operations. A weekly report is preferred by many of the utility companies which operate a number of properties. A few of the state boards of health also require a weekly report of filter plant operation. The State Board of Health in this state and in a number of other states require monthly reports of operation.

A rather unusual situation came to the speaker's attention some years ago where a city of about 50,000 population had a fine new filter plant with a competent chemist in charge. He had suitable record and report forms printed to show his operation, but when his first reports went to the City Hall, he was called on the carpet and instructed by the newly appointed water commissioner to desist from sending in any reports of this kind because he didn't want them and didn't know what they meant anyhow. Happily such conditions are rare.

Recording Operating Data Not Difficult.—The recording of operating data and the making out of reports appears to be quite a task for some operators who have not been fortunate enough to secure a good education. The speaker recalls one instance where he labored with the pumping station engineer to get him to figure his chlorine dose each day. More than once the old man threw down his pencil in disgust with the exclamation that he "was hired to run the pumps and not to figger." Patience finally won, however.

The filter plant operator who happens to be lacking in good education or technical training can take comfort from the writer's assurance, based on many years of filter plant supervision, that the best records are not necessarily made out in the best handwriting nor couched in the most grammatical language. One of the most poorly operated filter plants that he recalls was in charge of a Ph.D. while one of the best cared-for filter plants was in charge of an unlettered fellow to whom a decimal point will always remain a mystery. His records were naturally crude and hard to decipher but they served their purpose admirably. He knew what was needed to be done to keep his plant in first-class condition and he did it. The main thing about him was his mental honesty and his thorough dependability, without which qualities plant records mean very little.

Acknowledgment.—The above is a paper presented at the First Virginia Conference on Water Purification held at Richmond, Va., April 25 and 26.

Inventory of Water Supply of Pomperaug Basin

For many years the Geological Survey of the United States Department of the Interior has been actively engaged in measuring the flow of the rivers and creeks of the country and in determining the quantities of surface water that percolate down to the water-bearing rocks and can be recovered through artesian wells or by pumping. At the same time the Department of Agriculture has endeavored, by elaborate investigations, to determine the amount of water that seeps into the soil, how much of it is consumed by vegetation, and what becomes of the rest. In a Geological Survey report just published (Water-Supply Paper 597-B), by O. E. Meinzer and Norah D. Stearns, an attempt is made to present, for a period of three years, a monthly and yearly inventory of the water supply of the Pomperaug Basin, a more or less typical drainage basin in Connecticut. This paper was prepared in cooperation with the Connecticut State Geological and Natural History Survey.

The problem of the circulation and storage of the water derived from the rain and snow that fall on the Pomperaug Basin is analyzed comprehensively in this report. A part of this water is intercepted by trees and other vegetation, from which it evaporates and is returned to the atmosphere without reaching the ground; a part is evaporated directly from the surface of the ground; a part flows directly into the streams and ponds and runs off, except a small amount that is lost by evaporation; a part percolates into the ground and becomes soil moisture, or penetrates to the water table, where it enters the zone of saturation and is called ground water. The soil moisture may be absorbed and transpired by plants or may be evaporated directly from the soil. The water in the zone of saturation may be transpired by plants or may evaporate where it comes near the surface, or it may seep into the ponds and streams eventually and be carried out of the basin by the Pomperaug River.

It is believed that practically no water is lost by deep percolation out of the Pomperaug drainage basin and that practically no water enters the basin from deep-seated sources. Therefore except as there is increase or decrease in surface or subsurface storage within a given period the difference between the amount of precipitation in the basin during the period and the amount of stream flow out of the basin is approximately the amount that is evaporated, directly or through the agency of plants.

Natural Storage for the Water Supply.—The water that falls as rain or snow may be stored on the surface or below the surface. Surface storage includes the water that is held in the ponds and reservoirs, and for the purposes of this investigation it includes also the water in the streams. Moreover, surface storage includes the considerable quantities of water that accumulate on the surface in winter as ice or snow. The subsurface storage consists of the soil moisture, in the zone of aeration, and of the ground water, in the zone of saturation. The storage creates an interval of variable duration between the falling of the water as rain or snow and its exit from the basin by evaporation or as run-off, and it thereby greatly complicates the problem of determining what ultimately becomes of the water that falls as rain or snow.

Estimates of Run-off, Evaporation, and Underground Percolation.—The data obtained in this investigation indicate that during the three-year period the average yearly precipitation in the form of rain or snow, stated as depth of water over the drainage basin, was 44.48 in., of which 20.66 in. was carried out of the basin by the Pomperaug River, about 23.20 in. was returned to the atmosphere by the invisible processes of evaporation from soil and surface objects and of transpiration by plants, and a small balance remained in subterranean storage. It was estimated that 11.90 in. of the yearly precipitation was carried away by the Pomperaug River without ever getting into the ground, 16.99 in. was taken back into the atmosphere by evaporation and transpiration, without having percolated down to the water table, and 15.58 in. found its way to the water table and was for an indefinite period placed in subterranean storage in the zone of saturation.

Recharge and Discharge of the Subterranean Reservoir.—At the beginning of the investigation the water table was abnormally low, and hence the subterranean reservoir was not quite filled to capacity. Consequently there was a small increase in ground-water storage during the three-year period, and the average yearly discharge from the zone of saturation was slightly less than the average yearly recharge. It was estimated that an average of 8.76 in. of ground water was discharged each year by overflow of the subterranean reservoir through springs and seeps and that an average of 6.21 in. was withdrawn from the zone of saturation by the roots of plants or through the capillary pull of the dry soil and subsequent evaporation.

Mosquito Control Operations in the Chicago District

Work of Des Plaines Valley Mosquito Abatement District in 1928

The Des Plaines district includes an area of 76½ square miles and has a population of 200,000 people. Its topography, for the most part, is flat with some hilly sections. There are two polluted streams, the Des Plaines River and Salt Creek which flow through the district. In addition there are a great many small creeks, wet weather streams, woodland pools, and cat-tail swamps.

For control work the district is divided into two sections, each section being placed under the direction of a foreman with a gang of 12 laborers and one truck driver.

During the first two months of the season these gangs engaged in the drainage and clearing of mosquito breeding areas, and later, as breeding developed, were put to work oiling the marshes. In the fall when the breeding season was over the gangs again returned to drainage work.

Section Equipment.—Each section is equipped with one ¼-ton truck, used to haul men and tools. During wet weather these trucks are rigged with barrel pumps and used to spray road ditches. During the first heavy breeding two one-ton trucks were hired to haul oil to points of distribution.

Personnel.—The district employes one sanitary engineer in charge, one assistant sanitary engineer in charge of field operations, one laboratory man in charge of the laboratory, one stenographer-bookkeeper, one river inspector, one motorcycle operator, seven house-to-house inspectors, 4 field inspectors, 2 foremen, 3 truck drivers, 1 chief inspector, 24 to 36 laborers.

The report of the district for 1928 has been issued recently and from it we have extracted the notes that follow:

Mosquito Breeding Areas.—"Consideration of permanent improvements such as will eliminate mosquito breeding areas, leads us to inquire as to what constitutes mosquito breeding areas.

"It is common knowledge that mosquitoes must have water in which to breed, but even so, not all water surfaces are inviting to mosquitoes for breeding purposes and even that portion which is chosen is given to the production of only one or several species at the time.

"The most troublesome species of the domestic group flourish in dry season when rivers and streams become polluted; woodland mosquitoes prefer the comparatively clear woodland water of woodland pools, while the predominating species of the marsh group prefer the shallow warm waters of prairie marshes and field pools. Thus it is evident that temperature and food supply of the water may control the type of breeding or change it from domestic in dry weather to marsh in wet weather, even in the same river, stream, pool or marsh. Hard rains may flush an embryonic crop of domestic mosquitoes down stream, and at the same time flood contiguous bottom lands, and hatch millions of dormant eggs of a different species.

"The percentage of the total water surface constituting potential breeding areas, varies in direct proportion to the extent of its grassy covering and the shallowness of the water. In prairies, 85 per cent of all water surfaces may be considered potential areas, whereas in the deeper and fast moving water of the rivers and streams only 40 per cent of the water surface may be considered potential breeding areas."

In the Des Plaines district the total potential breeding area in rivers, streams and prairies at the beginning of the season of 1928 was 514 acres with normal rainfall. "Approximately 75 per cent of this acreage can be eliminated by drainage and from diking and filling at an **estimated cost of** $138,233." The area remaining at the completion of such a program would be 90 acres at normal rainfall, which would be increased to 243 acres with excessive rainfall.

"Comparison of the actual acreage oiled during 1928, with that necessary to be oiled after completion of the proposed program, would indicate that mosquito production can be controlled following excessive rainfall as the acreage necessary to be oiled would be a limited amount of river and stream edges in dry weather, and a reasonable amount of field pools, wet roads and edges of overflowed areas of all rivers and streams."

Policy.—"If the total revenue of the district ($60,000 annually) were devoted solely to drainage work, it would require at least four years to accomplish the desired end. In this event annoyance from the marsh and woodland groups would be reduced each year but practically no reduction could be made in the numbers of domestic mosquitoes. On the other hand if 10 to 20 per cent of the annual revenue were set aside for permanent improvements, a well rounded program could be carried out during which time annoyance from domestic mosquitoes could be abated and only during exceptionally wet spells would the marsh mosquitoes be a menace to comfort and then only out-of-doors.

Oiling Program.—"The experience of attempting to control marsh mosquitoes (Aedes vexans) by oiling, following excessive rainfall indicates the need for eliminating large marshes, woodland pools in the prairie sections and the channeling of streams to prevent flooding of bottom lands, as the eggs of this species lie dormant from the Summer of one year until the warm rainfall of the following year. **Elimination of the large breeding areas will make it possible to organize an oiling force which can cope with the problem of lots and road ditches and wet weather prairie pools and at the same time be large enough to control mosquitoes of the domestic group during dry weather and following normal rainfall.**

"Furthermore, it indicates that in order to meet a peak load, either a large force, trained in the use of knapsack sprayers, or a comparatively smaller force trained in the use of power sprayers, must be maintained ready for the emergency."

During 1928 a total of 1717 acres were oiled at a total cost of $12,673.81. The average time required to oil an acre for the season was 8.6 hours. The average number of gallons of oil used per acre for the season was 34 gal. The average cost per acre for the season was $7.40.

Inspection of Premises.—"House-to-house inspection for the purpose of eradicating domestic mosquitoes ranks next in importance to control of breeding in polluted rivers, streams and marshes. Mosquitoes of this type enter houses, although only a very few may cause great annoyance. It follows, therefore, that if breeding is permitted to continue unabated, mosquitoes dispersing from these small areas on one or several premises in each block may destroy the morale of the whole undertaking."

Street Catch Basins.—The street catch basin is a recognized source of mosquito breeding. It produces mosquitoes of the domestic group.

The number of mosquitoes bred in catch basins over a limited area never exceeds the number produced in polluted rivers, streams or large marshes. On the other hand the number bred in catch basins often exceeds the number bred in artificial containers on home premises. However, in the catch basin, breeding is more or less constant, while home premise breeding varies both as to neighborhood and number of po-

tential breeding places present at any one time.

The control of catch basin breeding is very necessary in that production here may be the principal source of annoyance especially in the high class residential districts from which the District receives its best co-operation. There are 20,000 catch basins in the 30 square miles of built-up area in the district. The cost per treatment with oil or mosquito repellent for the season averaged 2½ cents per catch basin.

Nineteen different species of mosquitoes were caught in the district during 1928; however, only 4 different species made up 98 per cent of the total number caught. Eighty per cent were "Aedes vexans, 12 per cent Culex salinarius, 4½ per cent Aedes trivittatus and 1.2 per cent Culex pipiens." The two varieties of Aedes making up 84½ per cent of the total are marsh mosquitoes, while the two varieties of Culex making up 13.2 per cent are domestic mosquitoes which breed in polluted water.

During 1928 $53,455 were spent in permanent improvements such as drainage operations, while $53,073 were spent in operating cost.

Remedying Troublesome Conditions in Filter

Method of Removing Hard Spots, Cracks and Mud Balls

By R. W. FITZGERALD
Superintendent Water Purification, Alexandria, Va.

IN THE water purification process much depends upon the efficient operation of the filter beds. Many difficulties are encountered but probably the most common ones are hard spots, cracks and mud-balls.

Causes of Troubles.—There are many agencies which contribute to the formation of these troublesome conditions. Improper coagulation causes the water to enter the filter unit with insufficient "floc" to form a good filter mat. This allows the fine particles of silt and mud to penetrate deeply into the sand bed. Insufficient sedimentation causes the filter to receive an over-load of turbidity and bacteria. In all probability bacterial growths in the filter help in the formation of hard spots. The same is no doubt true of algae growths. Broken or clogged strainers and underdrains serve as hindrances to proper washing of the filter. Washing filters at low velocities and for short periods of time encourages the formation of mud-balls. Cracks and fissures in the filter bed are usually caused either by improper washing or by the growth of certain bacteria which cause the filter mat to contract and break.

Effect of Hard Spots.—The effect of both hard spots and mud-balls is, first, to decrease the time of service of the unit in as much as they decrease the filtering area. Secondly, they form a hazard to the quality of the effluent in that they may serve as breeding places for bacteria or by forcing the water to pass too rapidly through the remaining parts of the filter. Cracks or fissures on the other hand let the water through the filter more rapidly but in so doing they lower the efficiency of the unit by allowing turbidity and bacteria to pass through also.

Results from Combination of Treatment.—Unfortunately there is no one remedy for these troubles. Rather, the filter plant operator must use a combination of treatments to get the desired results. The best treatment, of course, is the preventative treatment. The "floc" should be of good size in order to entrap the fine particles of silt, mud, etc. The retention time in the sedimentation basins should be sufficient to settle out a very large percentage of the suspended matrial. This, of course, will mean a very substantial reduction of the load upon the filter. Where a high bacterial load is present or where algae are found troublesome prechlorination has been found to be of considerable advantage. A good example of this is shown in the operation of the water plant at Raleigh, N. C. There hard spots and cracks in the filter mat were to a great extent eliminated by the use of prechlorination. Also at Southern Pines, N. C., the average filter service hours were nearly trebled by using chlorine in the raw water. Prechlorination has been used at Springfield, Ill., to lighten the bacterial load on the filters but no particular study was made as to the effect upon the prevention of mud-balls or hard spots. A high velocity wash is one of the best methods of keeping the filter in good condition. Some years ago considerable trouble with mud-balls was experienced at the plant at Gatun, Canal Zone. The rate of flow of the wash water was 12 in. vertical rise per minute. This rate was gradually increased until 24 in. rise per minute was attained. This increase in wash water velocity practically eliminated the mud-ball trouble. The same experience was had at Colon, Canal Zone. There the rise was changed from 18 in. per minute to 24 in. per minute, with results similar to those obtained at Gatun.

Method of Removing Hard Spots and Mud-Balls.—The most successful method of removal of hard spots is to break up the area with a pole and to give the filter long hard washes. The removal of mud-balls may be accomplished in various ways. If the filter can be put out of service and allowed to thoroughly dry out the balls will disintegrate and can easily be washed out. This method has been used at Oklahoma City when conditions permitted. The procedure is not applicable in most instances, however, due to the inability to leave the unit out of service for any great length of time. The method of removing the mud-balls by skimming them out with a long handled screen passed through the suspended sand during the wash has proven fairly satisfactory. This is the method in practice at Hannibal, Mo., and it has been used at Alexandria, Va., with considerable success. Scraping off the top layers of sand is common practice in many plants. Such practice has been highly satisfactory at Springfield, Ill. There the filters are all scraped at regular intervals. During the past several months very little trouble has been experienced from mud-balls or hard spots. This method, of course, necessitates periodic replacement of the sand removed. Another method which has been used at both Springfield, Ill., and Oklahoma City, is that of jetting the sand from one filter to another and screening out the mud-balls as it enters the second filter. This was accomplished by constructing a small wooden box into one side of which was set a 4 in. pipe leading to an adjacent filter. Directly opposite this pipe was set a fire hose carrying an inch and a quarter nozzle. The nozzle was placed about 5 in. from the pipe mouth and headed directly into it. The water being turned into the hose, sand was shoveled into the box and was carried by the water through the pipe. At the exit end of the pipe was placed a screen to catch the balls. This process was repeated in each filter unit and thus from 12 to 15 in. of sand was removed, washed and returned to the filter. This is rather a long process and is not recommended for use unless other methods fail to clean the filter.

Summary.—The chief causes of hard spots, cracks and mud-balls are: improper coagulation, insufficient sedimentation, bacterial and algae growths, and washes at low velocities and for too short periods of time.

The effects are to lower the quality of the effluent, to decrease length of filter runs, and to increase the number of washes.

Preventative treatments are: thorough coagulation and sedimentation, prechlorination, and high velocity washes. Curative treatments are: scraping, skimming, or removing and washing the sand.

Reducing Corrosion

How Staunton, Va., Treats Its New Supply

By W. F. DAY
City Manager, Staunton, Va.

FOR many years, Staunton, Va., obtained its domestic water supply from limestone springs located within the city limits. The water from this source is very hard (about 275 parts per million) and because of the possibility of pollution and of the deficient quantity of dependable flow, it was decided to seek a new source.

North River was selected as the new supply, as it provided a sufficient quantity for the estimated future consumption of the city, with little likelihood of pollution and is of a very soft quality.

The New Supply.—The location of the 125 million gallon storage dam and works in North River is about 15 miles northwest of the city, in the National Forest, the water being brought to the city through a 16 in. cast iron main, part of which is laid in a 6 ft. by 6 ft. tunnel through rock for 5700 ft.

A distribution reservoir of 3,750,000 gal. capacity, with aerators, was built two miles west of the city.

The cost of the new supply was over $800,000, and it was placed in operation in August, 1926.

About a year later we began to receive complaints of red water and iron rust particles being carried by both hot and cold water pipes into dwellings.

Sections of services and mains which were taken up for repairs showed a complete disappearance of the former carbonate lining caused by the hard water, and in its place was noticed the formation of tuberculation of the iron wherever the original protective coating or galvanizing was defective.

Treatment with Caustic Soda.—Following investigations and analyses of the water, with the cooperation and assistance of the State Board of Health, it was decided to raise the alkalinity of the water by adding sodium hydrate or caustic soda.

In January, 1928, we commenced feeding 60 lb. per day to 1,200,000 gal. of water. As it was some time, a week or more, before we could get any indication of the treatment in town, the amount was increased to 90 pounds per day.

We finally settled on 60 lb. per day, and tests taken twice daily at North River showed a pH of 6.6 to 7.2 of the raw water and 8.8 to 9.4 for the treated water. This produced a pH in the city of from 7.8 to 8.4.

The complaints became less frequent, and the cold water pipes delivered clear water, unless the circulation in the mains was very poor, and allowed the water to remain standing for some time in the pipe. The hot water still gives trouble; depending on the temperature to which it is heated, and also upon the condition of the boiler or heater; fixtures that are old or of poor quality offer less resistance to the corrosive action of the water.

The difficulty next appeared of stoppages in the services and house pipes, caused by the tuberculation restricting the flow of water. This was particularly noticed on the hills where the pressure is lower and in ½ in. pipes of inferior material that have been installed a long time.

In October, 1928, a firm of consulting engineers in Baltimore was employed to investigate the corrosion problem and recommended proper steps to reduce the trouble.

The New Treatment Plant.—The report was received in December, and recommended the construction of a treatment plant to be built at the North River works, in order to protect the supply main to the city. At this plant the water might be treated with lime, caustic soda or sodium silicate, or a combination of them, as proved most beneficial.

The plant is to consist of a concrete building 20 by 30 ft. and a double sedimentation tank 34 by 53 ft. and 11 ft. deep, all designed for the ultimate flow of 2½ m.g.d.

In the building are to be placed a solution tank, 9 ft. in diameter, an automatic feeding device, a mixing channel and storage space for chemicals. An overshot water wheel operates the agitators in the solution tank. Head for operating the water wheel is to be obtained from water behind the dam. Tail water from the wheel flows into the mixing channel

Dam on North River and Part of Reservoir, Staunton, Va.

and thus would not be wasted. This plant is estimated to cost $14,000.

Plant Operation.—The plant is being built about 100 feet from the dam, and will operate as follows: a valve in the supply main will divert the water through a mixing channel in the chemical house, where a pre-determined amount of lime solution will be thoroughly mixed with the water.

The dosed water then flows quietly through a sedimentation basin of an hour's capacity, during which time inert chemicals and sludge settle out, the clear water in the meantime flowing continuously to the city. The water wheel is used to stir the lime or other solution in the solution tank, so that uniform strength of chemical is maintained.

The sedimentation tank is divided so that in cleaning it would not be entirely out of operation. This tank is covered with a concrete roof to prevent freezing or the admission of leaves and other trash.

Once a day the caretaker at the dam will put a weighed amount of chemical into the solution tank, filling it up with water and then inspecting the working parts, such as the water wheel, automatic measuring device, etc.

Removing Corrosion from Service.—This treatment plant is intended to reduce the future corrosion of the distribution system and house pipes, but will not remove the corrosion and stoppage of the services now existing.

This is another problem. We have been experimenting with several methods of doing this, and we have found that a 10 per cent solution of sulphuric acid, if left in a corroded service line for 4 or 5 hours, will loosen the tuberculation and by blowing compressed air through the line it will be fairly well cleared. Care has to be taken not to leave the acid in the pipe too long, for not only will the corrosion be loosened, but holes will be eaten in the pipe as well. Of course we are careful to neutralize the acid left in the line before turning the water back in the house.

We recently have tried with good results the removal of the corrosion by introducing dry steam into the service line, and as the pipe expands faster than the corrosion attached to it, the corrosion is loosened and may be washed from the line.

The treatment plant at North River is being built by city forces, and we expect to have it completed and in operation by August 1st.

Acknowledgment.—The foregoing is a paper presented April 26 at the First Virginia Conference on Water Purification and Sewage Treatment.

Traffic Engineers.—Twelve cities and one county now have traffic engineers.

Method of Testing Soil for Westfield Dam

Soil tests in connection with the construction of the Granville earth dam for the city of Westfield, Mass., were facilitated by the use, in the field office, of a device for measuring the capillary rise of water in the samples of soil. The method involving the use of this device was worked out by Dr. Charles Terzaghi of Massachusetts Institute of Technology.

The device, which is illustrated in the accompanying drawing, consists of a small tank to hold water and support a set of capillary tubes, an irrigator tank and a set of tubes. In making a test, the sample of earth is first dried, care being taken not to burn the material. The tubes are filled with the dry material in layers and compacted. They are then set into the tank and water from the irrigator tank is fed to the tank containing the tubes. The dam at the end of the tank holds the water to a level which will keep the bottom of the tubes always submerged. The tubes are graduated, or a scale is erected in back of them. The time is taken when the tubes are first set in the water and, as the water rises in the soil, readings are taken every five minutes. These readings are plotted on a diagram which gives the relation of the capillary rise of water in the soil to the coefficient of permeability.

Numerous tests were conducted previous to construction. The weight and volume of each sample tested are measured. Knowing the specific gravity of the material, the volume of voids and the void ratio are readily computed. While the theory underlying the process is rather involved, the application of it is very simple. Taking a set of samples, testing and recording the results requires the time of only one man about one-quarter of a day. The suitability of a material for use in the fill can be determined within an hour.

Automatic Device Prevents Freezing in Pipes

A device to prevent the freezing of water in pipes, not dependent upon thermostatic action, has been exhibited recently. A brass freezing chamber is employed to spread the stream of water into a thin sheet which is frozen at a temperature 10 degrees higher than that which would congeal the water in the pipes. In freezing, the thin sheet of ice exerts pressure against a metal diaphragm which opens a drain valve and empties the pipes of water. With the advent of milder temperatures, thawing of the ice releases pressure on the diaphragm, closes the drain valve, and permits water to flow again.

Sawdust Streets Built in Lumbering Town

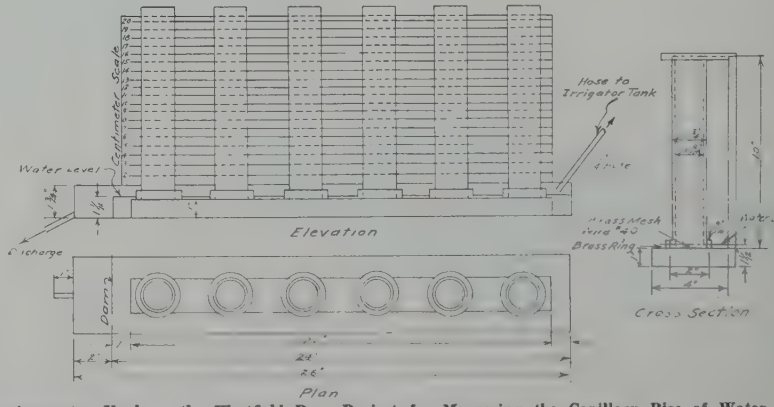
When the citizens of Dorris, Calif., a lumbering town in Siskiyou County, demanded relief from the muddy condition of the streets, sawdust was suggested as a paving material. Several tons were secured from nearby sawmills and distributed over the streets of the town. After the sawdust had packed down, it was found to give an excellent roadway surface.

Recording Meter Readings by Photography

Where tests are being run which require frequent readings of a number of instruments, or where simultaneous readings of a number of meters, etc., are required for purposes of record, it will be found convenient to assemble all of the instruments on a single board and photograph the group at the necessary intervals. Reference to the photographs will furnish any desired readings.

Drainage Yield, Wanaque Watershed

Filling of the 27,800 m.g. Wanaque reservoir of the North Jersey District Water Supply Commission in less than a year gives a daily average yield for the drainage area of 94.4 sq. mi. tributary to the reservoir of 1.1 m.g. per square mile of drainage area.



Apparatus Used on the Westfield Dam Project for Measuring the Capillary Rise of Water in Samples of Soil

Control of "Unaccounted-For" Water

Results of Tests and Studies in a Number of Cities

By W. C. MABEE
Chief Engineer, Indianapolis Water Co., Indianapolis, Ind.

UNACCOUNTED-FOR water is defined by the Water Works Practice Manual as "that portion of the water flowing into a distribution system which is not delivered to the consumer." Water waste is defined as "water which is not drawn to serve effectively a useful and legitimate purpose."

Confusion in Classification.—There is often confusion as to the meaning of the term "unaccounted-for water," as will readily be discovered by studying the answers received to the questionnaire sent out by the Indianapolis Water Co.

There is a tendency to group water allotted to public uses, such as fire fighting, flushing streets, sewers, unmetered services, under-registration of meters and underground leakage into a lump and call that unaccounted-for water. Much of this so-called unaccounted-for water is delivered to the consumer and is, therefore, in the language of the definition before quoted accounted for, having served effectively a legitimate purpose.

Water waste is another matter and it may or may not have been measured to the consumer.

If Indianapolis, for instance, were to report its unaccounted-for water as embracing water not metered but used for public purposes, plus leakage and unauthorized use the report would read 18 per cent of its total pumpage; whereas, if a reasonable allotment of legitimate use to public and other known uses is made, confining the answer to the definition above given; that is water not delivered to the consumer, the percentage is 10.7, approximately.

It seems, therefore, that water that can reasonably be accounted for as having been used by the consumer, whether it be the fire department, public street sprinkling, flushing of sewers, water for swimming pools, public parks and municipal buildings or other legitimate purposes, is not unaccounted-for water although frequently classified as such.

No water works system can reasonably be expected to account for all the water that enters its distribution mains. There are unavoidable losses due to underground leaks that it would not pay to uncover and repair, under-registration of meters that in some instances would cost more to keep operating at an efficiency of 100 per cent than the value of the water saved would be worth. There is an economical efficiency beyond which there would be no profit.

On the other hand there are large losses in underground leaks, under-registration of meters and unauthorized uses that could very profitably be recovered. Some of these losses which have recently come to my attention I will touch upon later.

The Economic Limit.—An occasional check up should be made for unaccounted-for water to keep it within bounds.

Unaccounted-for water that exceeds an economic limit is an economic waste; the money value of which will depend upon local considerations, but which will in most instances represent a substantial loss of revenue.

Water that has been purified and pumped represents invested capital in plant, in operation, in materials, in supplies and in maintenance. This represents its value and it should be conserved as other commodities are conserved.

If, by means of water waste surveys, water prevention, more accurate meter measurements, or other means of decreasing consumption without restricting legitimate use, a saying can be effected, that conservation of the water supply means deferring the time when additional supply will have to be provided involving a corresponding outlay for boilers, pumps and buildings.

By the term "economic limit" in implied in the language of E. K. Wilson, chief engineer of the Pitometer Co., in referring to unaccounted-for water and under-registration of meters "that point beyond frequent testing brings in returns less than the cost of the work; probably 85 per cent would be a fair figure."

E. D. Case, vice-president and general manager of the same company, commenting on this same subject in a recent letter to the writer, says: "It is my opinion that every metered city should account for at least 85 per cent of the total consumption, and it is possible by present up-to-date methods to increase this figure to the economical limit."

There is, of course, no hard and fast rule that will apply to all communities alike, and the economic limit in one place would be a different figure in another, depending on local conditions.

Separation of Consumption.—For years engineers have been advocating a separation of consumption into at least two divisions; one being industrial and the other domestic. More divisions are preferable, but these two are indispensable if we are to compare consumption figures, however, having acquired the habit of reporting consumption per capita as one figure without reference to the industrial consumption, we go on reporting consumption in this unscientific manner.

We had occasion recently to study the distribution of water in Indianapolis, where we are about 50 per cent metered with reference to ascertaining the amount of unaccounted-for water that we were pumping into the system and which at first glance seemed to be a large part of our pumpage. As a preliminary step in making this study we decided to compare our consumption of water with other cities and to that end sent out a questionnaire to several hundred cities, large and small, and widely separated.

These answers have been tabulated and show these data in a condensed form, arranged alphabetically by groups according to population, which is made part of this paper.

Analysis of Pumpage at Indianapolis.—The next step was to analyze our pumpage by subdividing it into five groups as follows:

(1) Industrial, (2) Commercial, (3) Domestic, (4) Public and (5) Unaccounted for; tabulating the annual and daily consumption in million gallons and reducing these to gallons per capita per day and to per cent of total pumpage.

The service was itemized as follows:

First — Industrial Use. — Industrial service included railroads, factories, utilities, manufacturing plants, dairies, ice plants, laundries, etc.

Second — Commercial Use.—Stores, offices, clubs, hotels, office buildings, hospitals, schools, colleges, theatres, churches, barber shops, garages, etc.

Third—Domestic Use.—Apartments and residences.

Fourth — Public Use. — Municipal buildings, parks, play grounds, swimming pools, fire protection, fountains, parkway sprinklers, building construction, flushing streets, sewers, water mains and ditches.

Fifth—Unaccounted-for Water.—Unavoidable leakage in mains and services, unauthorized use of water, extraordinary meter slip and water otherwise unaccounted for.

A minimum allowance for under-registration of meters was made for each division where service was metered.

Considering the questionnaire so far

as Indianapolis is concerned our studies disclose the following:

Daily per capita consumption	89.3 gal.
Average daily pumpage	34.83 M.G.D.
Percentage of pumpage registered on customers' meters	56%
Per cent of all services metered	45.8%
Per cent of all domestic services metered	41%
Per cent of industrial and commercial services metered	96½%
Per cent of pumpage unaccounted for	10.7%
If underground leakage and unauthorized water only is considered.	
If unmetered public uses, under-registration of meters, underground leakage and unauthorized uses are combined	18%
Under-registration of meters assumed as about	5%
Frequency of meter testing; at least every six years for small meters, yearly for large meters.	
Have studies of unaccounted-for water been made?	Yes.

These studies disclosed the percentage given, which from an inspection of the tabulation does not appear to be an unusual quantity of unaccounted-for water. No steps have been taken to decrease the amount of unaccounted-for water as yet.

Comparison of Consumption.—Statistics are apt to be misleading unless all of the facts and conditions are known.

To arrive at a comparable comparison the industrial and commercial uses must be excluded from the total, because of the wide variation in industrial use of water in the different cities. The remaining consumption represents public use, domestic use and unaccounted-for leakage or other loss.

In Table I we have been unable to check up average daily pumpage and per capita consumption with population figures in many instances, and have observed a lack of standard practice in the matter of reporting under-registration of meters and in unaccounted-for water.

In general, I believe that most water works superintendents consider unaccounted-for water the difference between the quantity of water metered to consumers and the quantity entering the distribution system. Unaccounted-for water may be classified in the following divisions:

First: Pump slip.
Second: Underground leakage.
Third : Unauthorized use.
Fourth: Under-registration of meters.

Pump Slip.—It has frequently been found that, in the absence of a master meter, the plunger displacement of reciprocating pumps has been taken as the measure of water entering the distribution system the quantity has been grossly exaggerated. Instances have been known where the discharge from a pump has been completely closed and the pump has gone on churning.

Allowances for pump slip are sometimes taken as low as 2 per cent, usually as 4 or 5 per cent and it is not unusual to find upon careful tests that pump slip may far exceed 5 per cent and may be as much as 30 per cent of the theoretical displacement of the pump plungers.

So that in considering data presented, allowance must be made for the source of the information and the judgment of the person supplying it.

Underground Leakage.—Underground leakage usually represents the largest element of unaccounted-for water. It occurs at pipe joints, service connections, broken pipe or broken services, at blow-off connections or in valves. It is caused by poor workmanship in making joints when pipe was laid or has developed from settlement, or injury occurring after pipe was laid and is not infrequently due to electrolysis, sometimes caused by the corrosiveness of the soil and often caused by stray electric currents leaving the metal structure.

While it is possible to make pipe joints absolutely tight, a certain amount of underground leakage is considered unavoidable. Engineers often specify a tolerance of 200 or 300 gal. per inch diameter per mile of pipe in 24 hours in new systems. The Pitometer Co. considers 3,000 gal. per mile of pipe per day a reasonable allowance for unavoidable underground leakage, after all reasonable precautions have been taken to stop leaks.

There are many water systems, no doubt, that have been fortunate enough to keep underground leakage below this allowance, but there are many more that are not so fortunate. For instance:

The City of Chicago in 1926 tested 66 miles of mains in advance of street paving, and found underground leakage of 10,000 gal. per day per mile; 90 per cent of which was stopped.

The City of Philadelphia, now conducting a pitometer survey for water waste, found underground leakage on a section embracing 626 miles of pipe, amounting to 10,250,000 gal. per day, or in excess of 16,000 gal. per mile of pipe per day, which will, as a result of this survey, be reduced to a minimum.

During the past eleven years Chicago has discovered underground leakage on 668 miles of pipe, which has averaged about 13,000 gal. per day per mile of pipe.

The City of Cincinnati, in 1925 and 1926, found and stopped leakage amounting to 5,000,000 gal. per day, or 10 per cent of their total pumpage. The survey covered about 800 miles of mains which is equivalent to 6,250 gal. per day per mile of pipe.

The City of Detroit located and stopped leakage in mains and service as a result of a pitometer survey in 1919 and 1922 amounting to 9,500,000 gal. per day over 1,151 miles of mains, which is equivalent to 8,300 gal. per day per mile, since which time the City of Detroit has organized its own pitometer department and carry on continuously.

Underground leakage such as that just described was interceptible on the surface; the leaks were of such a character that the water was readily dissipated into the soil or into the nearest sewer without a showing on the surface. One superintendent wrote in that he was able to discover leaks by observing after a snow storm the wet places in the snow and would mark the spots for future attention. Others inspected sewers periodically to discover abnormal flows which would indicate leaks or excessive waste.

Underground leaks, beginning in a small way, may, after the lapse of time assume substantial size and cause considerable damage by undermining pavement. A break in a water main may exist and continue for an indefinite period, discharging into a sewer manhole and may never be discovered unless a search is made for just such a condition.

Too often service pipes are installed in the same trench, as the house sewer. This is an invitation for trouble, as a leak may occur on the service pipe and the water escape into the sewer without detection.

The aquaphone, or listening device, is often employed to locate leaks. It is often difficult to detect underground leaks by this method in a large city, because of the noise of the busy street. Blow-off connections into streams or sewers may have been left open. Stuffing boxes of valves are frequently found leaking and in many cases are difficult to prevent. The kind of packing used has a large influence on leaks of this character.

Submarine leaks can be discovered by forcing compressed air into the pipe and observing bubbles on the surface.

Longer lengths of pipe are now being advocated to reduce the number of joints and consequently the quantity of leakage; one-third of the joint leakage can be prevented by the use of pipe in 18-ft. lengths.

Results in Various Cities.—One of the most enlightening answers to the questionnaire came from the city of Akron, O., which is 100 per cent metered, where the water department has evidently been studying this question of "unaccounted-for flow" for the past seven years. The percentage of un-

Table I—Composite Water Consumption of Cities Responding to Questionnaire

Number of cities	Total population of cities	Per capita consumption per day gallons	Per cent of pumpage or supply entering distribution mains registered by individual meters	Water alloted to Unmetered Public Use Underground leakage, Under-registration of meters, Unauthorized use or otherwise unaccounted for
160	25,394,427	98.67	.....	.....
123	.....	.....	71.68	.....
121	.....	.....	.....	24.72

Average 158,715.

accounted-for flow for this period averaged 23 per cent, but during the last four months of 1927 had been reduced to 12 per cent of the total pumpage. This reduction was brought about by "conducting a continuous street survey covering hydrant, valve, curb cock, sill cock, and general surface inspection."

Unaccounted-for flow in Akron "includes illegal use of water, leakage, street flushing, testing, sewer flushing, water main flushing, construction, fire fighting and meter under-registration. In Akron practically all new mains are laid by water works force account. "Construction specifications have been changed to require new mains to pass a leakage test of less than 100 gal. per inch-mile per 24 hours."

"Results obtained average less than 30 gal. per inch-mile per 24 hours before actual acceptance." Here, then, is a shining example for the water works fraternity to emulate.

Baltimore, with 19 per cent of its domestic accounts and 100 per cent of its industrial and commercial accounts metered reports 18.4 per cent unaccounted for and allots 8 per cent of this to municipal use and 10.4 per cent to waste (leakage?).

Chicago has a daily per capita consumption of 292.5 gal. and records 31.4 per cent through individual meters, which supply 16.1 per cent of the services. The city engineer reports 10 per cent of the pumpage chargeable to underground leaks, pump slip, etc., and about seven per cent of this to underground leakage.

Cincinnati, which meters all revenue-producing consumption, accounts for 75½ per cent of the total. Water used for fire protection, street cleaning, public buildings, parks, etc., is not metered.

Cleveland, which is 100 per cent metered, accounts for 75½ per cent through meters.

Kansas City, Mo., which is 84.6 per cent metered, accounts for 75 per cent of its pumpage through meters, estimates free water at 12 per cent, waste, leakage and under-registration of meters 10.1 per cent and flat rate domestic 2.9 per cent.

New Orleans delivers 47.9 mgd into its distribution system (110 gal. per capita per day), of which 68 per cent is recorded through consumers' meters. All of the domestic accounts are metered and all of the industrial and commercial accounts except fire-sprinkler connections.

New York City has a daily per capita consumption of 144 gal., uses 867 mgd. and records 26 per cent through individual meters. Three per cent of the domestic accounts are metered and 21 per cent of industrial and commercial. Forty-two per cent of total municipal supply to city is considered unaccounted-for flow and is defined as follows:

"Leakage from plumbing fixtures of domestic consumers and free users is estimated to be 25 per cent of total supply to city; meter slippage 6 per cent of total supply; underground leakage from water mains and service pipes 11 per cent of total supply."

The following comment is made respecting efforts to check water waste:

"House to house inspections have been made to stop leakage from plumbing fixtures as temporary expedients to conserve supply during time of shortage of water. The saving made during such inspections is lost in about two years' time. Underground waste work has been carried on for a number of years with excellent results, but the size of the force engaged in this work has been too small to cover the city in a systematic manner."

Washington, D. C., reports having located and stopped underground leakage amounting to 40 million gallons daily, the daily per capita consumption is now 137 gal. and the total consumption 68.7 mgd., of which 44.2 mgd. is recorded through individual meters; 85 per cent of all water services being metered. No record of unaccounted-for water is kept, due to unmetered use by federal and district government.

Unauthorized Use of Water.—There have been instances where water has been taken from fire-sprinkling connections, from services and from mains and not paid for until discovered by the sleuths of the water department. Sometimes this illegal use of water is unintentional, accidental perhaps, but no such user of unauthorized water will admit that water was taken with malice aforethought.

The illegal use of water is not a recent practice. It was known and practiced in Rome several thousand years ago.

Under-Registration of Meters.—There is considerable difference of opinion touching the subject of unaccounted-for water as affected by under-registration of meters and it is hardly to be expected that there would be an agreement on this subject since the conditions surrounding the standard practice of different communities respecting meters vary so widely.

There is need for standard practice rules and regulations governing meter testing inasmuch as the accuracy of meters affects "Unaccounted-for Water." Some cities have adopted definite testing schedules. Many cities remove and test meters when they stop functioning or when there is a suspicion that the meter is not properly recording flow or when "marked variations occur," "ten years on the average," "when they stop." In general the period set for testing meters, where a rule is followed, appears to be five years. This average was obtained from information supplied by large number of cities which had been circularized.

Acknowledgment.—The above is an abstract of a paper presented at the annual convention of the Indiana section of the American Water Works Association.

Municipal Uses of Water at Springfield, Mass.

The following table from the 55th annual report of the water commissioners of Springfield, Mass., shows the municipal uses of water in that city in 1928. The amounts and quantities shown are for mean year periods. Unmetered quantities in gallons are estimated from amounts, on basis of 6 2/3 ct. per 1,000 gal.—or equivalent of 5 ct. per 100 cu. ft.

Classification	Amounts	Gallons	
*Schools	$ 7,834.70	117,088,100	
*Public buildings (not schools)	4,040.55	60,450,500	
*Public Parks	2,694.40	40,310,900	
*Public playgrounds	466.28	7,921,500	
†Building purposes (streets and engineering department)	477.25	7,158,700	
†Sewer department (flushing)	4,114.03	61,710,500	
*Snow removal (via sewers)	1,232.51	18,487,700	
†Street washing and sprinkling	2,363.15	35,447,300	
†Drinking purposes (for animals)	60.00	897,700	
Total of above	$23,282.87	349,472,900	
Fire hydrant service	61,750.00‡	At $25 per hydrant	
Total municipal use	$85,032.87	(as per registrar's report)	

*All metered. †Unmetered. ‡Not reducible to quantities.

The water commissioners comment as follows on the above figures:

"The foregoing total amount of $85,-032.87 represents a portion of the accrued earnings of the water-works public service enterprise (but at low values) just as much as do the revenues charged to and collected from all private consumers. For proper accounting purposes this amount has to be charged annually to the municipality on the books of the water-works and then charged off as uncollectible, because payment therefor is prohibited by city ordinance."

Progress of the City Manager Plan.—The city manager plan is now in effect in a total of 383 cities in this country, and in 16 cities of Canada. Michigan leads all states in the number of cities under the plan, having 44; Florida follows with 39, California with 33, Texas with 31, and Virginia with 25. Ohio, while having only 19 cities under the plan, has the largest number of people living under this form of government by virtue of its larger cities under this form of government.

Trickling Filter Dosing

A Simple Dosing Apparatus

CONSIDERABLE trouble is experienced in dosing small experimental trickling filters at definite rates and in securing even fairly uniform discharge over the filter area. With a smaller area than served by one nozzle in a large plant it is desirable to reduce the rate of flow through a nozzle, and this adds to other troubles encountered. A simple apparatus that gave satisfactory results is described as follows in Bulletin No. 26 of the Illinois State Water Survey by G. C. Habermeyer and H. L. White.

The apparatus is shown in the sketch. Sewage is pumped into a half barrel placed several feet above the surface of the filter. From this half barrel a short pipe carries sewage to a dosing tank, the top of which is about level with the bottom of the barrel. An overflow pipe is connected through the bottom of the half barrel. By changing nipples on the top of the overflow pipe, the sewage level can be held at any desired elevation, so as to give any desired rate of flow into the dosing tank. It was necessary to clean the short pipe from the half barrel with a test tube brush, daily.

Sewage flows from the dosing tank to the filter through a siphon, a vertical pipe, a trap, and a pipe with a slight slope upward to the nozzle. Siphons and traps of small pipe, with siphon auxiliaries, were tried and discarded. A bell consisting of a 4-in. pipe cap is now used on the siphon.

One auxiliary that was tried with the pipe siphons and also with the bell was a trap of ¼-in. pipe attached to the top of the siphon. This trap was nearly as deep as the main trap and was filled by the sewage flowing into the dosing tank. It was expected that this would give sharp start and stop to the siphon and greatly reduce the quantity of air discharged through the main trap to the filter and thus give more uniform discharge. Results secured with this very small auxiliary were not satisfactory, and it was discarded.

The auxiliary now used consists of a trap of ¼-in. pipe screwed into the side of the bell of the siphon. A detail of the trap and bell is shown in Fig. 1. When the sewage level goes below the top of the outlet pipe while the tank is discharging, sewage is siphoned under the bell until enough air is drawn in to break the siphon. The auxiliary trap is placed at such an elevation that the sewage is drawn from it by the suction created by the siphon, just before air is drawn below the bottom of the bell. The siphon breaks sharply, since the ¼-in. pipe admits air into the bell after the bottom of the bell has been covered by incoming sewage. When the auxiliary trap is not used, the bottom of the bell is covered—by the sewage coming and the sewage falling from inside the bell—before the bell is completely filled with air, and the siphon does not break sharply.

In order that, with the dosing tank nearly empty, sewage could be sprayed onto the central part of the filter at a rate less than the average rate of inflow into the dosing tank, a throttling valve was placed against the end of the inlet pipe into the dosing tank. The valve was operated by a float in the dosing tank as shown in Fig. 1. A wire from the float passed up over a pulley and then down to the valve. As the sewage level lowered when the tank was dosing, the float gradually closed the valve. This reduced the rate of inflow sufficiently to permit the siphon under the bell to break. The valve seat was made uneven purposely, so that a small stream of sewage flowed from the pipe even when the valve was closed. This allowed sewage to flow into the tank when the dosing period was over, thus raising the sewage level sufficiently to open the valve and fill the tank again. This throttling device was discarded because clogging prevented uniform operation, because it was difficult to determine the amount of sewage applied to the filter, because the long time the valve was held nearly closed gave a long time between doses to the filter, and because it was found that the lowest rate of flow from the dosing tank through the nozzle was greater than the average rate of inflow, so that throttling the inflow was not necessary.

A dosing tank was then designed after some preliminary experiments with a barrel. In the preliminary experiments the relation between the elevation of the water level in the barrel above the nozzle, or the head on the nozzle, the rate of discharge, and the distance from the nozzle to the area that was being sprayed, were obtained. Nozzles used in the first tests discharged at a higher rate than desired. The capacity of a Worcester nozzle was then reduced by fastening over the orifice a brass disc with a small circular opening. The nozzle clogged on the first discharge but seldom clogged thereafter. With a nozzle chosen, the proper elevation of the top of a dosing tank to spray to the outer edge of the filter, the elevation of the bottom of the tank to spray close to the center of the filter, and the shape of the tank, were determined. For convenience in making these determinations, radii of the filter were divided into fourths and marked with nails. Water levels in the dosing tank were marked when the spray was to the outer edge of the filter, to three-fourths the radius, to half the radius, and to one-quarter the radius. The relative filter areas between the points marked on the radii were seven, five, three, and one; and, with due allowance for the constant inflow to the dosing tank, this gave the proper relative capacity of the parts of the dosing tank between the marked points. The relative areas, expressed in percentage of the total, were 44, 31, 19, and 6; and the percentage of the total sewage applied to these areas, with the tank designed and with all connecting pipe clean, during two tests, averaged 55, 36, 9, and 0, respectively. The outer 75 per cent of the area was dosed higher than the average. Much of the remainder of the spray fell at a little less than half the radius from the center, giving about 10 per cent of the area sprayed at about normal rate.

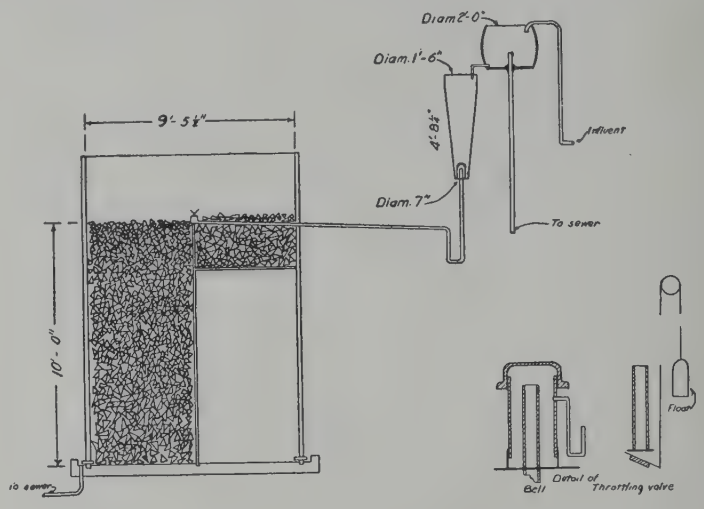


Fig. 1—Details of Dosing Apparatus

As the pipe became dirty the spray fell a little nearer the center and average conditions were better than during any one test. It was considered advisable to have little sewage fall on the inner 6 per cent of the area, as it would fall on or close to partition walls in the filter and flow down the walls.

The sprinkling filter was started on Nov. 30, 1926. Its area was .0016 acres. During the first month of operation the rate was slightly low, and stops were more frequent than later, giving a net rate of 1,800,000 gal. per acre per day. This was increased the next month (January) to 1,900,000 gal. per acre per day; and from that time until Sept. 15, 1927, excepting for a shut down of about 67 hours due to flooding the experiment station by an adjacent stream, the quantity filtered gave a net rate of practically 2,000,000 gal. per acre per day.

Lengths of Filter Runs

Operating Data for Fredericksburg, Va. Filter Plant

By R. J. LEVEQUE
Superintendent of Filtration, Fredericksburg, Va.

THE figures which appear in the space on the operating report devoted to filter runs, always serve as interesting material for study, since these figures are very often indicative of the efficiency with which the plant is being operated, assuming of course that conditions governing any particular plant are known.

The Fredericksburg plant is not quite two years old. Putting the new plant into operation meant that the usual experimental stage would have to be gone through, records kept and data compiled to serve as reference material and operating guides for the future. When records of these runs are compared, they show on the average a steady gain.

How Improvement Was Effected.—This improvement might be attributed to several things but I think that the greatest factors for this increase were the substitution of soda-ash for lime the changing of the point of application of chemicals to the raw water, the latter being the more important.

Formerly the chemical feed pipes injected the coagulants into a T on the discharge side of the low service pumps. This T was located closer to the discharge into the left basin than it was to the right basin. With both basins being supplied by this raw water line, it naturally followed that the left basin being nearer the point of application, received the bulk of the applied water. The water going to the other basin as a result was undertreated. It was impossible to get an even distribution, consequently proper settling could not take place. This increased my filter loads and shortened my runs considerably.

The coagulants are now applied 15 ft. ahead of the raw water pumps. The results are nothing short of marvelous. A thorough mix is obtained in passing through the pumps and into a pair of splendid mixing chambers of the "around the end type." Both basins are now equalized in the amount of treated water received and we are now able to utilize and reap the benefits from our rated settling period.

Importance of Jar Test.—With this handicap removed, I have been able to lengthen my filter runs still further by devoting much time and attention to the "floc." As good filter performance is greatly dependent on the condition of the floc, I would like to stress the importance of the jar test, especially to the operator of the small plant. It eliminates guesswork. Very often a floc will look good in the basins, and, yet many times it is possible to obtain a still better one. Dipping up a few jars of the coagulated water and changing the proportions of the chemicals makes it possible to observe and compare the results of each altered dosage. Frequently the best settling takes place in the jar to which the least amount of chemicals have been added.

In my daily tests I take a pH of the jar contents giving the best results and hold the water going to the basins at this optimum. At Fredericksburg the best coagulation seems to be effected at the range between 6.6 and 7.0.

Conditions Reducing Filter Runs.—Some valuable experience was gained last year in coping with conditions that tended to reduce filter runs. The first was algae. No growths appeared in the basins, and the raw water had a turbidity of less than 15 parts per million and the only indication that anything was wrong was a stringy floc and a pronounced grassy odor to the water. A chance walk up the canal to the dam where the water was calm, revealed the trouble. The surface was coated with a green scum. This year I was able to check this with copper sulphate at the first appearance of the stringy floc and instead of having prolonged short runs, as before under similar circumstances, this time in two days, I was able to start the filters back to normal runs.

The second condition was air-bound filters, especially noticeable in the spring and fall of the year. My gauges did not show any great loss of head and yet the filters would not pass their required amount of water. A careful check-up for leaks in the valve-stem packings, and the tightening of any that were doubtful relieved the condition somewhat, but I presumed that this condition was caused more by the sudden temperature changes in the water. My method of getting around this situation, was to close the effluents on any ailing filters for a few minutes, which permitted the air to rise to the surface. Using the re-wash after this and then putting the filter back into service did away with the necessity for washing for several hours.

Use of Re-Wash Valves.—I have a few words regarding the proper use of the re-wash valve, after a filter has been washed. Using this valve from 3 to 10 minutes at this time not only will lengthen a filter run but will also improve the quality of the effluent. I have noticed of late that a filter washed just prior to shutting down the plant for the night, gives from two to five hours longer run than those washed at any other time. The natural settling that takes place over night seems to form a splendid unbroken mat over the sand bed, which apparently, is even better than the one formed by using a slow rewash, due perhaps to the fact that no fine particles are drawn down into the bed. Of course in the larger plants, extra units make it necessary to return a filter to service immediately after washing, but I am sure that if any small plant can spare a washed filter, if only for thirty minutes before putting it back into service, thus permitting a natural formation of the mat, that their filter runs will be materially increased.

Supplementing these operations, it is of course understood that the proper care of filter beds must be undertaken and that they must be frequently probed for hard spots, cracks and dead areas, together with the inspection of the sand surface for mud balls.

Cleaning Basins.—The frequency with which a coagulating basin should be cleaned is dependent upon how much suspended matter the raw water contains, how much coagulant is used, how good the floc secured and other factors. The time for cleaning is easily observed by old "floc" being raised up from the bottom of the basin and carried over onto the filters, the appearance of gas bubbles, and by measuring the depth of the sludge. For this latter method I attached tin cans to a pole at intervals of 6 inch for a distance of 6 feet. The uppermost can containing sludge gave an approximate depth of the settled matter.

We cleaned our basins for the first time, six months after the plant had been in operation. The accumulation of sludge was so great that to wash it out by ordinary methods was deemed inadvisable for reasons which are here given.

The plant at Fredericksburg is situated in a hollow. A ditch drains this lowland, emptying below the town. This same ditch is used by us as a drain, the plant being erected directly over it, and to empty this great amount of sludge into the run, would have clogged underneath the plant.

A force of men was assigned to remove the greater portion with shovels and buckets. This proved a very laborious task and four days were required to clean both basins. On that basis, washing basins proved expensive, and so it was decided to wash them out in the future, at regular intervals of from two to three months.

This enables one man to accomplish the job in one and a half hours.

The design and construction of our

sedimentation basin at Fredericksburg makes the cleaning a short and easy operation. Due to the pronounced slope of the floor of the basin to the draining gutter, a great deal of the sludge is washed out during the draining process, which reduces considerably the amount to be washed out with the hose.

When the water was drained down to about 6 in. above the sludge we commence loosening the sludge in the farther end of the basin with the hose. By the time the draining is finished, one end of the basin is practically cleaned. As different batches of sludge are loosened by the hose, I open the connecting gate between basins, allowing water from the other basin to come in and fall over the weir, the entire width of the basin. This keeps the sludge thin, and enough water is used to carry the loosened sludge down over the whole area of the basin.

Washing more frequently has proved more economical for us and clean basins are assured at all times.

Acknowledgment.—The above paper was presented April 25 at the First Virginia Conference on Water Purification and Sewage Treatment.

Chlorinated Copperas as Coagulant

Experiences at Chickasaw, Mobile County, Alabama

By A. CLINTON DECKER and H. G. MENKE

Respectively, Sanitary Engineer, Tennessee Coal, Iron & Railroad Co. and Chickasaw Utilities Company, and Assistant Sanitary Engineer, Alabama State Board of Health.

THE Chickasaw water works system supplies water to the towns of Chickasaw, Ala., and Prichard. Chickasaw is a town built by the United States Steel Corporation during the war to provide housing facilities for the employees of the Chickasaw Shipbuilding Co., a subsidiary of the corporation, and is located about seven miles north of Mobile. The present population of Chickasaw is about 2,000. The town of Prichard is an incorporated municipality having a population of approximately 1,500. The water works plant at Chickasaw was built by the steel corporation in 1918 to supply water for domestic and industrial purposes for the village and plant.

The Water Works.—About 18 months ago, the Alabama Water Service Co., with general offices in Birmingham, secured a franchise for supplying water to the town of Prichard and negotiated a lease with the Chickasaw Utilities Co. for the operation of these properties to supply water to Chickasaw, Prichard, and adjacent territory. The plant at this time consisted of a pumping station, plain sedimentation basins of 1,000,000 gal. capacity, an elevated steel storage tank of 200,000 gal. capacity, and a very complete distribution system. The source of supply for this plant was Eight Mile Creek which originates in springs and flows through heavily cypress wooded territory. The water has a color ranging from 40 to 130 parts per million; the turbidity normally varies from 3 to 25 parts per million and on very rare occasions reaches 50 parts per million; the alkalinity ranges from 2 to 5 parts per million; and the pH ranges from 5.5 to 5.9. The bacterial count is usually low —mostly under 100 per cubic centimeter. In the original plant, provision was made for chlorinating the water as it was drawn from the settling basins and pumped to the elevated storage tank.

The filtration plant is an entirely new unit of the Water Works System at Chickasaw. The construction of this unit was begun the first week in January of this year and completed April 6th.

Because of the possibilities which preliminary studies had indicated as being presented at this plant for successful use of "chlorinated-copperas" as a coagulant, the authors invited L. H. Enslow, of the Chlorine Institute, who had first suggested the use of this coagulant at Chickasaw; C. Arthur Brown, Chief Engineer, Bureau of Water Purification, American Steel and Wire Co.; C. P. Rather, Chief Engineer of the Alabama Water Service Co.; and G. R. Kavanagh of the Wallace and Tiernan Co., to be present during the experimental operation of the plant from April 9th to 19th, inclusive, for observation and such suggestions as they might make looking to the development of this process, or modifications thereof, as would best meet conditions presented by the soft water of low turbidity and containing considerable color of vegetable origin. All of these men were present except Mr. Enslow, who, although unable to come to Mobile at that time, kept in close touch with the progress of the operation of the plant.

Feature of Filtration Plant.—In designing the new filtration plant, one of the two basins formerly used for plain sedimentation was converted into the coagulating basin, part of one end of which was divided into seven rectangular mixing chambers 4 ft. square and 10 ft. deep, connected at the bottom by 12 in. 90° ells with 18 in. nipples, giving an upward velocity to the water as it enters each successive chamber. The total retention period in the mixing chamber is 12 minutes. The total capacity of the coagulating basin is approximately 500,000 gal. The iron sulphate, sodium aluminate, and lime used in treating the water are fed through Wallace and Tiernan dry feed machines and the chlorine is fed through a Wallace and Tiernan Type MSV chlorinator. In order to obtain complete oxidation of the ferrous sulphate, a lard barrel was used for the introduction of both the sulphate and chlorine in such a way as to cause a churning and swirling action, the resultant mixture from this barrel passing to the first mixing chamber where the raw water is introduced. The spot test, using the potassium ferricyanide, was used as a control at frequent intervals throughout the period of operation. Water was pumped at the rate of 700 gal. per minute from the coagulating basin to the filters which consist of two rectangular units each having a capacity of one half million gallons per 24 hours.

Operation of Plant.—The plant was operated both continuously and intermittently. When operated intermittently, the period of operation was 10 hours and remained idle 14 hours. Coagulation was obtained by the use of "chlorinated-copperas" alone and also in conjunction with sodium aluminate. When sodium aluminate was used, it was introduced into the third chamber of the mixing chambers after a theoretical detention of 4 minutes in contact with the copperas. A good floc had already appeared in the second chamber from the use of "chlorinated-copperas" alone. Good coagulation was obtained by using .7 grains per gallon of iron sulphate and .126 grains per gallon of chloride. Although this quantity of chlorine gave excess of 2 parts per million at the end of the mixing chamber, all residual chlorine had disappeared before the water had reached the end of the last day of the coagulation basin. Sodium aluminate, when used, was introduced at the rate of .4 grains per gallon.

Provision had been made for introducing lime at various points in the last bay of the coagulating basin and also into the clear water well. At different times the lime was introduced at a point about 50 ft. from the coagulating water pump, 130 ft. from the coagulating water pump, and into the clear water well immediately adjacent to the filter effluent pipes. When introduced into the coagulating basin, the effluent was not as satisfactory as the final treated water was found to be after the introduction of lime into the clear water well. Although there was a very slight increase in color when the lime was introduced into the clear water well, the color was not as great as the filter effluent was when lime was introduced into the coagulating basin. In all cases, lime sufficient to adjust the pH up to 7.0 or 7.2 was used. The alkalinity was raised to 7 or 8 parts per million. The final color was probably not more than 3. This, however, is an estimated figure, as the lowest disc of the U. S. G. S. color standards which we had was for a color reading of 7. When "chlorinated-copperas" was used alone, for the floc obtained was apparently lighter and was carried in comparatively large quantities a greater distance through

the coagulating basin than was the floc obtained when sodium aluminate was added as described above. However, it was noted that the floc when sodium aluminate was used, was more agglomerated and, although a heavy deposition occurred in the first third of the first bay of the coagulating basin, the remaining floc seemed to have a less specific gravity than that resulting from the use of "chlorinated-copperas" alone. The final treated water obtained, when sodium aluminate was used, was only very slightly different from that obtained when "chlorinated-copperas alone was used for coagulation. No difference could be detected by the ordinary laboratory tests. When viewed through a 10 ft. depth in the clear water well, the opinions of five observers differed as to which effluent was the better or whether there was any perceptible difference whatever. It will thus be seen that the difference in results in the particular water being handled during these experiments would make the additional cost of sodium aluminate questionable — this cost alone being greater than that of all three other chemicals combined.

It must be remembered that this is an absolutely new filtration plant, that the sand has not ripened, and that the period of operation has not been sufficient to demonstrate conclusively what might be expected under the varying conditions of water which will be found through a twelve months' period. However, although these results are not final, we are convinced that this method is practical, economical, and efficient under conditions similar to those now existing. The efficacy, when water of a different quality must be treated, can be determined only after further observation.

State Supreme Court Uphold Ohio Sanitary District Law

In a decision handed down March 27, in a case on appeal from the Mahoning county courts, the Ohio Supreme Court affirmed the constitutionality of the sanitary district law, which had been attacked by two citizens of the Mahoning Valley Sanitary District as taxpayers, on the alleged ground that the legislature could not delegate power and authority to levy taxes to an appointive body. Commissioners of the sanitary district are appointed, instead of being elected. Plaintiffs lost in the Mahoning County Common Pleas Court, and appealed on error to the Court of Appeals, which affirmed the decision, and appeal to the Supreme Court followed. This decision removes the last existing legal barrier to progress of the sanitation work designed to furnish pure water to the cities of Youngstown and Niles.

Automatic Devices in Filter Plant

Care and Adjustment of Controller Gauges and Other Mechanical Equipment

By RICHARD F. WAGNER
Director of Safety and Water, Lynchburg, Va.

The city of Lynchburg was very fortunate when securing its purification plant in that the parties charged with its design appreciated the value and importance of certain automatic devices and spared no efforts or expense to secure them.

Automatic Devices.—The more important automatic devices were the following:

1. One 24 in. venturi rate controller, with a register-indicator-recorder and special electrical transmitting device, for operating the chemical feed controllers.

2. Three chemical feed controllers automatically operated electrically from the register-indicator-recorder.

3. Twelve 6 in. self-contained filter rate controllers, one 6 in. wash-water rate controller, and one 12 in. wash-water rate controller, with 14 special rate of flow indicators.

These controllers, consist essentially of a venturi tube, with hydraulic gate valves in the down-stream cone. The movement of the gate valve is controlled automatically so as to maintain a constant rate of flow regardless of pressure variations. The method used in the utilization of the difference of pressure from the venturi tube applied to a diaphragm which in turn operates a pilot valve which controls the movement of the hydraulic gate. The setting of the rate at which the controller operates is accomplished by moving a weight on a graduated scale beam.

A check of the proper working of the controllers is secured by the rate of flow indicators, which consist of a glass tube projecting into a well of mercury with the necessary connection of the meter tube, the difference in pressure causing the mercury to fluctuate in the glass tube.

Care of Packing.—The cylinders of our hydraulic gate valves are brass, so are the gate girders. After a few months' operation of the plant, some of the controllers became sluggish and in some instances it became necessary to remove the caps of the cylinders of hydraulic gates for the purpose of renewing or replacing packing around plunger. This packing, of course, hardens under use and it has been our practice to hammer it back to life after washing it thoroughly in a strong solution of soda ash. We then coat it thoroughly with a mixture of extra light petroleum jelly and flake graphite. It is of a good deal of importance to replace or renew packing in such a manner as to prevent a displacement of gate stem. This we have accomplished by measuring the distance of stems from cylinder walls in four directions before removing packing, taking care that such measurements are accurately secured upon the completion of the repair job.

We have also found that the insertion of a set screw in gate girder stem will prevent too tight a shut down; the screw being set in such a position as to present a complete seat.

We have experienced little if any trouble with diaphragm boxes, taking the precaution, however, of removing tops at certain intervals and cleaning boxes thoroughly.

Our pressure gauges, recording and otherwise, are checked from time to time by a gauge tester, a device every water plant should possess. This tester works by series of weights with glycerine as the fluid used.

Chemical Feed Controllers.—While our chemical feed controllers were designed to work automatically by an electrical device geared to our venturi meter, we found this method impracticable, we, therefore, calibrate the flow from orifice boxes manually once an hour, a program clock calling the attention of the operator on duty to this task. This method has been eminently satisfactory, chemicals consumed being checked once daily against the rate of application. All the attention the chemical feed devices require is a complete cleansing at certain intervals.

Care of Chemical Pumps.—Chemical pumps of the piston type, especially such pumping alum solutions require frequent grinding of valves, which we accomplish identically in the same manner an automobile mechanic grinds the valves of your car, very little practice will soon make your operator an adept in this game.

Though we use chlorine but seldom, we possess three units to apply such gas. We subject these to periodical tests, sometimes with gas, then again with air. One thing of importance, of course, to prevent corrosion and assume long life of this apparatus is to prevent leaks, even the smallest; doing so requires painstaking, thorough attention of the operating personnel.

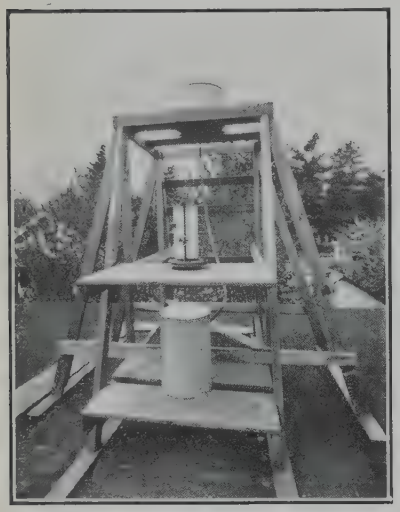
Any plant designed and constructed in accordance with the latest methods will not function properly unless the person in charge of operation is intelligent and has the proper sense of responsibility. This person will soon sense the fact that automatic devices, gauges and other equipment are valuable assistants and will treat them accordingly. He will insist that his personnel also become acquainted with them thoroughly, from the inside out, and that a deal of elbow-grease be applied in keeping them clean and certain surfaces sparkling.

Acknowledgment.—The foregoing is a paper presented at the first Virginia Conference on Water Purification and Sewage Treatment, held April 25 and 26 at Richmond, Va.

Recent Developments in the Water Works Field

A Simple Recording Rain Gage

Leupold, Volpel & Co., Portland, Ore., have recently adapted the Stevens Type L water level recorder to the recording of rainfall. A collecting tank is mounted on a suitable platform and is connected by flexible rubber hose to a float tank. The recording instrument is



Recording Rain Gauge Mounted on the Roof of a Building

placed over the float tank and records the elevation of the water in the tank. The collecting tank and the float tank are so proportioned that any desired magnification of record can be secured. In the bottom of the float tank is a stop cock by which it may be emptied at the time the clock of the recorder is wound.

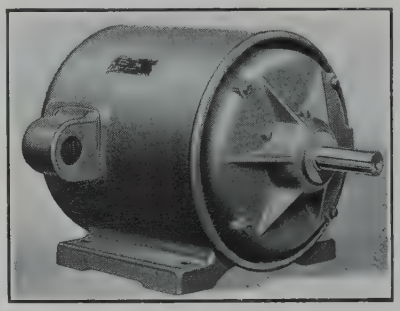
The graph made by the recorder is a mass graph of rainfall by means of which the total amount and its intensity may be readily determined. The illustration shows the recording rain gage mounted on the roof of a building. The collecting tank area is 2.4 times the float tank area. The chart on the recorder is graduated in hundredths of feet with each tenth line accented. Each tenth of a foot therefore on the chart corresponds to a half inch of rainfall, the record being magnified to 2.4 times. Any other scale of magnification can be secured. The instrument shown is a weekly recorder giving a space of about 2¼ in. per day. In cases of heavy rainfalls with great intensities, the same recorder is used, but a daily or a 12-hour chart is substituted and the clock is geared so that the drum makes one revolution in one day or 12 hours. When there is no rain the pencil makes a continuous line, but whenever railfall occurs a record of the amount and intensity is assured to a time scale that will be legible. The daily chart corresponds to a scale of 18 in. per day, with the smallest division of time representing 10 minutes. In the case of the 12-hour chart, the day space is 36 in. and the smallest division represents 5 minutes.

For isolated localities that cannot be visited once a week, a recorder is used that will run one or two months with one setting. In such cases a float tank is provided that is deep enough to hold any amount of rain that might occur during such a period.

During the dry periods following a rain the graph will show a slight decline due to evaporation from the tank. This however is of no consequence, because whenever a rainfall occurs the total amount and the intensity can readily be determined above the point shown by the graph at the beginning of the rain.

New Motors Developed by The Louis Allis Co.

Experience of 1928 assisted The Louis Allis Co. of Milwaukee, Wis., in developing enclosed motors of reasonable size. These are the explosion-proof, self-ventilated motor for use in explosive atmospheres; and the enclosed self-



Louis Allis Enclosed Self-Ventilated Motor

ventilated motor for applications involving less hazard but requiring a fully enclosed motor. These developments, together with our Resistallis protective coating for the windings of open motors, fill industry's need for motors of reasonable size suitable for applications involving various degrees of hazard either to the motor winding or the surroundings. To machinery manufacturers the outstanding advantages of these three types of protected or enclosed motors are that they are small enough for mounting direct on the driven machine. These motors enable the manufacturers to adapt standard machines, built to accommodate standard motors, to hazardous and semi-hazardous industries. The features of the three types are noted briefly below.

The explosion-proof motor is fully enclosed and self ventilated. It has been tested and listed by Underwriters' Laboratories for use wherever gasoline, or liquids of equivalent or less hazard such as other petroleum products, ethyl alcohol, methyl alcohol, and acetone, are made, used, or handled. When direct connected to machines in explosive atmospheres, thus eliminating belts, this motor eliminates the serious hazard of fire from sparks due to belt static. It is only slightly heavier than an open motor of same capacity, can be installed in same space and is interchangeable in mounting dimensions.

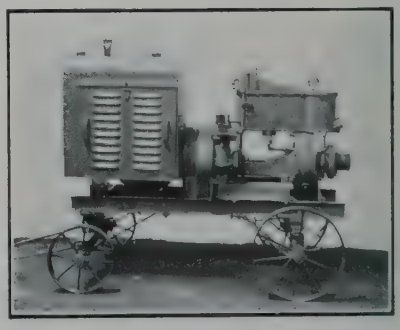
The enclosed self-ventilated motor is fully enclosed and sealed against excessive dust, moisture, oil, acid, alkali, fumes, and other foreign matter. It is cooled by the surrounding air forced through the outer shell over the surface of the enclosed motor frame. Clean air is not required. There are no pipe connections or air ducts. It is only slightly heavier than an open motor, installed in same space, and is interchangeable in mounting dimensions.

Resistallis coating protects windings of open motors and makes them suitable for installations where considerable quantities of organic dust, iron dust, moisture, acid, or alkali are present. Resistallis entirely covers coil ends and slots, is not affected by temperature and does not affect ventilation. It makes a standard motor suitable for reasonably severe duty without added cost.

Self-Priming Portable Centrifugal Pump Announced

One of the latest features of the Domestic Engine and Pump Company's line of water works equipment and one of their most popular units is a self-priming centrifugal pump. Their factory is located at Shippenburg, Pa.

With this automatic primer attached to any of our standard centrifugal pumps it is only necessary to submerge the end of the suction line in water and start the engine. It is not necessary to put water in any part of the pump,



Domestic Automatic Priming Centrifugal Pump

suction line or primer. With a tight suction line it is possible to create a 27 in. vacuum which is equivalent to a 30 ft. suction lift. This primer has been tried out over a period of several years and has proven very successful.

Another new unit is their 1929 Model 164 open spout diaphragm pump with force attachment. They have increased the practical range of diaphragm pump uses by manufacturing an attachment whereby the Domestic open spout diaphragm pump can be converted into a force pump, for temporary use, in a short length of time and with the aid of only one tool, a monkey wrench. They have, in manufacturing this attachment, given the user of such type of pumping equipment something that has been very much needed for some time. It often happens that when using a diaphragm pump the need arises to temporarily force the water away from the scene of action and with this attachment the process is simplified greatly.

Oxweld High Strength Welding Rod

An improved bronze welding rod, designated Oxweld No. 21 high strength bronze welding rod, has been placed on the market by Oxweld Acetylene Company, 30 East 42nd Street, New York City. This rod is recommended for all bronze welding applications including the fusion welding of brass and bronze, bronze-welding of malleable and gray iron castings, joining dissimilar metals and building up bearings

Bronze-Welded 6-in. Galvanized Water Line

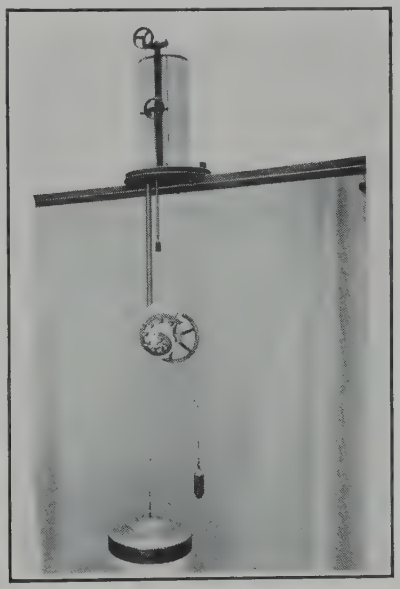
and other wearing surfaces. Due to its composition it has a uniformly low melting point and easily controlled flow. It produces a weld metal as hard and wear resistant as that formerly made with manganese-bronze rod. By its use, tough and ductile weld metal having a tensile strength of over 45,000 lb. per sq. in. can be produced. This is about 15,000 lb. per sq. in. in excess of the strength obtainable with earlier bronze welding rods. In addition, it will make a much stronger bond with ferrous metals.

Properties of this rod eliminate almost all boiling and fuming of the weld metal. Annoying fumes are reduced to a minimum and elimination of oxide and gas inclusions is a reason for both the remarkably sound and strong weld metal produced and the better adhesion to iron and steel.

Oxweld No. 21 high strength bronze welding rod has been thoroughly tested in the laboratory and in the field. It is believed that it will greatly widen the already broad scope of the most versatile of all the oxy-acetylene operations, bronze-welding.

A New Flow Recorder

The illustration shows a device recently perfected by Leupold, Volpel & Co., Portland, Ore., manufacturers of Stevens water level recorders and indicators, whereby the flow in second-feet, gallons per minute, liters per second, or



A New Flow Recorder

any other unit may be recorded on a chart to a uniform scale.

Attached to the base of the instrument is a float pulley which actuates an adjustable spiral cam, which in turn actuates the recording pencil on the recorder. For weirs, sewers, flumes or ditches, where the rating is known or for any device where the height of water is an index of flow the cam may be adjusted so that the pencil will record the flow in any desired units. The spiral is a strip of rubber in which a groove has been milled that is held by clamps. If the rating of a device is known, the rubber cam is clamped in such a position that at all points the pencil will show the correct flow corresponding to these heights.

The instrument may also be provided with Stevens volume meter, which is a totalizing device by means of which the total volume passing in gallons, acre-feet, or any other unit or quantity is registered on dials.

When required, an additional pencil is provided that will record head at the same time, so that this simple device may be used to record head of water, flow, and total volume.

Quinn Develops New Machine

An improved Quinn machine for the manufacture of concrete pipe in sizes 18 in. to 60 in. in diameter and lengths

Quinn Improved Pipe Machine

of 4, 5 and 6 ft., tongue and groove pipe ends. The Quinn Wire & Iron Works of Boone, Ia., are the manufacturers.

This machine has a capacity of from 75 to 100 tons per day depending on the size of pipe being made. It makes either plain or reinforced pipe, single or double reinforcing. The tamping mechanism on this machine strikes a very powerful blow, in fact when the jackets are removed from the concrete which is done immediately after the pipe is made, the material is so dense and hard that it is almost impossible to dent same by applying pressure to the outside or inside.

The improved Quinn machine has the advantages over other processes of making concrete pipe in that it not only makes a pipe economically, but it produces a pipe of the very highest strength, owing to the fact that it uses a semi-dry mix with very little slump and just enough water to hydrate the cement and by applying the terrific trip hammer blow of from 600 to 700 lb. each blow. Operating 370 times per minute, the hammering effect produces a very dense, hard and compact material as it is forced into the forms. This process develops a very high strength in the concrete, eliminates all air pockets and forces the material together in a dense mass. This also gives a very low absorption.

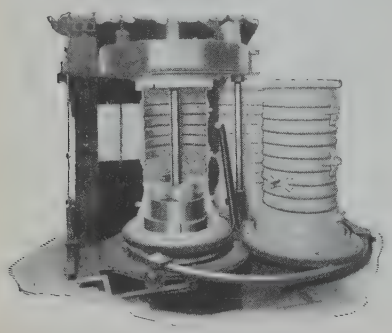
It has been demonstrated from various tests made of Quinn pipe in the larger sizes that the first crack test exceeds all other processes on the market today. Purchasers of pipe and engineers in charge are realizing more and more the importance of high strength in their concrete for sewer work and to this end are recognizing the first crack test as being the most important.

Longer Concrete Pipe Manufactured

Engineers, officials and contractors who specify, approve and use sewer pipe, will be interested in the announcement that McCracken corrugated concrete pipe are now made in three-foot lengths instead of thirty-inch lengths as was formerly the case.

McCracken concrete pipe are made in a number of strategically located local plants. These plants operate concrete pipe machines, manufactured by the McCracken Pipe and Machinery Corporation, Sioux City, Iowa. The company announces a second improvement in concrete pipe manufacture which increases the daily output of each plant and results in a definite improvement in the product.

The McCracken machine automatically manufactures sewer pipe from six



Showing McCracken Wall Packer at Bottom of Its Stroke

to twenty-four inches in diameter, three feet long. Each pipe is made in a steel jacket which is released from the green pipe immediately the product has been wheeled to the curing room.

In every McCracken pipe plant a conveyor line keeps the mixer supplied with raw dry materials and the mixed concrete is discharged into the elevator boot of the pipe-making machine. From that point to the completion of the manufacturing cycle, the operation is automatic. The elevator lifts the mixed concrete above the mold, which stands on a revolving table, depositing it in a circular batch hopper just above the mold.

Hence the concrete feeds automatically into the mold when the revolving wall packed reaches the bottom of its downward stroke. At this point the auxilliary bell packing head is at its top position making the bell or socket of the pipe. This requires from five to seven seconds. At the same time the wall packer on the main vertical shaft is packing the shoulder above the socket. Then the two packers draw apart—the bell packer moving out of the finished socket and the wall packer rising through the pipe packing the wall as it rises.

Until quite recently as much time was consumed in sending the wall packer down through the mold, which is an unproductive trip, as was consumed in bringing it up through the mold during its packing operation. Thus 50 per cent of the time of the wall packer was unproductive. An improvement of the machine has resulted in cutting the unproductive time of this unit down to 20 per cent. In other words, it travels on its downward trip much faster than it travels on its upward trip. This not only speeds production but results in a definite gain in quality.

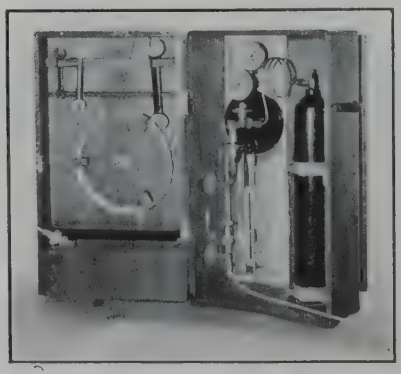
A New Portable Chlorinator

The Paradon Manufacturing Company, Arlington, N. J., have developed a portable chlorinator which can be moved about from place to place as conditions require.

The apparatus consists of a standard Paradon dry feed chlorinator housed by means of brackets in a sturdy oak cabinet. This cabinet is self-supporting. The cabinet is provided with a door on both front and rear. The gauges and control handles of the chlorinator are so arranged as to be accessible from either the front or rear door. The front door is constructed so that the wrenches and other auxiliary equipment supplied with the chlorinator can be stored loosely in the recesses provided. A 12 lb. cylinder of chlorine is attached within the cabinet by adjustable clamps.

All of the parts of the apparatus are interchangeable with the parts on the standard Paradon Chlorinator. This insures prompt service in connection with replenishment of parts. The equipment can at any time be removed and set up on a pedestal and it then becomes a standard permanent chlorinator.

The chlorinator is of the direct feed type. No auxiliary water supply or piping is necessary for its operation. Chlorine can be applied against pressures up to 25 lb. per sq. in. without any additional equipment. Capacities range from .04 lb. to 3 lb. per 24 hours, from 1 lb. to 5 lb., from 5 lb. to 25 lb. and from 25 lb. to 125 lb. The apparatus can be provided with all four ranges, if desired. Any desired capacity from 125 lb. to 300 lb. chlorine per 24 hours can be supplied if required.



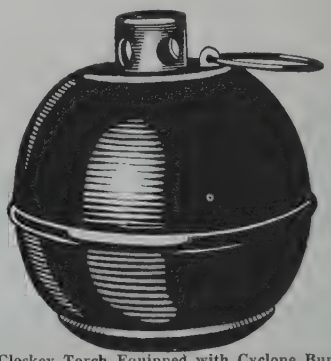
Paradon New Portable Chlorinator

The apparatus is provided with a shut-off valve which enables chlorine gas to be kept in the machine at all times under pressure, thus eliminating the possibility of water or moisture getting back into the apparatus and affecting its proper operation.

The uses of the portable chlorinator are many. It is a convenient device to have around a water works plant. One very useful purpose it serves is to provide means for sterilizing mains at all times. After a main is constructed and before it is put into use it can be effectively sterilized by means of this device. Dead end mains, showing signs of after contamination, can likewise be sterilized. The portable chlorinator can be used as a standby for the regular chlorinator. It can be used for prechlorination, algae control, odor control, color control, coagulation control. It can also be used for the application of sulphur dioxide in dechlorination, for carbon dioxide, and so forth. This unit was originally developed for the Water Department of the City of Syracuse where one has been in service with success for several months.

McCloskey Announces Torch Attachment

The McCloskey Torch Company, of Toledo, Ohio, announce their new Cyclone burner. The torches which are not equipped with this burner can



McCloskey Torch Equipped with Cyclone Burner

readily be converted by using an adapter for the purpose.

McCloskey torches are made in two halves, of rolled and pickled deep drawn steel and welded together. Sufficient cast iron counter balance pressed in the bottom absolutely prevents them from being knocked over.

The No. 1 large size torch, the manufacturer states, is made of 13 gauge metal, holds a quart of kerosene, and burns for 48 hours. The No. 3 size is 15 gauge metal, holds 3 quarts and burns 36 hours.

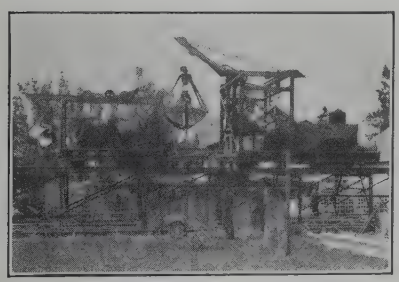
Further information may be obtained from McCloskey Torch Co., Toledo, Ohio.

Potter Improved Trench Excavator

The new Potter trench excavator handles a wide range of work and has built sewers of pre-cast construction from a diameter of 2 ft. to 8 ft. and in depths from 8 ft. to 35 ft. and widths up to 14 ft. The standard length of the trestle is 200 ft.

This machine is manufactured by the Potter Manufacturing Co. of Indianapolis, Ind.

Two standard double drum Lidgerwood gasoline hoisting engines are used for power, the one on the derrick car is a Buda 50 hp. engine and the



Potter Trench Excavator and Conveyor

one on the conveying car a Buda 30 hp. The clam shell is a ¾ yd., narrow type, heavy duty Owen bucket.

The whole machine can be moved ahead at will on railroad rails as each bent leg has a double flange wheel that runs on the rail. The bents are spaced 10 ft. apart and the track gage at the bottom is 10 ft. 4 in. and the track gage on top is 10 ft. 4 in.

The conveying car is a combination hoist and conveying car and receives the excavation from the clam shell and conveys the excavation back and dumps it on the completed work, while the clam shell is going down after another bite, thus doing double work.

The hoist feature lowers pipe into the ditch and does general hoisting work, such as pulling sheeting and bracing timbers out of the trench.

A vast amount of work can be accomplished with this machine and the use of it makes a clean organized job, all operations being carried on simultaneously, the excavating, sheeting, pipe laying and back filling. It is not necessary to pile the excavation on the abutting property owner's front yard or property. The machine handles work in narrow alleys, up city streets or out in the open. It permits the operation of street car and vehicular traffic in city streets where the sewer is on one side of the street.

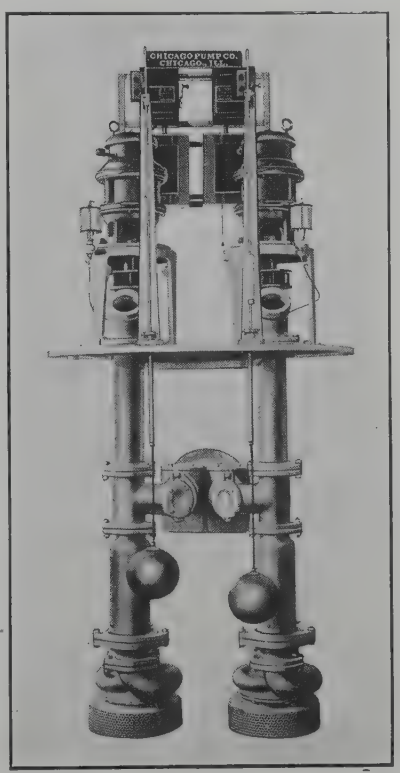
It requires two operators for the machine, which are at all times directly over their work. The operator on the derrick car can spot his bucket in the ditch with great accuracy and can move from one digging section to another with practically no loss of time and can handle as many digging sections or steps in the ditch as is necessary, according to the depth and the type of sewer required. The conveying car operator can spot the back fill in a most advantageous way, to extract the sheeting and bracing in the most economical manner. This enables the operation to become speedy and efficient.

The machine has surpassed the expectations of each sewer contractor that has used it, and has completed work far ahead of schedules laid out, the manufacturer claims. It has been used on small contracts and one up to $2,000,000. This machine has been very much in favor with city officials, on account of the fact that the sewer work can be handled with great speed and permits traffic to be kept open on main thoroughfares and makes for a neat, clean job, eliminating the piling of excavation on the side of the trench, or on abutting property, which invariably causes a lot of dissatisfaction where that is the practice.

Improved Sewage Ejector

The Chicago Pump Company, Chicago, Ill., calls attention to the following items which were recently brought out and have a use in the water works field.

First in importance is the Flush-Kleen sewage ejector. The important point about the Flush-Kleen sewage ejector is that it will discharge large and heavy materials. The submerged Flush-Kleen will pump successfully into the sewer, any sewage or foreign material which can run into a basin from sanitary lines. The Flush-Kleen sewage ejector has a self cleaning screen and rags, sticks and paper cannot clog the impeller because they do not come in contact with it. It is controlled by the Automatic Alternator which causes pumps to alternate their operation. First one pump takes up the work and then the second pump goes into operation while the first pump is at rest.



Flush-Kleen Sewage Ejector

A bulletin issued by the Chicago Pump Company goes into detail on all these points.

Second in importance to the water works field is the Non-Clog sewage ejector.

The Non-Clog like the Flush-Kleen, does not need a screen. It will pump heavy cumbersome materials and will pass wooden balls as large as 3⅝ in. in diameter. It will be observed that Non-Clog impeller will discharge any substance or objects which can pass into it.

The Non-Clogs are particularly adapted for lift stations in the smaller towns and municipalities.

The impeller has but two blades with carefully rounded edges. All water ways are smooth. There are no projections on which rags, strings or other material can catch.

It is keyed to the shaft and is held in place against shoulder on the shaft by a brass locknut.

High efficiencies are obtained over a wide range of capacities and heads due to very careful design and experience in pump building.

The Little Giant electric cellar drainer can be used to advantage in bilge and sump work where medium quantities of water are to be handled.

H-Section Fence Posts Announced

The Cyclone Fence Co., of Waukegan, Ill., announces the introduction of H-section posts for use with Chain Link fence guard.

In the past, fence builders have been dependent upon the use of standard shapes for posts and the fence built to adapt itself to the available shapes. The H column post is the first shape which has been designed particularly for use with Cyclone Chain Link fencing to insure maximum strength. A liberal margin of safety has been allowed in designing this post for the particular service which it must perform.

Its analysis, its measurements and its appearance have been agreed upon by both fence and steel research engineers after experiments carried on over a period of several years.

It is galvanized in Cyclone factories by the Cyclone Galv-After process and each post is embossed with the word Cyclone at four foot intervals.

It has a copper content of approximately .20 per cent.

C. H. & E. Sewage, Trash, Triplex Lift and Force Pumps

The C. H. & E. Manufacturing Co., Inc., Milwaukee, Wis., is now manufacturing a line of five sizes of sewage and trash pumps, powered by four cylinder engines from 15 to 45 h. p. through flexible coupling, with capacities from 400 gallons per minute at 50 ft. total head, to 2500 gallons per minute at 35 ft. total head.

These pumps are for the economical handling of fluids containing large solids and much foreign matter, particularly material of fibrous or stringy character such as is found in sewage. These pumps have two very definite advantages which greatly influence the efficiency and economy of operation; first, continuity of performance, without clogging; second, the elimination of the necessity and expense of screening out solid material in the fluids to be handled.

The impeller will pass anything that enters the suction nozzle, the pump being designed to handle solid spheres as large in diameter as the pipe size next smaller than that with which the suction connections to the pump are made.

In construction and drainage service they are used to great advantage where the water to be pumped contains rubbish, roots, sod, weeds or other objects which clog ordinary centrifugal pumps that have been tried unsuccessfully for trash pumping service.

These outfits are mounted on steel skids or steel trucks. Priming pump, clutch and all discharge fittings are standard equipment.

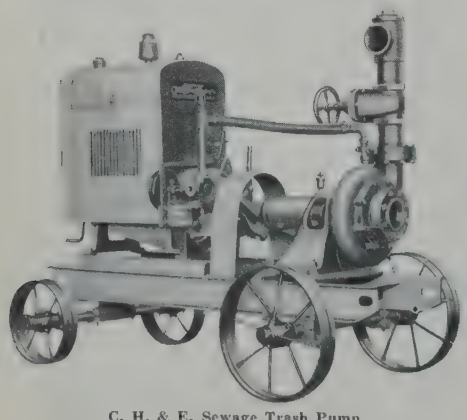
A new Triplex lift and force pump has been developed by the C. H. & E. Manufacturing Co., Inc., of Milwaukee, Wis.

This is a very sturdy, dependable outfit, designed to handle water carrying a large percentage of solid matter, and to force the water away from the job.

The outstanding features of this Triplex lift and force pump are a high suction lift, and self-priming, which eliminates constant attention.

Large metal valves are used, and there are large openings in the valve seats to allow solid matter to pass through. The suction and discharge valve cases and the water box are designed to allow the water to flow freely. The valves are very accessible, each valve having an individual cover held down by a clamp. The clamp is slotted on one end, which only necessitates the loosening of one nut a few turns to remove the clamp and valve cover.

This pump has machined cross-head guides which are lubricated from the plungers. Packing is not used as a quide for the plungers. The plungers are outside packed and easily accessible. Connecting rods are of the eccentric type, lubricated by individual sight feed oilers. The pump is driven by two machine cut gears of wide face. It will develop a 25-in. vacuum, and handle up to 100 well points, it is claimed, depending on the size of the points used and soil conditions.



C. H. & E. Sewage Trash Pump

Byers Announces New Process for Wrought Iron

The culmination of ten years' research work in the metallurgical field is reflected in the announcement of the A. M. Byers Company of Birmingham, Ala., at the American Water Works Association Convention of their new process for the manufacturing "Genuine Wrought Iron."

Briefly, the new process reproduces the same reactions that took place in the hand-puddling furnace, but with greater uniformity. Tests by leading metallurgists from Great Britain, Germany, and the leading railroads and petroleum interests of this country, indicate an iron with almost perfect slag distribution.

Pipe manufactured from the new material welds better, fabricates more easily and contains possibilities of being ultimately manufactured on a scale comparable with that of steel.

In the Byers new process, the definition of wrought iron, the temperatures and the chemical reactions which took place in the older processes have served as guides in working out several independent but definitely related steps. Above all, the principle is kept in mind for a composite material consisting of a refined base metal and slag. These two elements are therefore first produced separately and then mixed in such a manner as to produce a spongy ball which in all particulars, except in size, is identical with that obtained in a hand-puddling furnace.

The base metal refined may be carried out in slightly modified Bessemer, open hearth or electric furnaces. The pig iron is refined to an exceedingly low metalloid content, particularly with respect to carbon, silicon and manganese.

Slag is melted in standard types of furnaces from readily available raw materials, chiefly iron ore, roll scale and sand. The molten slag is an iron silicate conforming to the composition and characteristics of slag formed in the best hand-puddling practice.

The crux of the Byers new process lies in the so-called "shotting" operation. This operation consists in pouring the liquid metal which, as is well known, carries large amounts of gases in solution into a bath of molten slag. When the molten iron at a high temperature strikes the molten slag at a slightly lower temperature, there is, due to the sudden drop in temperature, almost instant solidification of the metal, and the gases are expelled with such a force that there are a million tiny explosions which have the effect of instantly disintegrating the metal as perfectly and uniformly as it may be observed to take place, though at a much lower, slower rate in a hand-puddling furnace.

The semi-solid globules of metal, owing to their high specific gravity, settle to the bottom of the slag bath, forming a spongy, porous mass of exactly the same composition as a puddle ball. In the heat interchange, hot metal naturally raises the temperature of the slag so that it remains liquid, thoroughly coating each globule as fast as it forms, and filling the interstices of the entire metallic mass.

From this point on, no change in the manufacture of the iron is made, except that the equipment is much larger and much heavier, due to the fact that the puddle ball is ten or more times larger than that produced in the former hand-puddling process.

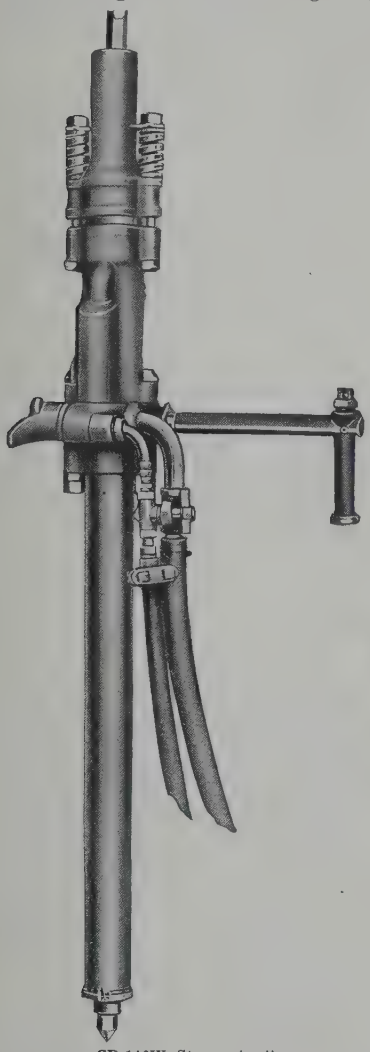
Sweet Designs Fence Post

Sweet's Steel Co. of Williamsport, Pa., announce production of steel posts of flanged leg channel section. The posts have been designed from the results of research. The tests conducted were interpreted by the company in such a way that they eliminate ground plates.

Their posts are equipped with rivet lugs for holding fence or wires where desired. This method, the manufacturer states, of attaching fence to posts is exclusively a Sweet's feature. They state that by the rivet lug method the shearing of fence wire is reduced to a minimum.

Hand-Rotated Stopers

The Chicago Pneumatic Tool Co. of New York, have perfected their stopers and state that the CP-146W stoper (wet) combines high drilling speed, light weight, short overall length, ease of operation, low upkeep and effective and convenient air feed control for difficult drilling conditions. Being fully



CP-146W Stoper (wet)

cushioned and valve actuated, it does satisfactory work under poor conditions such as low air pressure, wet air and the added handicap of worn parts.

The main features incorporated in this drill can be summarized as:

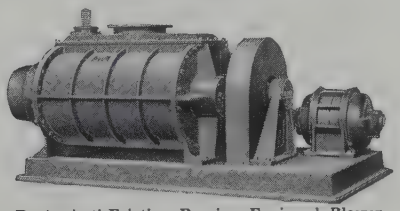
(1) Symmetrical balanced design—easy to operate.
(2) High drilling speed over a wide range of formations and conditions.
(3) Light weights.
(4) Four-bolt construction—gives ready accessibility to all working parts.
(5) Spring-retained front head.
(6) Fully cushioned, one-diameter piston—insures long life.
(7) Rugged, tubular valve, housed in renewable bushings in the cylinder wall, and piston-controlled exhaust—absolutely no tendency to "freeze" under the worst conditions.
(8) Effective, air-operated feed control, conveniently located in the rotation handle.
(9) Full 24-in. feed travel—facilitates steel changes.
(10) Air and water swivel connections conveniently located.
(11) Automatic lubrication.

Roots Blowers Now Use Anti-Friction Bearings

The P. H. & F. M. Roots Company, Connersville, Ind., originators, patentees and manufacturers of two-impeller rotary positive displacement units, announce the general adoption of anti-friction bearings for their blowers and Acme blowers.

The standard line of blowers carries Timken or SKF heavy duty roller bearings upon the purchasers' specification, and the Acme line of smaller units carries roller or ball bearings upon specification.

Constant research and construction work over a period of the past twenty years has convinced The P. H. & F. M.



Roots Anti-Friction Bearing Equipped Blower

Roots Company, established 1859, that the manufacture of anti-friction bearings has now been perfected to the point where they recommend and use them.

A roller bearing has not merely been substituted for one of the adjustable babbitted type. The Roots Blower construction has been re-designed entirely, and changed to allow every additional operating advantage. Extreme care has been taken in designing the mounting. Complete protection from the entrance of foreign substances into the bearing housing has been afforded. Ample space is allowed around the bearing for a sufficient supply of lubricant, and provision is made for forcing the lubricant through the bearing from one side to the other.

In no case does the maximum load and speed of the bearing selected exceed one-third of the manufacturer's rating. Aside from the reduction in friction loss, Roots blowers with anti-friction bearings offer new possibilities for direct connection to smaller motors with less horsepower to obtain increased capacities, operate with higher efficiency by permitting the use of more closely fitting cases, permit greater capacities with conservative speeds, and deliver more volume with less horsepower.

Before the adoption of anti-friction bearings, The P. H. & F. M. Roots Company had listed 141 different applications of their products throughout all industry, and the change to the roller and ball constructions opens even a wider field for the use of rotary positive displacement blowers thus equipped.

Link-Belt Announces a Complete Line of Gasoline Locomotive Cranes

Even locomotive cranes are now driven by gasoline engines. Link-Belt Company, Chicago, Ill., has announced a complete line of locomotive cranes designed especially for gasoline engine, Diesel engine or electric motor drive, to be known as the L type cranes.

They are not merely modified steam cranes, but are designed throughout for the entirely different and much more severe conditions imposed by a power unit running continuously at its full operating speed.

The machinery and its arrangement are particularly adapted to direct engine or motor drive, and all clutches, brakes, shafts, bearings, gears, etc., are oversize in order to give the best operating results and the lowest possible maintenance expense, under these conditions.

The drive from engine or motor is a totally-enclosed silent chain drive, and all upper frame gears have machine cut teeth, cut from solid blanks. This makes a quiet, smooth operating machine.

It is furnished with two-speed travel gear to give a high travel speed for traveling light, and a slower travel

Link-Belt Locomotive Crane

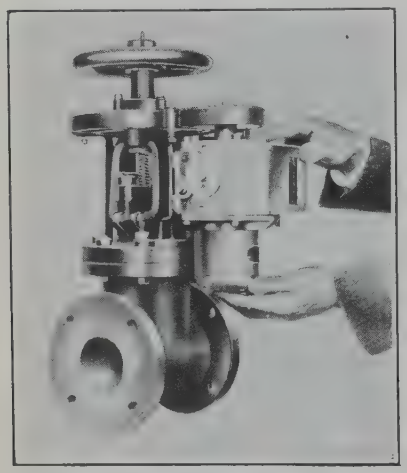
speed for pulling heavy loads or ascending comparatively steep grades. The two-speed travel gear in no wise affects the other speeds of the machine (hoisting, boom hoisting and rotating), which should, under all conditions, remain unchanged in order not to affect the operating speed and handling capacity of the machine.

The addition of the L-type crane in five sizes gives Link-Belt Company a complete line of gasoline, diesel, electric and steam locomotive cranes, and a line of heavy duty gasoline, diesel, or electric crawler shovels, cranes and draglines ranging from ¾ cu. yd. to 2 cu. yd. capacity.

New Motor Driven Mechanism for Operating Valves

A new motor driven valve operating unit has just been announced by The Cutler Hammer Mfg. Co., Milwaukee, Wis., which makes possible automatic operation of all valves up to 6 in.

Although so small that it can be held in one hand, this unique operating unit



Cutler-Hammer Motor Driven Valve Operating Mechanism

has a rating of 15 ft. lb. It can be operated automatically by means of float switches, temperature controlling devices, pressure regulators, etc., or by conveniently located push buttons.

Although only recently placed on the market this valve operating unit is similar in principal to the standard C-H Dean operating unit which has a successful record of 12 years.

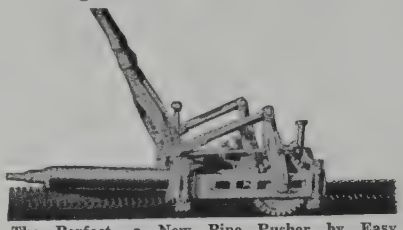
While designed primarily for valve operating service in industries where regulation of pressures and temperatures of gases and fluids is necessary, it is likewise adaptable to many miscellaneous applications, such as operating skylights, awnings, radiators, garage doors, etc.

Literature describing this new unit (called C-H type valve operating unit) will be sent free, upon request to The Cutler-Hammer Mfg. Co., 1298 St. Paul Avenue, Milwaukee, Wisconsin.

Improved Pipe Pusher

The Perfect size Easy pipe pusher was developed by the Easy Manufacturing Co., of Lincoln, Neb., to meet the demand for water companies for a powerful machine to push service pipes through the ground without digging trenches.

This new Perfect size machine is double geared and has two speeds so it



The Perfect, a New Pipe Pusher by Easy Manufacturing Co.

is rapid in ordinary work, yet when hard pushing is encountered or when large pipes are to be pushed, the machine can be put in low gear and in this way a greater pressure can be exerted. The machine is malleable and cast iron and drop forged steel. It is equipped with three pilots and will handle from ¾ to 2½ in. pipe. These pilots are all hollow so that water under city pressure can be put right up to the front end of them. In hard or dry soil this reduces the power required to push pipe at least one-half.

Following are specifications relative to the new Perfect:

Length of track 60 in. Weight of track 100 lb. Length of carriage 21 in. Width of carriage 15 in. Weight of carriage 125 lb. Shipping weight 280 lb. Double driving gears, double the power. Two speeds for different work and soils. In low speed, one man can push over 100 tons. In high speed he can push 40 to 100 feet per hour. Drop forged, heat treated vise jaws which positively hold the pipe. Machine is made of malleable iron, cast steel and rolled and drop forged steel. Handles ¾ to 2½-inch pipe.

New Use of Road Guard

The American Wire Fence Company of Libertyville, Ill., have developed new uses for American Life Net Guard.

An increasing number of municipal officials are finding it advantageous and advisable to protect properties such as parks, golf links, playgrounds and similar areas from promiscuous trespassing by automobiles. Such areas

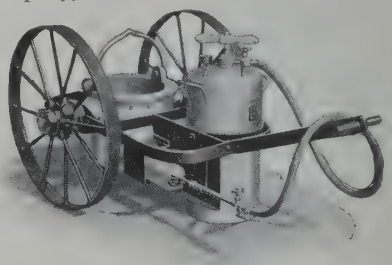
American Life Net Guard Prevents Road Encroaching on Municipal Golf Course

being primarily intended for recreation, automobiles not only damage the grounds but offer serious menace to life and limb.

An installation of American Life Net Road Guard as manufactured by the American Wire Fence Company protects such grounds from motor traffic but does not restrict pedestrians. The company will be glad to offer the aid of their experience along these lines to anyone asking for it.

Littleford Develops Lead Furnace

A new portable lead melting furnace, manufactured by Littleford Bros., Cincinnati, O., increases the efficiency of the pipe laying gang. Water works departments find that the torch-type oil burner not only melts lead very rapidly, but it can be easily detached



New Lead Melting Furnace by Littleford

and used to melt lead compound from old joints.

Littleford lead melting furnaces are made in 250, 350 and 450-lb. sizes. Both portable and stationary outfits are available.

Copper Service Pipe Developments

The past year, according to the American Brass Company, has witnessed a more widespread use of flexible copper service tubes with compression fittings for underground service lines for waterworks.

As rust constitutes a great menace to water distribution systems, one of the foremost requirements sought in pipe for service lines is corrosion-resistance, both internal and external. This, coupled with the need of strength, ductility and ease of installation, has brought about the increased demand for flexible copper service tubing.

Furnished customarily in straight lengths or coils, all the work required for an installation is easily done on the job. A hacksaw is suitable for cutting to any desired length. This tubing can be connected directly with the corporation stop without a gooseneck and easily bent to avoid underground obstructions. For casual bends, flexible copper service tubing may be worked cold by hand, and where a sharp bend is required a bending jig proves entirely satisfactory.

The freezing hazard, risk of pipe

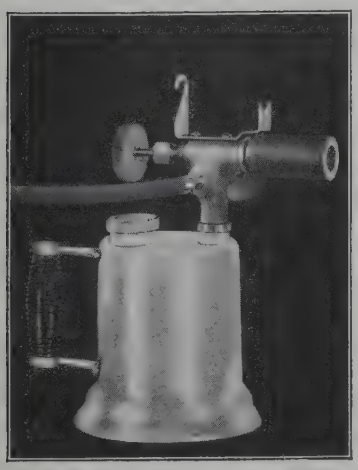
bursting from expansion in cold weather, is always a problem when ferrous service pipes are used. Strength and ductility render copper or copper alloys highly resistant to ill effects from freezing; the ductility will safely compensate for a change of as much as 15 per cent in the diameter of seamless copper tubes, it is claimed.

With modern street paving the costs incidental to replacing services installed beneath permanent highways is a serious consideration. Copper service tubes cannot rust, and consequently are not subject to stoppage because of rust accumulations. A smooth inner surface insures a clear, unrestricted flow at all times.

With a view to increasing the corrosion-resistance of this material, The American Brass Company, of New York, deoxidizes all seamless flexible copper service tubes. Smaller sizes of Anaconda tubing may be used with an ample margin of safety for working pressures up to 200 pounds. Detailed information regarding dimensions, physical properties, etc., of cold drawn copper tubes may be had by asking the above company for its publication C-9.

New Blow Torch Announced by Electric Sprayit Co.

The Sprayit blow torch, new in principle, design and construction, has just been announced by the Electric Sprayit Company, Inc., of South Bend, Ind. Due to the originality of its operation and design, there is no need to pump



Sprayit New Blow Torch

it, no priming and no preheating. A hot, blue working flame is instantaneously available for the job at hand simply by turning the valve and striking a match.

In addition to having the advantage of burning common kerosene instead of costly high test gasoline, the Sprayit blow torch actually produces 30 per cent more heat with the low priced fuel than others can produce with gasoline. As pumping and priming have been dispensed with, there is no chance to have dangerous fuels dripping from the torch. Due to a complete pressure break-up of the fuel, there is 100 per cent combustion and no carbon deposit.

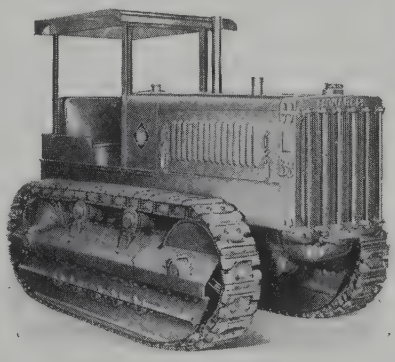
This new torch is so designed that it may be attached to any air supply. Hundreds of mechanics and tradesmen who need both a blow torch and a spraying outfit for their work, have found many distinct advantages in the Sprayit combination set, which consists of a complete electric Sprayit with compressed unit and the Sprayit blow torch which is interchangeable with the Agitator type electric Sprayit gun.

A New Allis-Chalmers Monarch Tractor

The Allis-Chalmers Manufacturing Company of Milwaukee, Wisconsin, announces a new track-type tractor for production and sales at their Springfield, Illinois, plant, the Monarch tractors division.

This new model is known as the Allis-Chalmers Monarch 35.

It offers a maximum of 36 drawbar



Allis-Chalmers New Monarch 35

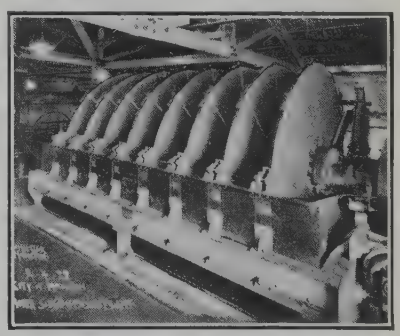
horsepower, three speeds forward and one reverse, 1.84, 2.75, 4.00 and 2.12 respectively. The engine is of a standard Allis-Chalmers type, designed and used exclusively for tractor work, and has four cylinders with removable sleeves set in the block, 4¾ in. bore, 6½ in. stroke. Motor speed under full load is 9.30 r. p. m., and is under governor control. Length over all, including starting crank, is 10 ft., 4 in., width overall is 5 ft. 2 in., height to top of radiator 5 ft. 1½ in. A full pressure lubricating system and an oil Pur-O-lator add considerably to its economical operation.

The track is of extra length as in the larger models, the 50 and 75, providing maximum traction ability, and an even distribution of weight. Features pertaining to the ease and facility of operation and the operator's comfort are incorporated in this machine. Steering is accomplished with a steering wheel and through steering clutches enabling the tractor to virtually turn in its own length. The Allis-Chalmers Monarch 35 is conservatively rated in accordance with the policy of the Allis-Chalmers Manufacturing Company in always maintaining an adequate reserve for peak loads. In general design, construction, and appearance, it is similar to the Allis-Chalmers Monarch 50 and 75 Tractors.

Activated Sludge Filters

The activated sludge process of sewage treatment still holds a strong position in the sewage disposal field and has been definitely adopted by a number of municipalities.

Continuous vacuum filters for de-



American Continuous Filter Installed at Houston Sewage Disposal Plant

watering the sludge formed have been continuously improved by the Oliver United Filters, Inc., of Chicago.

Activated sludge has proven a usable fertilizer, and, when recovered by filtration on continuous vacuum filters and subsequently drying to about 10 per cent moisture in rotary dryers, it has assisted in paying the cost of operating sewage disposal plants by those who have installed this system.

Recent improvements have developed a material increase in filter capacity over original results. A reduction of the moisture of the solid as discharged from the filter, and elimination—or at least a material reduction—in the tendency of the filter medium to become plugged and impervious to further filtration are results of improvements.

All of the above mentioned improvements are due to proper conditioning, control and mechanical handling of the activated sludge and have been demonstrated as being practical and obtainable by several plants.

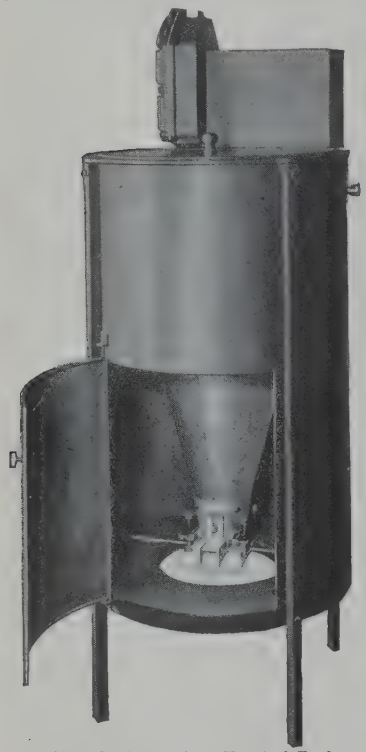
The city of Houston, Texas, using the activated sludge process, filters and dryers, is obtaining results more favorable than originally expected and is having no trouble marketing the fertilizer.

The sludge delivered to the filter at this plant averages around 99 per cent moisture and the solids as discharged from the filter about 77.5 per cent moisture. Capacity runs around 0.623 lb. per square foot of filter area per hour on the basis of 10 per cent moisture solid.

W & T Announces a New Chemical Feeder

Wallace & Tiernan Company, Inc., of Newark, N. J., have just announced their latest dry chemical feeder known as Type O. This feeder, which is the product of five years extensive study and research, has many novel features.

Designed essentially as a low capacity feeder, it has an unusually wide



Wallace & Tiernan Dry Chemical Feeder

operating range and may be used for either fine or relatively coarse chemicals. The minimum rate of feed averages 0.1 lb. per hour for all chemicals. The maximum varies from 40 to 80 lb. per hour, depending on the chemical handled.

Perhaps the most novel features of design are the flexing mechanism of the hopper, the oscillating spout and the convenient, accurate adjusting mechanism. The sides of the hopper are flexed by means of levers near the top which alternately pull in and push out the sides. This method of agitation positively prevents arching and keeps the contents of the hopper moving downward. A vertical agitator is provided for use with light chemicals.

The discharge from the oscillating spout is in the form of a ribbon and the rate of discharge is determined by the length of ribbon pushed off the feed plate at each stroke of the spout. The spout stroke is regulated by a hand wheel having a 100 division circular scale. This long scale, which makes two revolutions in covering the full feed range, makes adjustments easy and accurate. In addition to the spout stroke adjustment the cross section of the chemical ribbon may be varied.

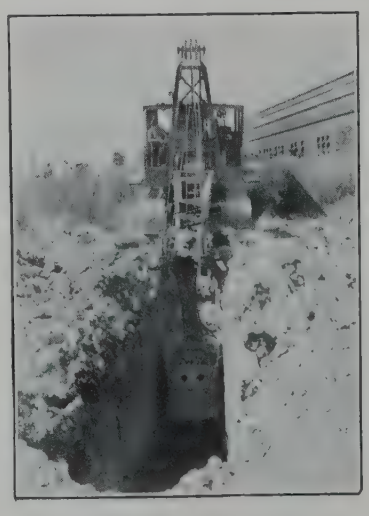
The equipment is operated by a 1/6 hp. motor. The gear case is completely enclosed. The gears run in a bath of oil. Bearings exclusive of the gear case are fitted with special felt washers to keep oil in and dust out. The equipment is enclosed, and is thereby dustproof. It is adaptable for overhead feed with either direct or solution discharge to the point of application. When solution feed is desired a circular solution pot is provided. The water enters the pot at a tangent and the solution is discharged through a central overflow outlet. High velocity and violent agitation makes the chemical solution with a minimum of water. Baffles are provided to prevent flooding.

Bucyrus-Erie Announces D-2 Drag Shovel

The Bucyrus-Erie Company of South Milwaukee, Wis., have brought out a new drag shovel which they call their model D-2.

This machine is a diesel equipped unit which is the result of their 49 years of experience building excavating equipment. The diesel engine on this 1-yd. drag shovel is a 4-cycle, 4-cylinder engine with 6½ in. bore and 8½ in. stroke. It runs at 550 rpm. No priming and preheating is necessary according to the manufacturers. In starting they state, the engine is rotated from an air reservoir and, with the opening of a fuel valve, it delivers full power at once.

On the D-2 diesel drag shovel two of the outstanding features are the ruggedness of the front end and its extreme simplicity. Long life of cable is brought about by the fewest possible bends in the rope and good-sized



Bucyrus-Erie New D-2 Drag Shovel

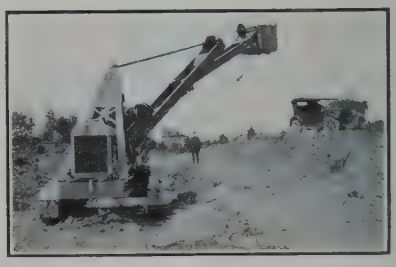
sheaves. Fewer sheaves mean greater power for actual digging and faster overhauling of cables—a faster cycle.

D-2 drag shovel dipper is built with a heavy extra arch. It takes the thrust of the boom and dipper handle and gets away from the spreading of the dipper that causes delays with ordinary dipper construction.

The long chisel-shaped reversible teeth are held without bolts or rivets in wedge-shaped sockets. This tooth is easy to sharpen and replace.

Fundom Shovel Improved

The Fundom Hoist & Shovel Company of Lima, Ohio, have developed their machine now to the point where it serves as dragline, crane, clamshell, shovel and trench hoe. The 12-ft. boom is constructed of 8-in. channels reinforced with plates and ties. The crowding mechanism is operated by double-pad special lined clutch, driving



Fundom Shovel on Road Grading Job

link chain to support shaft, which is provided with two steel, machine cut, pinions meshing with steel, machine cut, rack on dipper handle.

The machine is powered by a Fordson tractor or electric motor. It travels at 2½ mi. per hr. on treads which are 9 ft. 6 in. long, equipped with Alemite lubricating system.

The boom travels ¾ circle, traversed by worm and worm gear driven sprocket meshing with a stationary link chain provided with a shock absorber. Dipper is 1/3 cu. yd. capacity.

King F. P. Water Meter Improved

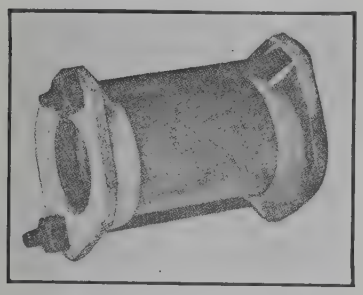
Union Water Meter Company of Worcester, Mass., recently celebrated the sixtieth anniversary of its incorporation by producing the King F. P. (frost protected) meter, which experts agree overcomes former weaknesses in design and construction.

Among the marked advances of this new meter which users of meters will immediately recognize are the position of the thrust roller, an eccentric which locks the disc chamber in place and the use of monel metal pins and lock screws which yield to excessive pressure, such as frost.

The same type of meter is also being produced with split case and is known as King S. C. meter.

Snell Improves Easy-On Threadless Pipe Couplings

The George H. Snell Company, Attleboro, Mass., announces that they are now making their line of couplings and tees of heavier construction throughout. Stronger ends combined with seamless

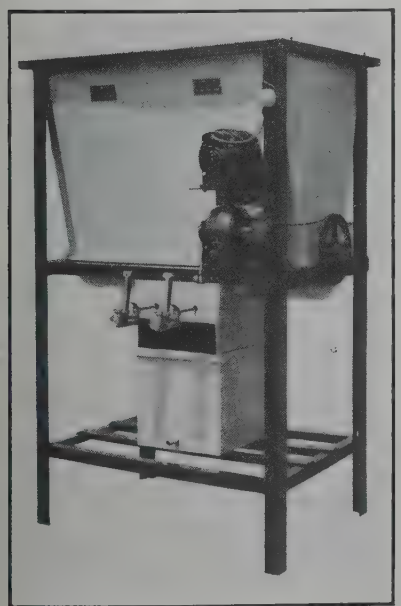


Snell Easy-On Threadless Pipe Coupling

steel tubing enables them to guarantee this new coupling to stand the strain of 250 lb. pressure. Especially recommended for repairing breaks, and making meter connections. Descriptive literature will be sent on request.

Multiple Type Dry Chemical Feed Machine

It has heretofore been necessary to install a separate dry chemical feed machine for each chemical used in a water purification plant. E. W. Bacharach & Company of Kansas City, Mo., have recently placed on the market a multiple type dry chemical feed machine that involves entirely new patented principles of operation. This device



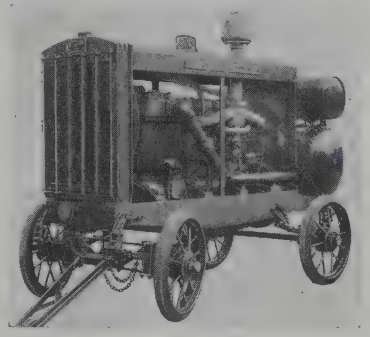
Bacharach Machine for Feeding Two Chemicals

will accurately feed any number of dry chemicals simultaneously in the same or in different amounts. The machine may also be used to feed several different amounts of the same chemical to separate points of application. The same principle of construction is carried out in building a machine for feeding three or more chemicals.

Some of the advantages of installing a single unit machine that will do the work of a number of individual devices are reduced initial cost of apparatus, decreased installation expense, saving of space and power, and less repairs and depreciation. The multiple machine may be calibrated and regulated in the same time that it takes to perform these operations on a single feed machine. The multiple feed machine is especially adaptable for use in small and medium sized water purification plants.

New Air Compressor Developed by Independent Pneumatic Tool Co.

The Independent Pneumatic Tool Co., 600 West Jackson Blvd., Chicago, Ill., has developed a complete line of com-



New Thor 250 Ft. Portable Compressor

pressors and contractors' pneumatic tools.

Their new unit is a Thor 250-ft. portable air compressor which, under actual test, it is claimed, delivers 210 cu. ft. of air per minute. It is equipped with the patented Rix super-charger, which enables the piston on its idle or downward stroke to compress the additional air the Thor delivers.

The Thor is direct driven. It has no clutches, couplings or gears. This design makes for simplicity and low upkeep cost. The compressor is low slung and well balanced. All working parts are easily accessible.

The bore is 7½ in. and the stroke is 7 in. The length overall is 10 ft. 10½ in. Height overall is 6 ft. 4¾ in. Width is 4 ft. The Thor compressor can be had in a variety of mountings to suit individual requirements.

The Thor 116-ft. portable air compressor, which delivers 96 cu. ft. of air per minute, will also be shown. The design and construction is similar to the larger unit.

The company's line of contractors' pneumatic tools consists of paving breakers, clay diggers, sheeting drivers, back-fill tampers, riveting hammers and chipping and calking hammers.

Littleford Bros. Announce New Tool Box

Littleford Bros., Cincinnati, O., are manufacturing an all-steel utility service tool box for public service companies and water works departments.

Littleford Utility Tool Box

They stress the safety, convenience and trailing qualities of this box.

Dimensions are: 54⅛ in. long, 36 in. wide and 36½ in. deep. The double cover can be raised from either side —it is flanged down on all sides and is absolutely waterproof. Under the cover is a large double tray for small tools. About halfway down the main section of the box is a shelf 12 in. wide and 54⅛ in. long. The side walls of the box, when opened out, form strong utility shelves.

Strong, low slung chassis cushioned on heavy helical springs, 32 in. by 3 in. rubber tired wheels equipped with heavy duty roller bearings, 1½ in. high carbon steel axle and non-collapsible drop leg are assurances of long, steady service under hard usage.

Littleford Bros., also make a large heavy duty all-steel tool box for public service and highway maintenance work. An all-steel storage box made in two sizes complete their line of tool boxes.

Light Steel Sheet Piling Devised

Wemlinger, Inc. of New York have developed a corrugated sheet pile of light weight steel which is interlocking and easily handled.

With the protection of a driving cap the sheeting may be driven by hand, air or steam without being damaged, so that it can be used repeatedly

Withdrawing Wemlinger corrugated sheeting is as simple and economical as driving it. Its light weight makes unnecessary expensive equipment and high labor costs. The sections, made interlocking by short clips, are separated without damage as easily as they are put together.

Improved Non-Clogging Centrifugal Pumps

In the last few years rapid development of centrifugal pumps for handling domestic and industrial sewage has been made by a number of manufacturers. The satisfactory handling of sewage of all kinds requires that the pump be capable of passing rags, sticks, stones, etc., without clogging and without the use of strainers. Originally it was thought that this could not be done without sacrificing efficiency. Experimentation, however, has shown that non-clogging pumps can be made to approach in performance and dependability the better clear-water pumps.

In this class of apparatus the Economy Pumping Machinery Company, Chicago, Ill., has announced three new non-clogging designs containing numerous mechanical improvements that make for longer life. These new pumps are made in capacities from the 3-in., 100 gpm. unit that will handle 2½-in. spheres to the 10 in. 5,000 gpm. pump that will pass 7-in. spheres. Pumps of all capacities are made in vertical submerged design, vertical open-shaft design, and horizontal direct-connected or belt-driven.

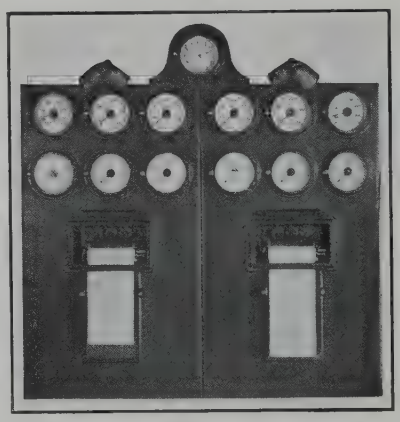
The vertical submerged type is used principally for handling sewage in buildings and industrial establishments where a self-contained unit is desired. The adaption of the non-clogging design to this type of apparatus presented a difficulty in that the impeller hub must be long enough to lock it to the shaft and to receive the countersunk nut. In the new construction the impeller hub is covered with a steel sleeve that acts as the lower journal, making it possible to extend the lower bearing close to the impeller, thus increasing the bearing life and removing all journal wear from the pump shaft. The bearing at the upper end of the shaft is a combination radial and thrust ball bearing mounted in a dustproof housing with double-nut micrometer adjustment. This adjustment makes it possible to drop the impeller assembly to compensate for wear at the impeller inlet.

The open-shaft vertical pump is designed for installation in dry pump chambers such as usually are provided in municipal sewage plants. Instead of operating in the liquid to be pumped, suction pipes are connected to a wet well or chamber. With this type of installation it is possible to elaborate somewhat on the pump design. These open-shaft pumps are of the ball-bearing type with all running bearings above the pump case in a tight grease-lubricated housing. There is provided in the shell a short renewable bearing that is used to take any shock that might occur should a brick or other heavy solid become lodged in the impeller. Adjustment of the impeller is accomplished by means of a micrometer adjusting nut at the upper ball bearing. This adjustment may be made by lifting the bearing cap without removing the coupling from the shaft.

Horizontal pumps of the non-clogging design are used for handling sewage, foodstuffs, paper stock and any other stringy or pulpy material. These pumps may be direct motor driven or belt or chain driven from any suitable power source. They are of rigid design with roller outboard bearings that carry the entire weight of the rotor, there being only a shock bearing within the pump casing.

New Control Panel Announced

The Republic Flow Meters Co. of Chicago announce their new type Republic master panel. This panel makes possible the centralized control of all pumping and storage units, regardless of their location. All records are grouped on the master panel, giving a



Republic Flow Meter Master Panel

complete survey of the operation of all hydraulic units.

Indicating, integrating and recording units can be mounted in any desired combination which will best meet the individual requirements of the installation.

Pipe Line Welder Improved

A pipe line from Jal, N. M., to El Paso, Tex., is being constructed entirely by welding, employing the metallic arc. The pipe itself is fabricated by this method in the plant of the A. O. Smith Corporation in Milwaukee and the line also employs their recently announced Smith Welded expansion joints.

In construction the 30-ft. lengths of pipe are first joined into sections of 5 to 8 lengths, usually 7, by tack welding and are then welded by "the firing line welders," the pipe being turned by tongs as the welding operation progresses. "Firing line" welders are averaging 13 completed welds per 10 hours, it is said. The sections are then

Fuson Welder Moving to New Setup

joined "by the bell hole method," in which a hole is dug for the welder, and he works completely around the pipe as it rests stationary over the ditch.

General Electric, Lincoln and Fuzon welders are on the line. This latter machine is a mobile outfit, being mounted on pneumatic tires, with standard Ford wheels.

The rod being used is the Green Surface Weldite, a product of the Fusion Welding Corporation of Chicago, as is also the Fuzon welder.

Hydraulic Power Electrolyzer Announced

The Direct Oxidation Process Corporation of Philadelphia, Penn., has recently placed on the market a new design of electrolyzer utilizing hydraulic power for the operation of the scrapers. This new arrangement superseded the previous crank and connecting rod type of drive and makes it possible to use larger, and in consequence a less number of electrode plates with a corresponding longer scraper travel resulting in a reduction of about eighty per cent of the moving parts required in former designs. The drive is conveniently mounted above the electrolyzer tank thus eliminating the extra excavation required with the previous models in which the scraper operating machinery was located under the tank. In addition, due to the more compact arrangement, the required length of the equipment for a given treatment capacity is materially reduced resulting in large savings in building costs. The design, in general, greatly increases the accessibility of the interior of the machine, facilitating maintenance and inspection.

Masterwrench Announced

Heller Brothers Co. of Newark, N. J., announce to the field a new wrench that automatically fits all sizes of pipe, bolts and nuts. They call it the Masterwrench. Every Masterwrench is made from carefully heat treated drop-forged, chrome vanadium steel. Its two parts rapidly adjust themselves to the size of the job at hand. It is self adjustable.

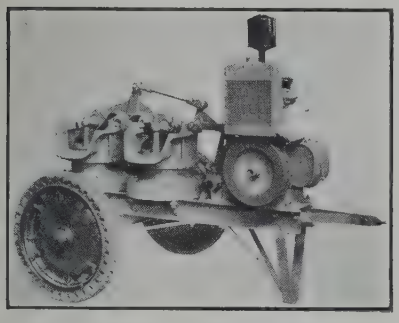
A New Double Diaphragm Pump Unit

The John Lauson Mfg. Co., New Holstein, Wis., announce a new double diaphragm three inch pump unit. A 2½ to 3 h. p. Lauson vertical radiator cooled engine furnishes the power.

Some of the features of this engine are:

Mechanically driven flyball governor enclosed in dust proof housing.

Roller bearing construction; the



Lauson Portable Double Diaphragm Pump

crankshaft is mounted in high grade heavy duty roller bearings which are lubricated from engine crankcase. This construction reduces friction and promotes smoother performance.

Heavy counter-balanced crankshaft; the crankshaft is 1⅜ in. in diameter, balanced with counter weights which reduce vibration to the minimum. A good heavy crankshaft is the backbone of an engine. Heat treated, drop-forged shaft of more than ample proportions is used in this Lauson motor.

Cam shaft; the camshaft is one piece, drop-forged, hardened and ground, and is mounted in large bronze bearings. This type of camshaft will show very little wear and will maintain correct valve action.

Oiling system; the lower base of engine forms an oil reservoir from which the oil is raised by a submerged plunger pump driven by an eccentric on the camshaft. The oil is distributed to all vital parts of engine by splash system.

Connecting rod; the connecting rod is interchangeable with Ford Model T rods.

Piston; the grey iron piston, specially designed for high speed performance is equipped with three rings.

Ignition system; high tension Wico magneto.

Hutto ground cylinder; the Huttto Method of grinding is used by 85 per cent of auto and airplane engine builders, because it positively produces a straight and round bore within tolerance limits of .0005 in. in regular production.

The units will be furnished with any of the leading makes of diaphragm pumps, mounted on two wheel cushion tire trailer or four steel wheel trucks. They will be available for distribution about June 20th.

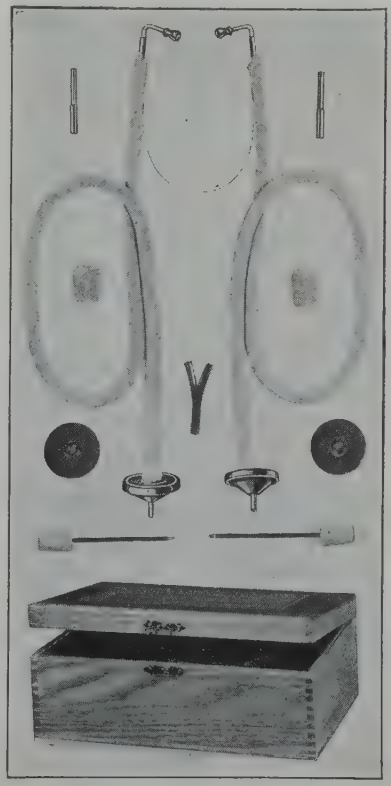
They are compact construction weighing only 775 pounds complete. The engine has a built-in gear reduction. One set of gears, which are carefully guarded operate the jack, which is of the walking beam type.

Sound Locating Tool

A new, improved Twin model Transmit-O-Phone has been developed to assist engineers, operators and mechanics in quickly and economically locating defects in all classes of mechanical devices, pipe lines, and machinery. It is manufactured by the International Metal & Specialty Co. of Berlin, N. J.

The Transmit-O-Phone is not designed to fix anything or to run a Power plant; and like any other high-class tool it naturally takes a little practice for the operator or mechanic to become proficient in its uses. It is exceedingly simple and if used with a little intelligence, the average individual can become very proficient in quickly and accurately locating defects by sound.

Use the corks on the small rods screwed into the point of each amplifier for testing fast moving machinery; where more amplification is desired, use the small round plates screwed into point of each amplifier. The corks on rods are used for clarifying the sounds in high-speed machinery.

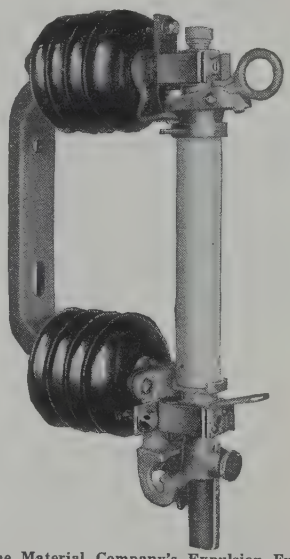


Transmit-O-Phone for Locating Defects

Should there be any problem which the operator or user of the Transmit-O-Phone may not quite understand, no matter what it may be, pipe lines, power plant machinery, motors and gears, etc., if they will drop a few lines to our main office we will be only too glad to have our engineers help them to solve their problem.

Locked Cartridge Expulsion Fuse

The Line Material Company, South Milwaukee, Wis., has brought out a new 15,000 volt, 150 ampere outdoor expulsion fuse known as their locked cart-



Line Material Company's Expulsion Fuse

ridge type. The fuse derives its name from the fact that the cartridge cannot be blown out of the contact clips under heavy short circuit conditions.

The type ED6-15M1 shown in the illustration has the lower casting arranged as a pivoted hinge for the cartridge and is so designed as to prevent the square lower terminal on the fuse cartridge from moving away from the contact clips. The cartridge is securely locked in the closed position by means of a positive catch just below the top contact clip. The catch is held by means of a bronze spring and cannot be disengaged except by pulling the ring handle downward. The top cartridge terminal is equipped with a knurled cap and the lower one cast with a guiding fin and equipped with knurled contact screw. A small L-shaped projection is fastened to the lower square terminal block on the cartridge for use in connection with a combination lift and pull stick.

The contacts are spaced on 12-in. centers, are double spring clip type, insuring ample and uniformly distributed pressure. The top contact clips are the full floating type, insuring proper alignment at all times.

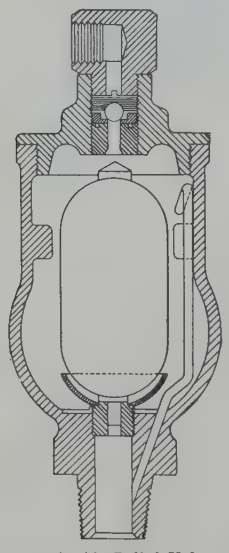
The U-shaped mounting is of galvanized malleable iron and has, it is claimed, a 20,000-volt one piece insulator at each end cemented thereon and allowed to set under steam, insuring a perfect bond.

The cartridge tube is furnished either of bakelite or fiber. The bakelite tube is provided with a special high heat resisting lining which by a special process is made an integral part of the tube. The tubes can also be furnished with an outer porcelain tube for protection from the weather. Fiber tubes are always furnished with the porcelain outer tube. These fuses are described in the company's new catalog No. 28-A.

Apco Automatic Air Relief Valve Improved

Within the last few months a new and improved automatic air relief valve has been brought out by the Automatic Primer Company, Chicago, makers of Apco Primers for centrifugal pumps.

This new air relief valve has proved useful in three different applications, namely, to centrifugal pumps, piping systems and various types of tanks or vessels. The valve is a simple device



Apco Automatic Air Relief Valve with Ball Inserted

which passes air in or out but closes immediately on liquids.

On centrifugal pumps, single or multi-stage, the valve automatically vents the pump casing of air which if not removed would prevent the pump from picking up its load. In large pumping systems where the several pump casings are connected to a vacuum tank, the insertion of an Apco air relief valve between each pump and the vacuum tank will prevent any liquid being taken over when air is evacuated from the pumps and suction lines.

The function of the valve on pipe lines in buildings or on cross country lines is to vent air from such lines whenever summits occur since air pocketed at these high points will otherwise lower the capacity of the line or even entirely block the flow of liquid. The valve serves certain types of fluid tanks and vessels in the same manner.

The Apco air relief valve is constructed of nickel plated cast bronze with a non-collapsible copper float. It is made in 3 sizes adapted to the majority of conditions. For further information on operation of this unit, write to Mr. Bradford, Automatic Primer Co., Chicago, Ill.

Agitator Drives in the Water Works Field

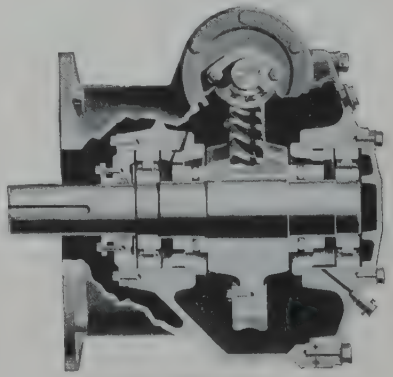
The Agitator drive speed reducing unit has found favor in filtration plants, sewage disposal plants, water purification plants and many other places where the introduction of some form of speed reducing equipment is required.

To meet these growing demands for a compact enclosed unit drive for operating mixers, agitators, paddles, etc., Foote Bros. Gear & Machine Company of Chicago, has added a complete line of vertical worm gear speed reducers. These worm reducers of the vertical type are made in two different types, either the type W commercial worm or the Hygrade worm reducer.

I X L speed reducers are fully enclosed, self-lubricating and dust-proof. Because there are no exposed moving parts they are safe. They conserve space and improve working conditions.

The vertical speed reducer of either the W or Hygrade type permit the use of standard speed motors which are less expensive than vertical slow speed motors and makeshift combinations of gears, chains or pulleys, according to the manufacturer.

The vertical worm gear speed reducers are similar to the Standard horizontal type reducer, except that a flange base is provided so that the vertical reducer is designed to lay on its side with the driving shaft at the right, the worm gear revolves in the horizontal plane and the slow speed shaft is in a vertical position. This shaft can be extended upward or downward, as the conditions may require, so that the reducer can be located under or above the machine to be driven.



Foote Speed Reducer

The construction of these reducers is similar to the Standard type reducer embodying a cast iron case, treated to prevent flaking, with a removable top cover.

Removable end plugs with oil tight stuffing glands and oil seals at each end of the worm. The base is cast integral with the case to provide suitable mounting either on the floor or hanging from the ceiling.

The worm is made of a high grade alloy steel, carbonized, hardened, ground and polished. The worm gear can be furnished either of semi-steel or bronze. Bronze is recommended by the manufacturer because of lower coefficient of friction with less heating losses and longer life.

These machines, either the Standard type W or the Hygrade type, are fully enclosed, self-lubricating units, that require little attention, except the occasional replacement of the oil.

Ball thrust bearings are provided at each end of the shaft to take up any upward or downward thrust. They are compact, noiseless, efficient, dependable units; built to meet every modern agitator problem.

Rawhide Packing for Water Works Use

This is an opportune time to call the attention of the superintendents and water works engineers to the advantages of using Rawhide packing on their pumps, both centrifugal and reciprocating, and their valve stems in all lines of work.

How Mabbs Rawhide Packing Is Shipped

A great many do not appreciate the advantages of Rawhide packing for water works use. Rawhide packing is nearly anti-frictional and its great advantage is that it is too soft, when saturated, to hold the particles of grit upon its surface, but they work back into the body of the packing, thus preserving the metal surfaces from wear and cutting. The manufacturers of

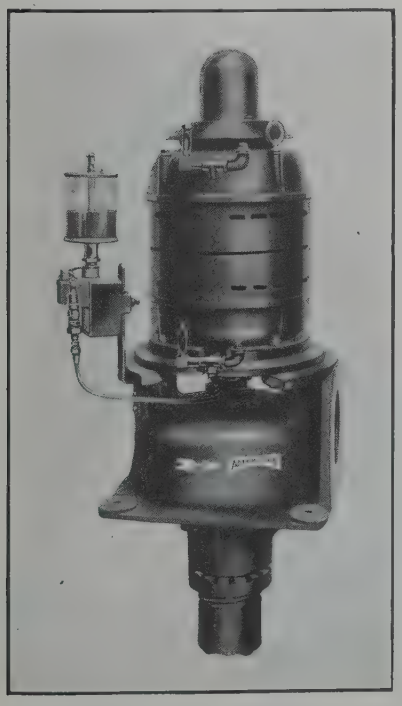
this packing claim there is nothing equal to their Rawhide packing for handling raw water or water where there is any sediment or sand in it. It is claimed that this packing has been used for twenty years by the United States Government on their hydraulic dredges.

Another comparatively recent line which has been brought out by the Mabbs Hydraulic Packing Company of Chicago, is their line of Rawhide meter washers for packing the stems of any kind of water meters. There Rawhide washers are claimed to be superior to cork washers that have been extensively used in the past. The advantages claimed by the manufacturer of these washers are that they are practically anti-frictional and never become hard or glazed and will last for years.

Small Bore Well Turbines Developed

The American Well Works announces their new 6-in. and 8-in. deep well turbines. These turbines have been built in response to a demand for a turbine to fit smaller bored wells. The deep well turbine consists of the turbine head proper, which is the driving unit, the supporting pipe, which encloses the driving shaft, and the turbine itself, which consists of the number of stages necessary for the specific requirements.

The turbine head consists of the vertical motor mounted on a rigid and compact base. The thrust bearing of the motor is designed to carry the load of the line shaft and impellers.



American Deep Well Pump

To the turbine is attached the supporting pipe, to the lower end of which is attached the turbine proper.

The turbine proper is a special style of the turbine type of centrifugal and is designed with the special features that have made American deep well turbines so reliable and efficient.

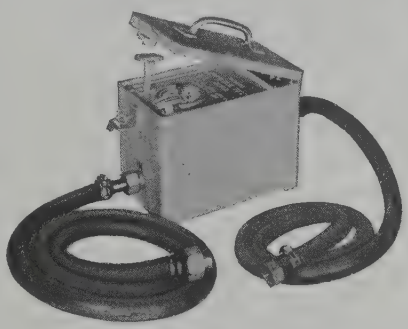
All bearings are oil lubricated by gravity feed from the surface, the gravity feed being electrically controlled.

Provision is made for complete drainage of all waste oil and water leakage and the discharge pipe is located above the floor level, which permits of easy access.

Engineering data and construction details of these turbines may be had from the engineering department of the American Well Works, Aurora, Ill.

Portable Test Meter Announced

A new portable test meter has recently been put on the market by the Badger Meter Manufacturing Company,



New Test Meter by Badger

manufacturers of water meters, Milwaukee, Wis.

This new portable test meter was developed in the engineering laboratories of this company.

The Badger portable test meter is a complete and self-contained unit of light weight, making it possible to be handled and operated by one man and with the connections set up in a practical way which permits of attachment to the service meter or when testing from hose pits in a very limited time. It will consistently and accurately check a given amount of water passing through the service meter, indicating the error either plus or minus, slow or fast on the service meter.

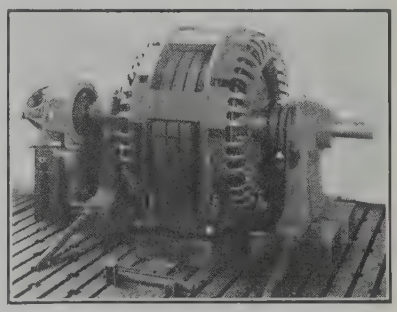
This new portable test meter makes it possible for all meter services to be checked regularly and thereby effect big economies and increased revenue, due to the increased efficiency on the service meters.

This portable test meter is a tried and proved product and has been put on the market only after years of experimental and research work in the Badger Meter Engineering Laboratory.

Structurally Fabricated Motors Announced

Fabricated steel, first used in the construction of low speed synchronous motors, is being extended rapidly by the Westinghouse Electric & Manufacturing Company of East Pittsburgh, Pa., into the high speed motors and vertical low speed motors generally used for water works pumps.

This new type of construction is particularly well adapted to building large units. A mechanical design of known and maximum strength can be produced and the construction is such that effective radial ventilation can be obtained.



Westinghouse 600 hp., 1,200 rpm. Motor for Mounting on Pump Bed Plate

Laminations are securely held between the end plates by through bolts. The end plates are further supported by struts welded between them and supporting fingers prevent loose and noisy laminations.

The advantages of adjustable speed drive and the synchronous motor high efficiencies have been secured, to a great extent, in the two-speed synchronous motor. This consists essentially of two standard synchronous motors of different speeds mounted on the same shaft and each with its own control equipment, electrically interlocked so that either unit may be operated depending upon the speed desired. The control is also arranged so that it is impossible to connect both units to the line at the same time.

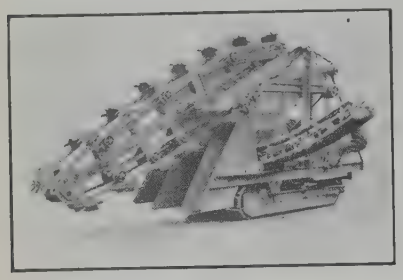
Another interesting development is the use of the reduction gears with both single speed and two-speed synchronous motors to secure the less expensive and higher efficiency high speed motor. The total cost per motor and gear unit is usually equal to or less than for the low speed motor only, and the efficiency of the unit, including gear loss, is as good or higher than for the low speed unit.

A further development has been the mounting of the synchronous motor on the extension of the gear unit pinion shaft. This method uses the engine type motor with the motor rotor overhung, tends to simplify the unit, reduce floor space required for mounting and makes the motor readily accessible.

Parsons Improves Excavator

The Parsons Company of Newton, Iowa, give the following relative to their trench excavator:

All of the main mechanism is enclosed in one gear case, gears being machine cut and case hardened. The



Parsons New Model 31 Excavator

shafting is turned and ground, mounted on anti-friction bearings, both of the roller and ball type. All gears run in an oil bath. The traction drive gears are also enclosed in an oil tight gear case. It is the highest type of construction known in the manufacturing field. It reduces the amount of friction loss as well as reducing the amount of wear and tear on the machine.

When the first machine was built it was put on actual construction work and has already gone through a grueling test period.

Ateco Hydraulic Bulldozer

The Ateco hydraulic bulldozer, recently announced by the American Tractor Equipment Company, is constructed of steel throughout, electrically welded and sturdy enough in all parts to withstand without damage the full pushing power of the tractor.

The Ateco hydraulic bulldozer consists of a heavily reinforced bowl, or blade, extending across in front of the tractor and connected to the tractor trucks through heavy, box-section side arms, one on each side of the tractor, which pivot on pin brackets attached on the outer sides of the tractor truck frames at a point where the rise and fall of the treads when working over rough ground will least affect the position of the blade. A structural steel framework is attached to the tractor through already existing bolt holes which supports at its front end a bell crank assembly. This is connected to the blade through chains, and a hydraulic cylinder with piston rod attached to the central arm of the bell crank for raising and lowering the blade through hydraulic power secured from a pump driven by the power take-off shaft of the tractor through a special 4-way valve.

Tractor Equipped With Ateco Bulldozer

The hydraulic control of the Ateco bulldozer permits the driver of the tractor to accurately raise or lower the blade instantly by means of one control lever located just in front of his seat, in the same manner that the hydraulic hoist on a dump truck is operated.

There are no parts of the Ateco hydraulic bulldozer that in any way interfere with the drawbar of the tractor; in fact, the Ateco bulldozer is frequently used in conjunction with the Ateco hydraulic dirtmover, both bulldozer and dirtmover being attached to the one tractor at the same time. When it is desired to remove the Ateco bulldozer to use the tractor for other purposes, this can be done in a few minutes by pulling the two pins locking the side arms on to the pin brackets and taking two clevis pins out of the chain links connecting the blade to the crank assembly at the front of the tractor.

The Ateco hydraulic bulldozers are manufactured by the American Tractor Equipment Company of Oakland, Calif., recently organized to build bulldozers and dirtmovers manufactured under the McMillan Patents, over 150 of which are now in use.

Trackson Announces Bulldozer

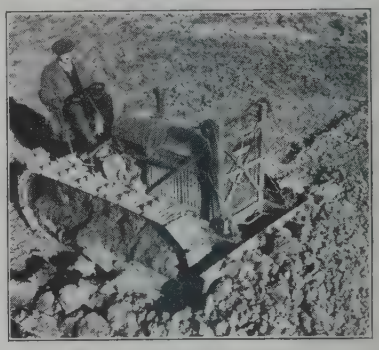
Power, speed and economy for dirt moving operations are provided by the new Trackson bulldozer, which is a recent addition to tractor equipment.

This bulldozer is manufactured by the Trackson Co., Milwaukee, Wis. It is designed especially for mounting on the Model DH Trackson McCormick-Deering crawler tractor, providing an efficient, economical unit for back-filling sewer trenches, ditches, etc., and many other similar jobs.

Like all other Trackson equipment, the bulldozer is built for heavy duty, and its extraordinary strength guarantees day-after-day reliability. The blade is mounted in such a way that the thrust or push is taken by the crawler frame, eliminating undue strains on the tractor.

The mechanical hoist used in the Trackson shovel, loader and crane is also incorporated in the Trackson bulldozer. The same principle is used in most big shovels, loading and lifting machines, a fact which attests to the efficiency of this hoisting arrangement.

This similarity of the hoisting assemblies and frames of all Trackson front-end attachments permits the ready interchangeability of these machines, which is an important advantage in that it enables the owner to use the same power unit for many different jobs. For instance, when the Trackson bulldozer has been used for backfilling a trench, the bulldozer may be removed from the tractor and the loader or shovel mounted in its place.

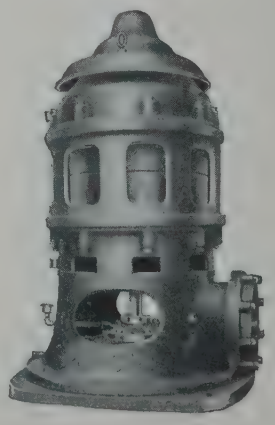


New Trackson Bulldozer

The Trackson crane is another important tractor attachment which is a time and labor-saver for water works and other public works departments. It may be used for unloading or carrying pipe, and for lifting and transporting heavy weights of all kinds.

Pomona Utilizes Water Lubrication

The Pomona water-lubricated superturbine pump, manufactured by the Pomona Pump Company, Pomona, Calif., has developed one type of turbine pump which, it is said, is especially desirable for city or municipal use because it is lubricated by water in



Pomona Westinghouse Unidrive

the well. This method of lubrication eliminates the use of all oil or grease below the surface, thus preventing contamination of the water. In addition to providing uncontaminated water, this method of lubrication forms a protective film that makes the bearings practically indestructible and prevents frequent pump troubles, officials say. Pomona pumps occupy little space, re-

quire no pit, are noiseless and vibrationless—all advantages which make these pumps especially suited to municipal use, the manufacturers believe.

Where it is desired to pump water from the well into tanks or reservoirs, it can be done quickly and economically with Pomona turbine pumps, it is stated. Water can also be delivered direct into mains under pressure; or direct into a pressure tank by automatic control, making it unnecessary for an operator to start or stop the pump.

To provide Pomona pumps for practically any conditions of pumping, the manufacturers have made them available in a variety of sizes and capacities and with either motor or belt drive. The type most widely used is the Pomona-Westinghouse Unidrive, which is furnished in all sizes up to and including 100 hp. A great convenience of this type is the electric motor built into the pump head and an automatic starting and stopping device which operates by merely pushing a button.

Wells as small as 4 in. inside diameter can be operated by these pumps and any number of gallons—from 25 to 4,500 per minute—are available, according to size of pump. If the water level recedes, it is only necessary to add additional pump column or stages.

Stover Improves Oiling System

On previous Stover engines there were from 12 to 15 oil holes or cups which required an oil supply at least once an hour, in some cases more frequently. The newest model Stover engine carries its supply of oil in a crank case and a splash lubricating system provides for its constant automatic distribution to all working parts. All hand oiling is eliminated.

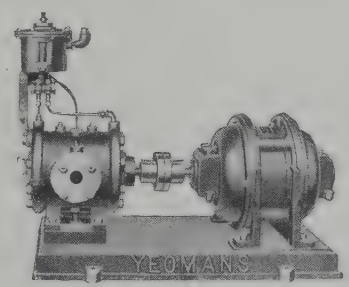
Stover engines are particularly adapted for operating such machines as concrete mixers, pumps, hoists, sawing outfits, etc., where the air is apt to be filled with dust, sand, sawdust or other foreign matter which naturally falls upon and clings to the ordinary open-type horizontal engine. The oil tight crank case enclosure on the new Stover product forestalls all trouble and wear caused from such conditions.

This new engine is interchangeable with all Stover engines of the same size, already in the field.

Literature fully descriptive of this product can be had by addressing the Stover Manufacturing & Engine Company, Freeport, Ill.

Yeomans Rotary Air Compressor

A new type of air compressor has been developed by a 30 year old manufacturer of pumping machinery, Yeomans Brothers Company, 1423 Dayton St., Chicago.



Yeoman's Newest Rotary Air Compressor

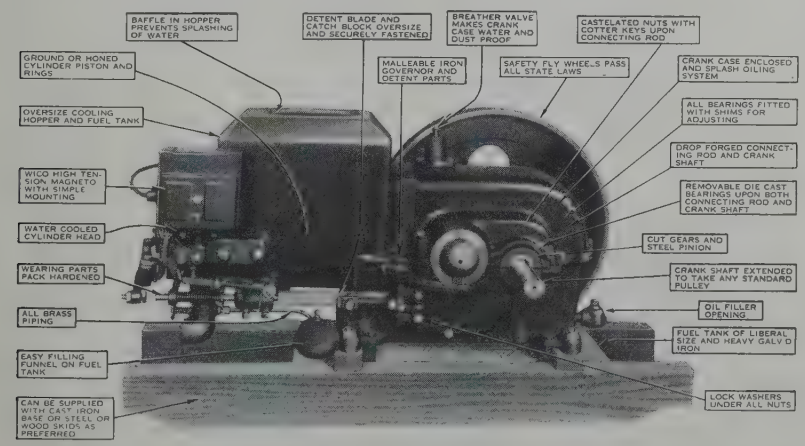
The compressor is of the rotary, multi-vane type and is quiet running, automatically oiled and direct connected to motor or other prime mover. There are no belts, pulleys, gears or valves, small space is required, wear is practically eliminated and because of simplicity of design, is light in weight.

Because of the rotary multi-vane design, the Yeomans compressor produces a continuous, nonpulsating flow of air in contrast to the pulsating flow of reciprocating compressors. This continuous air flow permits, in many cases, operation on air lines without storage tank.

No water seal is employed and the machine is lubricated with oil, so that there is no corrosion of working parts. The shaft is sealed by means of metallic packing rings with automatic spring adjustment, so that stuffing boxes are eliminated.

Automatic lubrication is effected by the use of Yeomans oil economizer, a device which lubricates only when compressor operates, and insures thorough and positive oiling at all times and eliminates the possibility of corrosion and prevents waste of oil.

The compressor is suitable for any air service in municipal or industrial work where pressure up to 50 lb. is required.



BAFFLE IN HOPPER PREVENTS SPLASHING OF WATER
DETENT BLADE AND CATCH BLOCK OVERSIZE AND SECURELY FASTENED
BREATHER VALVE MAKES CRANK CASE WATER AND DUST PROOF
CASTELATED NUTS WITH COTTER KEYS UPON CONNECTING ROD
GROUND OR HONED CYLINDER PISTON AND RINGS
MALLEABLE IRON GOVERNOR AND DETENT PARTS
SAFETY FLY WHEELS PASS ALL STATE LAWS
CRANK CASE ENCLOSED AND SPLASH OILING SYSTEM
OVERSIZE COOLING HOPPER AND FUEL TANK
ALL BEARINGS FITTED WITH SHIMS FOR ADJUSTING
DROP FORGED CONNECTING ROD AND CRANK SHAFT
WICO HIGH TENSION MAGNETO WITH SIMPLE MOUNTING
REMOVABLE DIE CAST BEARINGS UPON BOTH CONNECTING ROD AND CRANK SHAFT
WATER COOLED CYLINDER HEAD
CUT GEARS AND STEEL PINION
WEARING PARTS PACK HARDENED
CRANK SHAFT EXTENDED TO TAKE ANY STANDARD PULLEY
ALL BRASS PIPING
OIL FILLER OPENING
FUEL TANK OF LIBERAL SIZE AND HEAVY GALV'D IRON
EASY FILLING FUNNEL ON FUEL TANK
LOCK WASHERS UNDER ALL NUTS
CAN BE SUPPLIED WITH CAST IRON BASE OR STEEL OR WOOD SKIDS AS PREFERRED

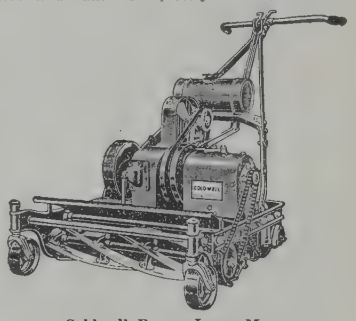
New Stover Industrial Engine

Coldwell Power Lawn Mowers

The Coldwell Lawn Mower Co., Newburgh, N. Y., give the following general specifications of their mowers for use on municipal and waterworks maintenance jobs:

General Specifications

Two-cylinder 4-cycle gasoline engine for Twin-30 and L Twin models. One-cylinder 4-cycle for L Jr. and Cub models. Water cooled with radiator and fan. Completely enclosed and automatically lubricated with oil pump. Crank shaft mounted on Timken tapered roller bearings. Tillotson automobile type carburetor. Bosch high tension magneto. Governor control. Abundant reserve power for grades. Channel steel frame on mower chassis. Full width two-section drive roller with differential. Separate clutch for drive roller and for cutting knives with individual control levers on handle. Automobile type clutches; no adjustment required. Transmission and clutches enclosed. Five blade cutter. Roller bearings throughout. Alemite-Zerk force feed lubrication. Simple and economical in operation and thoroughly dependable. Grass box, also riding sulky may be had as extra equipment.



Coldwell Power Lawn Mower

Coleman Sewer Rod Point

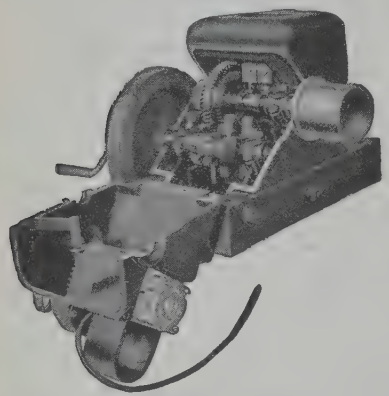
Allen J. Coleman of Chicago has developed a sewer rod point that will roll its way through stoppages and around bends. It is constructed of two roller wheels, rolling at right angles to each other. This new article, the manufacturer states, has been tested out and found to be an efficient tool.

The manufacturer also announces an improved lead point runner. The clamp is furnished with pouring funnel. It has a long fibre solid core and two braided jackets of high heat resistant, strong yarn. The foot plate is formed so as to hold clamp in place on pipe until asbestos rope is drawn tight and locked by lever clamps.

New Portable Engine Has Many Interesting Features

A new line of gasoline-kerosene engines in ratings from 1½ to 7½ hp. recently announced by Fairbanks, Morse & Company of Chicago, incorporate a number of interesting features. While the most radical departure from previous construction is in the all-enclosed self-oiling feature, the new engine is quite different in appearance from other small engines of its type.

The 1½ hp. rating, which is a size



Removal of Two Bolts Permits Opening Enclosure of the Fairbanks-Morse Engine and Exposes All of the Working Parts. Two Speed Arrangement of Pulleys Is Also Shown

used in a wide diversity of drives, such as portable pumps, air compressors, generator saws, grinders, polishers and similar uses, is the most interesting development in the new line. It is less than 16 in. high, 22 in. long and 19 in. wide and weighs 150 lb.

Two pulleys are provided, one of which operates at the engine speed of 1,500 r.p.m. and the other at 750 r.p.m. There is also a mechanical regulator which permits slowing the engine down to 1,100 r.p.m. with, of course, proportionate reduction in horsepower. With the two pulley speeds and the speed regulator it is possible to meet the requirements of almost any type of drive.

An important feature about the new 1½ hp. unit is its simplicity in design. There are said to be 25 per cent less parts than in previous engines of this size. Unit construction throughout makes the cylinder, water hopper, crankcase and bearing supports for both crankshaft and camshaft integral parts of the cylinder and base casting. The engine, with the exception of the magneto, can be entirely assembled on this casting.

Complete protection from dirt, dust, rain and snow is afforded through the fully enclosed feature. By the removal of only two bolts, all working parts, such as the crankshaft, camshaft, bearing, etc., are open to view and inspection.

Removal of eighteen bolts completely dismantles the entire engine.

Self-oiling is accomplished through a special lubricating system which literally drenches all working parts in oil. No grease cups are required.

The base casting serves as an oil reservoir. The bearing caps have caps to collect the oil which drips from special baffles located directly above on the crank case cover.

One of the special mechanical refinements is the method by which leaking of oil is prevented. Felt retainers on the crankshaft and camshaft—return oil grooves on these shafts—and a special crankcase breather eliminates all possibility of leaking oil. The crankcase breather, further, does away with compression in the crankcase. Instead of forcing the oil out at the gaskets, the special breather sucks in all oil collected at the gaskets by maintaining a vacuum within the crankcase.

Improved Speeder Shovel-Crane Announced

The Speeder Machinery Corporation, Cedar Rapids, Iowa, manufacturers of ½-yd. full revolving, convertible gasoline shovels, introduced and showed for the first time at the road show, the improved Speeder, model B-3, much faster and more powerful than previous models.

The improved Speeder, model B-3, has a hoist line speed of 180 ft. per min., a swing speed of more than four revolutions per minute and a travel speed of 1½ actual miles per hr. in high gear, and .55 mile per hr. in low gear. In low gear the machines will climb a 35 per cent grade.

The patented Speeder direct cable crowd is used. The working principle is the same as in previous models, but it is improved in view of the fact that two short cables rather than one long cable is used, thus necessitating the replacement of a short cable rather than a long one in case of breakage. The speed of the crowding action also has been increased.

Among other improvements found on the improved Speeder model B-3 is a greatly improved ultra-positive steering mechanism that permits sharp or gradual turns under most adverse conditions; heavier construction throughout; electric lights and starter as standard equipment; a new style steel cab; six carrier trunnions for the upper body rather than four, as in previous models, and a motor with 4¼x5¾-in. bore that develops full 53 hp.

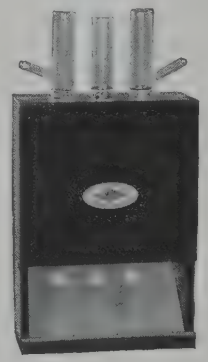
The improved Speeder, model B-3, as a shovel has for standard equipment a boom 18 ft. in length and as a crane carries either a 30 or 35-ft. boom and the working load is 10,000 lb.

Further information may be obtained from the Speeder Machinery Corporation, Cedar Rapids, Iowa.

Model B-3 Recently Announced by Speeder Machinery Corporation

New La Motte Equipment

La Motte Chemical Products Co., McCormick Bldg., Baltimore, Md., are now putting out all standards for water analysis in closed Nessler tubes with



La Motte Colorimeter for Nessler Tube Comparisons

polished tops and bottoms. The tube is filled through a side arm which is then sealed off, preserving the standard from contamination of any kind. Standards for color, nitrogen, chlorine, total iron, nitrite, nitrate, ferrous iron and manganese are available.

This special colorimeter is 7 in. long, 4 in. wide and 9 in. high. A piece of etched glass is placed directly below the bottoms of the tubes, and below this is a mirror set at an angle of 45

deg. An open Nessler tube containing the test sample is placed in the central hole and two consecutive standards in the holes on either side. Holding the upper ends of the tubes toward a source of daylight, the comparison is made by looking into the mirror. The colorimeter should be used in all comparisons with the sealed Nessler standards.

A complete new series of indicators has been developed to cover the pH range 9.6 — 13.6. These new indicators are especially useful for pH control in water softening.

Large Collapsible Swimming Pool

A portable collapsible swimming pool made of a new and almost indestructible Wunder cloth is one of the latest products of Hill-Standard Co. of Anderson, Ind.

The pool when set up is 40 ft. long, 10 ft. wide and 57 in. deep, holding 12,100 gal. of water. It is easily trucked to any point, and quickly set up and taken down. Angle iron supports keep it rigid. The Wunder cloth wall laps smoothly over the iron top rim and down, being laced to the top rim. Bathers are thus fully protected from all metal.

This new pool has a variety of uses. It is already in use in Eastern tourist camps. It is equally desirable for summer camps, groups of summer homes, near the water as well as inland. Its advantages will be appreciated for carnivals, amusement resorts and beaches, where beginners learn before going into the lake or ocean.

It makes fine provision of bathing facilities in parks, recreation grounds and clubs lacking permanent installations. It is also adaptable as a temporary sectional municipal pool. The low cost brings it within reach of many institutions which have had to do without pools.

It is claimed for this new pool that it is practically non-crackable, being protected by a finish in a new special process which holds the flexibility in exposure to all weathers. The pool is fully described in the new Hill-Standard water sports catalog, a copy of which will be sent free on request.

Hill-Standard Portable Swimming Tank

New Universal-35 Developed

The Universal-35 is a ½-yd. capacity machine, built by the Universal Crane Co., Lorain, O.

It is mounted on a two-speed center drive crawler. Speed changes and crawler steering are controlled from the operator's position, regardless of the position of swing of the turntable.

Universal-35 Two-Speed Crawler

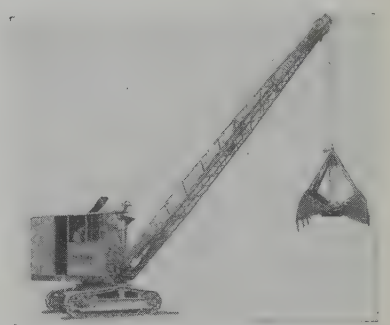
The superstructure proper is of the same design and construction as has been built for the past several years as the Universal Truck Crane. The superstructure can be mounted on either the two-speed crawler or a 5-ton motor truck chassis and is readily transferable from one to the other.

The boom equipment offered on the Universal-35 consists of crane booms 16 to 56 ft. long, ½-yd. center drive shovel, backdigger booms, clamshell and dragline bucket equipment and skimmer. All boom equipment is readily interchangeable.

New Orton ⅝-Yd. Convertible Shovel

One of the developments in shovel design by the Orton Crane & Shovel Co., Chicago, is their model A convertible ⅝-yard shovel. Its light weight, small over-all clearances and high mobility make it particularly suitable for excavating and grading contractors, material yards, industrial plants and similar applications.

Chief among the features of the Orton model A machine are the well balanced design, the scientific distribution of material, the use of alloy steel for all power shafts and gears, and the extension of cab so that the work can be seen from both sides of the operator's position. These features contribute greatly to speedy operation, and the sturdy construction insures a machine of endurance. Strength and rigidity of the base are obtained by building it of rolled plates and shapes which are thoroughly riveted and electric welded. The use of structural steel combines lightness with uniformity of material. Electric welding gives the necessary rigidity for supporting shafts and bearings, and for withstanding operating strains.



Orton Model A 6-ton Crane Equipped with Orton ½-Yard Excavating Clamshell Bucket

Flexible crawling treads of the spring type absorb shocks and protect the operating mechanism from undue strains. The springs distribute the weight of the machine uniformly over the treads so that it is not concentrated when the machine travels over uneven ground, logs or other obstructions. The treads

are self-cleaning and will not clog with loose dirt or stones. The model A can also be furnished with road wheels or for mounting on standard auto-truck chassis.

All of the power shafts are made of alloy steel, and are turned and ground. Each power shaft is in a horizontal position, and can be removed without interfering with any of the others. Interchangeable phosphor-bronze bushings are provided for all bearings. Gears are made of special heat-treated alloy steel, and all spur gears are cut from solid blanks.

An abundance of power is provided by the heavy-duty 53-horsepower Hercules motor, which is provided with an electric starter as standard equipment.

The model A can be furnished with shovel, crane, dragline, ditcher or skimmer attachment, and can be changed from one to any other in the field in less than two hours, it is claimed.

A feature of the shovel, the manufacturer states, is the positive crowding action, the full power of the engine being transmitted directly to the digging edge of the dipper by the patented gear-driven crowding device. The shipper shaft is driven by a slip friction adjusted to release before the main clutches slip or the engine stalls. In operation, the crowding clutch is thrown in completely, and a constant thrust is maintained on the dipper, the slip friction acting to absorb shocks and jars, and to prevent killing the engine or transmitting undue strains to the power clutch. The entire crowding mechanism is integral with the boom, thus facilitating changes to other attachments.

The model A crane has a lifting capacity of 6 tons at a 12-foot radius, and, when equipped with a standard 30-foot boom, handles a ½-yard bucket throughout its operating range. Booms 35 or 40 feet long can be furnished for hook operation.

The patented Orton T head on the ditcher attachment gives maximum pull back when the dipper stick is nearly horizontal, and minimum pull when the scoop is in a digging position. This arrangement affords great digging power and also serves to snap the scoop back quickly when dumping. Two drums mounted on the boom, one on the top leading to the hoist drum and the other leading to the scoop, eliminating a sheave at the scoop, and give straight, direct pull.

The dragline has a 30-foot, lattice-type boom, and the fair-leader slides so as to give the most direct lead possible to the drum, being carried on a bronze-bushed, cast-steel lead sheave, with guard sheaves properly balanced so as to produce a minimum amount of wear on the cable. It handles a bucket with a capacity of ½ cubic yard.

The model A skimmer is provided with a steel boom, from which the scoop is suspended by means of bronze-bushed steel rollers. It has an effective length of travel of 11 feet, and the scoop has a capacity of ½ cubic yard, with a width of 30 inches, although special widths can be furnished.

New Dorr Equipment in Sewage and Water Works Fields

The Dorr Company of New York has introduced within the last year or so three new equipment units for the more effective mechanical solution of such frequently met sanitary engineering problems as coarse screening, grit removal and washing, and agitation or mixing. Each new unit is allied in a sense with existing Dorr sanitary equipment in that it precedes and supplements the Dorrco screen, Dorr traction clarifier and Dorr sewage digester.

The Dorrco bar screen consists essentially of two main parts:

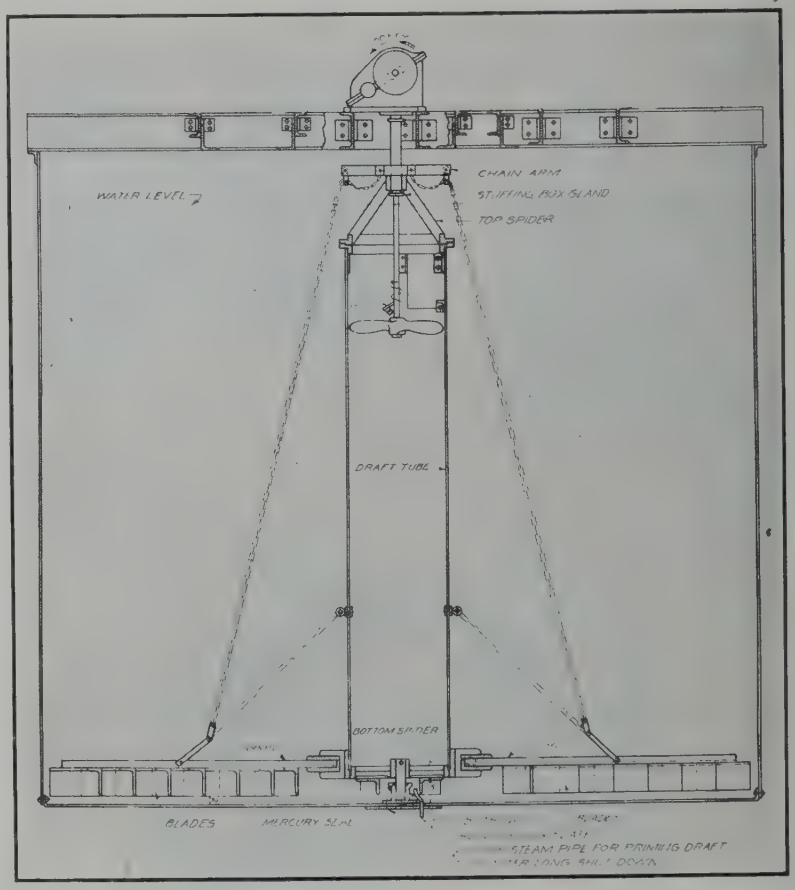
1. The stationary bars forming the screen.

2. The cleaning mechanism for removing the screenings which are deposited on the bars.

The straight bars forming the screen are similar to those used in plain bar screens, and usually are ¼-in. by 3-in. bars, placed in the channel at an angle of 60 deg., the opening between the bars depending on local conditions.

The cleaning mechanism consists of raking mechanism with supporting frame, drive mechanism with supporting frame, and rake scraper for removing the screenings from the raking mechanism.

The Dorr Detritor is an automatic, self-cleaning grit chamber, for general use in place of the conventional grit settling troughs at sewage disposal plants. The name Dorr Detritor has been taken from the word "detritus," which is usually used to refer to the inorganics in sewage. This machine performs all of the functions of the grit settling channels and in addition automatically collects and washes the grit, delivering it finally in a clean, dewatered condition to a suitable receptacle.



Sectional View of New Dorr Impeller Agitator

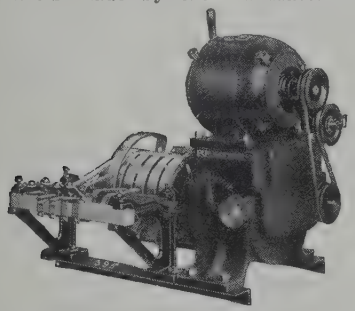
The Dorr Impeller Agitator is the most recent equipment development of the Dorr Company in the water works field. This unit is designed to give that type of efficient mixing which is so important in the chemical softening of hard waters and the chemical dosing

of turbid waters. A feature of considerable importance is its ability to turn over a large volume of water at a velocity which does not break up flocs.

Reco Traffic Control

The accompanying illustration shows one type of Reco variable control which has been the "Mechanical Traffic Officer" of a great many of the Stop and Go signals throughout the U. S. A. since automatic traffic regulation was adopted.

The adjustment of this control as well as that of other types of variable controls made by the manufacturers,



Reynolds Mechanical Traffic Officer

The Reynolds Electric Company of Chicago, is of the thumb screw type, permitting the regulation of the speed of the drum during one-half of a revolution. This enables the officer in charge of traffic to regulate east and west or north and south traffic to suit the peculiar conditions of the intersection.

Assuming that the traffic control is set for 30 seconds north and south or one cycle in 60 seconds, the thumb screw enables changing to either 40 to 20 seconds of any point in between or vice versa. In other words, a 33⅓ per cent variation faster or slower in either direction can be secured by this feature of the Reynolds variable traffic control.

The Reynolds Electric Company also manufacture flashers for blinkers, flashing beacons, stop or warning lights, airport lighting needs, alarm signals, etc. Information bulletins are furnished cheerfully upon request.

Fusee Screw Water Level Recorder Improved

Julien P. Friez & Sons, Inc., of Baltimore, announce the development of the Air Fusee screw water level recorder. The instrument records water level variations on a continuous roll and will operate continuously for 60 days without attention.

Outstanding features claimed for the instrument follow:

Simplicity, the design embodying a minimum of moving parts without delicate mechanisms.

Ease of operation, with dependability and accuracy of performance under adverse conditions.

Fusee paper drive, which avoids the complicated system of rollers common to other designs and provides means of adjusting the paper drive to eliminate time errors.

Record placed directly on original roll, before the paper has had a chance to shift laterally or otherwise alter its original condition.

Endless screw pencil drive, so constructed that the pencil carriage will reverse at either end without changing the rate of lineal motion at the point of reversal.

Positive drive float wheel, which eliminates all gage height errors due to slipping or improper seating of the float cable.

Jewelled clock, weight driven, with dial and hands for indicating time, connected to driving mechanism by universal joint and removable without tools.

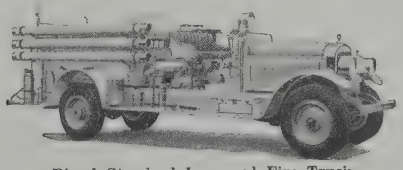
Easy removal of sections of chart, when records covering short intervals of a day or week are desired.

The distinctive feature of the recorder, and that from which it received its name, is the slightly conical, spirally grooved pulley, known in clock making as a "fusee," the function of which is to drive the paper at a constant lineal speed.

Pirsch Improved Fire Truck

Peter Pirsch & Sons Co. of Kenosha, Wis., announces an improved 1,000-gal. fire pumper.

The motor, transmission, axles, rotary pump, chassis and fire equipment design and construction is improved, evolved after years of study of fire department problems. Great strides have been made in motor design since the



Pirsch-Standard Improved Fire Truck

first pumpers were built. The motor in this 1,000-gal. pumper delivers its full rated capacity of 1,000 gal. at 120 lb. per pump pressure from suction. The Pirsch-Standard 1,000-gal. pumper delivers its rated capacity from suction at 120 lb. net pump pressure at 1,350 rpm. of the motor or only 67 per cent of the maximum, which means a reserve of 33 per cent. When operated at close to its safe maximum operating speed it has pumped 1,312 gal. of water at 127 lb. net pump pressure from suction.

The truck comes fully equipped. It has a rotary type pump with stainless steel shafts, synchronizing gears, positive dependable relief valves, also auxiliary force feed oil pump, built in, which lubricates all moving parts requiring lubrication.

Pressed Brick Important Item

The new Howard's Bend plant of the St. Louis, Mo., water works system at present includes a group of buildings consisting of high and low pressure engine houses, boiler house, coal receiving house, filter house, head house, coagulant house, and two gate houses at the settling basins.

The interior of these buildings necessarily must be of the most scrupulous sanitary nature. The architects, Messrs. Study & Farrar, solved the problem so far as the wall surface was concerned by the use of enamel brick. In order to avoid the glare of white enamels, the Hydraulic-Press Brick Company of St. Louis developed especially for the architects and under their direction, a soft special shade of gray which provides to be both pleasing to the eye and attractive in appearance, practically eliminating glare. These great wall expanses, however, are not left without a relieving trim and, for this purpose, the company furnished the architects with a transparent speckled buff enamel brick which is used around all windows and doors, and not only for a base but also for all horizontal and vertical trim lines. It may be interesting also to know that the pits in both the high and low pressure houses, where the big pumps are installed, are lined from top to bottom with gray enamels.

New Type Hydrant Devised

Shand and Jurs Co. of Berkeley, California, have developed a new hydrant especially applicable to climates where freezing does not occur. All of the operating parts are in the head. Instead of shutting the water off at the base of the plug it is allowed to be in the head continually and to enter the hose connection by opening a valve which closes that connection. The valves operate directly on the hydrant hose connection passage ways.

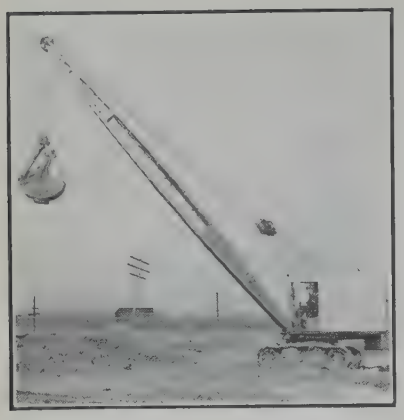
The hydrants are made with various sized openings.

Lorain 55, a New 1-Yd. Machine

Recent developments in the excavating and material handling fields have created a distinct need and demand for a 1-yd. machine of the calibre, construction, speed and design of the 1¼-yd. Lorain-75, according to the Thew Shovel Co., of Lorain, Ohio.

All the advantages of Thew Center Drive principle, as proven by the Lorain-75, direct power, rugged strength, high speeds, smooth, positive three lever control, and high standards of construction and materials are duplicated in the new 1-yd. Lorain-55. All three power shafts can be engaged at once, giving three simultaneous operations, independently controlled.

The 1-yd. Lorain-55, while it incorporates the successful design features



Lorain 55, Thew's New 1-Yd. Machines

of the Lorain-75, is not a machine "cut down" or "built up" from other capacity units. Rather, it is an entirely new superstructure designed and built throughout of a size, strength and weight to most efficiently handle a 1 cu. yd. struck measure.

On bin charging, material rehandling, stock-piling, and on large sewer clamshell excavations and backfilling, the Lorain-55 offers an improved 1-yd. crane.

Due to an easily adjustable slip friction on the holding drum, the Lorain-55, as a clamshell, is operated by only two hand levers and two foot pedals. Booster bands on the hoist clutch controls insure easy, responsive operations.

Harnischfeger Builds Side Wheel Trencher

A new side wheel trenching machine, recently added to the line of excavating equipment manufactured by Harnischfeger Corporation, Milwaukee, promises to be an exceptionally popular model with public utility companies.

The Pacific Gas & Electric Company, San Francisco, Cal., has just purchased one of the new wheel type machines for use on a 76 mile pipe line job near San Francisco. It is averaging approximately 1,300 ft. of trench per eight hour shift—cutting to a depth of 4½ ft. and 28 in. wide, the manufacturer states.

A side wheel trench of this type has several distinct advantages for city work. The cutting wheel, being mounted at the extreme left hand side of the machine, permits cutting exceptionally close to a line of telegraph poles or close to the street curb. The side wheel feature is also a valuable aid when cutting trench close to the edge of a highway. The cutting wheel projects 2 ft. beyond the outer edge of the crawler, making it possible for the entire traction to remain on the hard road or pavement—thereby avoiding the expense of planking up a low side.

The machine is equipped with a 55 hp., heavy duty Waukesha engine which consumes approximately 35 gal. of gasoline per eight hour shift. The wheel has a cutting range of 20 to 28 in. in width and can dig trench to a depth of 5 ft.

Kupferle Tests Hydrants

Recent tests on the new Kupferle fire hydrant shows it is to pass all requirements of the Associated Factory Mutual Fire Insurance Companies.

This hydrant is manufactured by the John C. Kupferle Foundry Co. of St. Louis, Mo.

The barrel is made in three sections. The top section embodies a stuffing box for the operating stem and serves as a cap for the hydrant. The middle section is a cylindrical casting provided with a flange on each end and with two outlets spaced 90 deg. apart near the upper end. The outlets are provided with 2½-in. bronze hose nipples, which are threaded and pinned in place.

The seat ring casting is of bronze and is threaded into the upper part of the inlet barrel section.

Two pair of vertically extending bronze guides located diametrically opposite each other are cast on the upper part of the seat ring casting to guide the valve mechanism.

A 5/16-in. drain hole is provided in the seat ring opposite the annular groove in the upper part of the lower barrel section, this hole being closed by the drip valve when the hydrant valve is in the open position. The lower end or face of the seat ring is beveled at an angle of 45 deg.

The diameter of the waterway through the seat ring is 5½ in.

Capillary Comparator

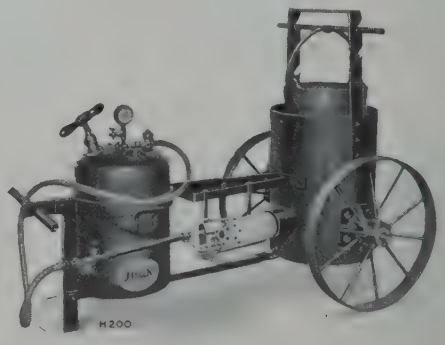
Eimer & Amend of New York announce the development of a comparator for hydrogen ion determinations. The Hellig comparator uses permanent, non-fading glass standards, but the glasses are rectangular plates and are enclosed entirely in a glass housing, acid and dust-proof, thus forming a convenient color scale. The capillary tube, which contains the solution to be tested, together with the indicator, is held by a metal rider which moves along the color scale. This rider has a milk glass back for diffusing the light, an opening in front for securing the proper color field, and two openings at the margin for reading either the horizontal or the vertical pH valves, depending on how the rider is placed on the scale. Each color scale is marked horizontally and vertically with the corresponding pH value for readings in either position of the apparatus. The color comparison may be made and the pH value scale can be read from one point of observation. As the color fields are close together a very good match is obtained. The metal rider can be used with any of the glass color scales.

This outfit is very handy for measuring hydrogen ion concentration for minute quantities of test solution, only one drop being required.

New Hauck Lead Melting Furnace

The new line of Hauck combination melting furnace and portable torch equipments, on legs and on wheels, are designed for heat control, a new and exclusive Hauck feature. Instant and positive heat control under the pot is secured by the new slide-rail burner construction. For full heat, simply push burner forward on slide-rail; for less heat, pull burner away from furnace. Each size of burner gives an intense,

P. & H. Side Wheel Trencher Recently Developed



Hauck Slide Rail Lead Melting Furnace

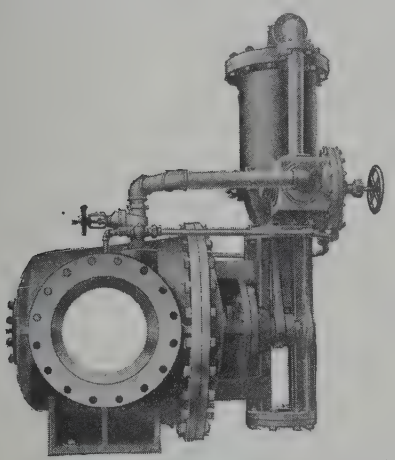
reddish blue, clean and steady flame from 1,600 deg. to 1,800 deg. F. with no smoke.

Write Hauck Mfg. Co., 141 Tenth St., Brooklyn, N. Y., for bulletin No. 101 illustrating and describing the above lead melting combinations.

Outboard Type Valve Announced

The advent of the centrifugal pump in pumping stations introduced some interesting problems to the waterworks field. Particularly were engineers in this field concerned with check valves. Several different styles of check valves were tried to meet varying conditions.

The Automatic Cone Valve Company of Chicago, have developed valves which have the inherent features that



Automatic Cone Valve Company's Outboard Type of Valve Recently Developed

are of utmost importance to the operating engineers. The fact that when the cone valve is in full open position, the waterway is similar to a piece of pipe and reduces frictional resistance to a minimum. This question of friction plays a very important part in the design and layout of plants and pipe lines; wherever obstructions are eliminated the increase in pressure can be evaluated on a dollars and cents basis which reflects itself into increased efficiency.

The Automatic Cone Valve Company first produced what they now term the Inboard type of valve which first made its appearance at the American Waterworks Convention in Chicago, Illinois, during June of 1927. At that time, the engineers were very much impressed by its quick and easy operation. Later developments naturally tended to simplify construction and improve the operation. The accompanying picture very clearly shows the circular waterway without obstructions. All the operating mechanism is "outboard" and can be inspected without interfering with operation. In fact, every part of the hydraulic mechanism can be removed and replaced without shutting down the pipe line.

The cone valve has the inherent advantage of having a plug which is mounted in bearings and revolves freely on these bearings during operation without the seats coming in contact with any other metal. It is a surface of revolution fitting into another surface of revolution, and therefore, can be lapped into its own seat, making the tightest valves known. For operation in gritty water, the rotation of the plug has a selfcleaning effect. The accompanying picture shows the automatic cone valve which is composed of two distinct mechanisms. The hydraulically operated cone valve and the control mechanism which properly times the opening and closing of the valve eliminate shock and water hammer. Cone valves are made for electrical, manual or hydraulic operation. All automatic cone valves are hydraulically operated. Manually operated and electrically operated cone valves are very adaptable for use as stop valves controlling distribution systems where pipe diameters are of large size.

The automatic cone valve is so designed that it does the double duty of both a stop and check valve. This operation is accomplished by installation of the control valve having two Pitometer connections through the valve proper which register the condition of flow against the diaphragm unit control valve. The movement of this diaphragm distributes the power water to the proper side of the hydraulic cylinder which in turn opens or closes the cone valve itself.

New Laboratory Media

In the not so distant past much importance was ascribed to the spore-forming anaerobes as indicatory of sewage pollution. Today, however, the chief interest of the water bacteriologist in the spore formers is due to their interference with the presumptive test for Esh. coli. Spores may persist for indefinite periods in polluted waters. Their presence, therefore, does not indicate recent or dangerous pollution, nor does it distinguish between the decomposition of animal and plant wastes.

Bacto-Brilliant Green Bile and Bacto-Brilliant Green Bile, 2% Special have been developed by the Digestive Ferments Company, Detroit, Michigan, cooperating with Committee No. 1 Standard Methods of the American Water Works Association, as two dehydrated culture media for the purpose of eliminating the confusion resulting from non-confirmable presumptive tests. Both the dye and bile act as inhibitory agents, preventing the development of the spores, but permitting the growth of the gram-negative, non-spore forming, lactose fermenting organisms.

Bacto-Brilliant Green Bile is prepared according to the formula of Muer and Harris. The dehydrated medium has been used with satisfaction by many sanitarians. Bacto-Brilliant Green Bile, 2% Special, is made up to contain a reduced content of bile with the dye present in a 1:75000 concentration. This medium also is very satisfactory for the presumptive test.

The use of these media in the water bacteriologist's laboratory is still a tentative procedure. Much study has already been, and is still being, undertaken to determine the value of the inhibitory action. Results would seem to indicate that both of these media are of distinct value, especially with certain types of waters.

Further information on how to manipulate the tests will be furnished by the Digestive Ferments Co., of Detroit.

The Northern Valve Announced

The Northern Pump Company of Minneapolis, Minn., describe their newest development, the Northern Valve. Northern double packed valves are of the stop cock type, packed both at the top and the bottom, a design and construction completely covered by U. S. patents. This valve was formerly known (1921 to 1928) as the Victory FcH double packed valve, made by the Victory Manufacturing Company of Niles, California. Ordinary makes of plug valves (stop cocks) have failed to attain wide general use because of the inherent tendency of plug valves either to stick or to leak, according to the manufacturer.

Northern double packed valves have stuffing boxes located at the top and bottom of the plug, the two points where leakage could occur, and can't keep leaking. They cannot stay stuck. Slight tightening of the bottom packing gland usually will loosen a stuck plug, but if this should fail, a sharp blow on the bottom will certainly jar loose a plug which has become stuck tight.

Northern double packed valves are lubricated by a simple but positive method, insuring correct lubrication of valves used in air and gas lines which carry no liquid and are normally dry. Alemite fittings are installed on valves which require lubrication, at the request of the purchaser. Otherwise the openings will be closed by plugs, interchangeable with the Alemite fittings.

The valve ports are regularly rectangular in shape, of practically the same area as the corresponding pipe. These regular ports are called Smoothway. If the valve is required for throttling service, Diamond ports may be had at the option of the purchaser. Three-way and four-way Northern valves are available, in the Smoothway type, also a line of stream jacketed valves. For further information, address Northern Pump Co., Minneapolis, Minn.

Hydraulic Oil-Power Jacks for Hydraulic Field

For general utility in the water works field the Blackhawk Manufacturing Co., Milwaukee, Wis., announce their hydraulic oil-power, gauge-equipped jacks. These jacks are in favor wherever accurate maximum loads or strength of material must be tested easily and economically.

Jacks with gauges are used to determine weights of loaded trucks; strength of concrete or vitrified pipes; testing concrete beams for bending or shear; sinking piles to pre-determined loads; press work and many other uses where total weights of load, or pressure per square inch is desired.

Blackhawk Jacks can be equipped with gauges of any size or tonnage and with graduations to suit the needs for industrial, laboratory and experimental tests.

Gauges are individually hand calibrated to conform to the Bureau of Standard Specifications for Hydraulic Gauges which means that they must be correct within 2 per cent plus or minus of the reading indicated.

Due to lightness and compactness most Blackhawk jacks can be handily operated by one person on any job. They have double utility as when not in use for testing, the gauge is easily removed, a half inch pipe plug inserted and the jack used for any other lifting work.

New Fire Pump Chlorinator

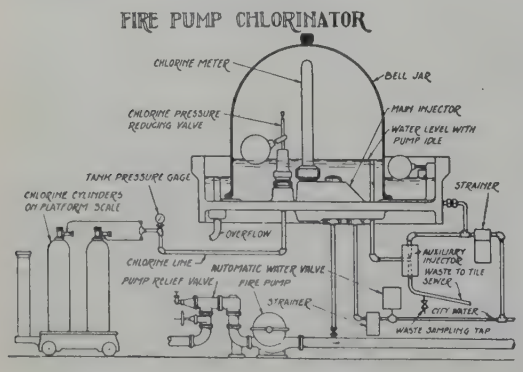
In co-operation with representatives of the fire underwriters and the New York State Department of Health, Wallace & Tiernan have developed a new fire pump chlorinator. The equipment was designed to meet conditions in those industrial plants where it was found absolutely necessary to maintain a cross connection between the fire system from a secondary source and the public water supply. Installations in New York State are in conjunction with factory mutual type double check valve.

The chlorinator used is the standard Wallace & Tiernan vacuum type solution feed equipment. A small auxiliary injector is provided which is operated continuously from the city water system, discharging to waste a small quantity of chlorine solution (1 to 2 lb. per day). Operation at this low rate keeps the chlorinator in readiness at all times for emergency use when the fire pump is put in operation. Water from the fire system supplies the main injector of the chlorinator and automatically feeds chlorine to the fire pump supply at a predetermined rate to assure sterilization of the water. This rate of feed is constant. The chlorinator is set in accordance with specifications of the state board of health. The chlorinator is not sold for installation except under conditions approved by the state board of health.

In practice the operation of the auxiliary injector is checked daily by testing for chlorine in the water discharged to waste. Weekly tests are required in accordance with the requirement of the state board of health. Careful records are kept of the operation of the fire pump chlorinators.

This equipment promises to be a practical solution of the difficult health problem of assuring protection against local cross connections within industrial plants where of necessity a secondary fire water system must be provided.

For further information write to Wallace and Tiernan of Newark, N. J.



Wallace & Tiernan's New Fire Pump Chlorinator

Automatic Pressure Controller

The Electric Controller & Mfg. Co. of Cleveland, Ohio, has developed altitude and pressure regulators for automatic control of pressures and liquid levels which are applicable to the water works and general municipal field.

E C & M automatic pressure control equipments are used with motor driven apparatus for the automatic regulation of water, liquids, air or gases.

These equipments are made in two types designated as altitude regulators and pressure regulators. They differ only in the design of the regulating gauge.

Altitude regulators include a gauge which registers pressure or altitude with a high degree of accuracy. These gauges are practically frictionless and the pointer will respond accurately to extremely small variations in pressure. Altitude regulators are, therefore, suitable for controlling pressure systems where liquid levels of air pressures must be maintained between extremely close limits.

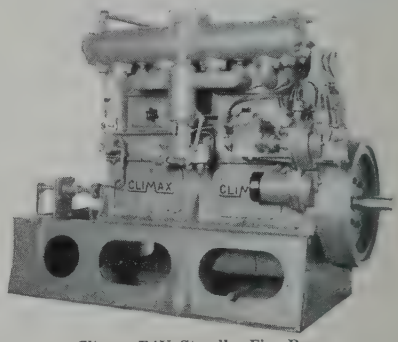
An E C & M altitude regulator panel automatically controls two pumps that discharge into the same tank. This is a very interesting application of the E C & M altitude regulator in that it has many features such as should one pump not deliver sufficient water, the other pump will automatically be started and should one pump become disabled so that it will not maintain the water within the required limits, the other pump will automatically start and the disabled pump will be cut out.

It may also be used in another interesting way in that the pressure of a gas system may be maintained between predetermined limits. The company recently figured on using this regulator in connection with a gas booster pump that was driven by a direct current adjustable speed motor. Should the pressure fall below a certain value, the altitude regulator automatically increased the speed of the motor sufficiently so as to increase the pressure.

Standby Fire Pump

The Climax Engineering Company of Clinton, Iowa, have developed an engine for fire standby service which they call their Model R4U Uunderwriters' Engine.

This engine has been approved by the Underwriters' Laboratories for fire pumps operating at 100 lb. pressure and delivering 500 to 700 gpm., the manufacturer states.



Climax R4U Standby Fire Pump

Climax Model R6U engine is approved for 1,000 gpm. pumps.

Climax Underwriters engines are furnished complete with electric starter, generator and battery, instrument board, including all necessary instruments mounted on engine, water-cooled manifold, stub shaft, vacuum fuel pump and vacuum tank and with or without mounting frame or bed plate, making a complete unit ready to assemble with the pump without additional special mounting and installation engineering.

Blue prints and instructions are furnished with each engine.

Discovering Natural Laws a Specialty

Thousands specialize as teachers of scientific laws where scores specialize in discovering new laws. About the same ratio exists between researchers who merely collect facts and searchers who determine their relationships and significance.

As an illustration of the difference between researchers, consider Nicholson, who discovered the ninth satellite of Jupiter, and Einstein, who found out why Mercury's perihelion revolves about the sun. The one photographed the heavens about Jupiter and found a streak on a plate that showed the existence of a new moon. The other busied himself with no telescopic observations, yet by study of the fundamental physics of motion discovered certain laws that may eventually aid in revolutionizing astronomy. Already Einstein has given to astronomers a formula by which the diameters of stars may be calculated if certain spectroscopic data and mass are securable.

Important as is the work of such men as Nicholson, the observer, far more important is the work of such men as Einstein, the interpreter. While observers are relatively numerous, interpreters always have been, and still are, scarce. Curiously enough, most observers seem to be somewhat jealous of interpreters who undertake to explain what the observed facts mean. At any rate they are prone to ignore or to belittle any new theory that relates to their realm. They act as if they regard the theorist as an amateur who is trying to instruct the professional. This attitude indicates failure to realize that the art of discovering natural laws and the formulating of new theories is itself a specialty. Once that art has been well mastered, its possessor usually is able to make discoveries in many different realms. The professional observer or experimenter in each of these realms often fails to understand how an "outsider" can enter his particular realm, quickly penetrate a mass of data and find a hidden law that binds seemingly disconnected facts into an organized whole. The lack of understanding that such an achievement is possible to men who specialize in theoretical research, perhaps accounts for part of the difficulty that the latter find in securing acceptance of their discoveries by the very men who should be the first to put their stamp of approval upon them.

Illustrative of the attitude of many scientific teachers and observers toward research theorists we may cite Agassiz. When he advanced the theory that a great and prolonged ice age had once existed, and that practically all of northern Europe had been covered with a deep ice cap, a chorus of disapproval arose from teachers of geology, many of whom were good observers. Among them was Prof. Braun, who, having taught Agassiz the little that he knew about geology, was particularly certain that he could learn nothing from this former student. "Stick to your fishes, Louis; stick to your fishes," he cried, for what could be plainer than that only a specialized geological observer could ever hope to discover a new geological principle or law? But Agassiz refused thus to be limited, and steadily continued to pile up evidence in favor of his ice age theory. By instinct he was a theorizer, although his training had made him also a good observer. His greatest delight was in discovering some broad principle, and he found a splendid opportunity for such discovery in the realm of geology. Yet it was not for two generations that practically every geologist in Europe had capitulated to the Agassiz ice-age theory.

For the specialist in the discovery of the causes of effects, science often has no boundary. Having learned how to interrogate Nature successfully in one corner, such a specialist usually finds no difficulty in making her answer his "fourth degree" questioning in the other corners.

More than half a century ago it was recognized by a few discerning scientists that the discovery of natural laws is itself a specialty, as the following quotation shows.

E. L. Youmans, in Popular Science Monthly, November, 1874, on "Spencer and Evolution," said:

"In the scientific world, the accumulation of facts has outstripped the work of valid generalization. For, while men of moderate ability can observe, experiment, and multiply details in special departments, it requires men of breadth to arrange them into groups, to educe principles and arrive at comprehensive laws. The great mass of scientific specialists, confined to their departments, and little trained to the work of generalization are apt to regard lightly the logical process of science, and to decry mere theorizing and speculation. They forget that facts of themselves are not science, and only became so by being placed in true relations, and that the function of the thinker is therefore supreme; while the work of organizing facts and establishing general truths is, after all, just as much a specialty as that of observation or experiment in many branches of inquiry. The prevalence of these narrow views has been unfavorable to the recognition of Mr. Spencer's work by a large class of the cultivators of science; and the more so, as he has been mainly occupied in the highest spheres of generalization. For this reason it is only by the comparatively small number of scientific men, who possess marked philosophic power, that his labors have been justly appreciated."

Need of Further Study of the Boulder Dam Project

The announcement comes from Washington, D. C., that no power company will bid on the electric power to be developed on the Colorado River and that the city of Los Angeles can not obligate herself to the necessary extent without exceeding her debt limit; so the so-called Boulder Dam project seems to have hit a few financial boulders at the very start.

The federal bill that made the government the sponsor for this project requires that sufficient income from the project be assured in advance, to pay not only the operating expenses but to amortize the investment within 50 years. The politicians who "engineered" the bill thought that engineers who questioned the possibility of contracting to sell the power to power companies were "all wet" and perhaps somewhat prejudiced. But the power companies of southern California now refuse to make any sort of bid for power under a contract that binds them for 50 years. They say that already they are generating power by steam at a cost that makes the hydroelectric power unattractive, and that, looking forward to a continued reduction in the cost of steam generation, they dare not enter into any 50-year contract for power. No engineer who has much knowledge as to the cost of generating power by steam would be apt to advise a power company to do anything else than these power companies have done, namely to refuse to sign a 50-year contract for hydro power.

There is one feature about such a contract that has not been discussed by the politicians who sponsored this bill. We refer to the money that will be lost by any purchaser of this power during the period when only part of it can be sold. Let it be assumed that the hydro power plant will be ready for operation 8 years hence. Some one must pay the interest charges on the investment during those 8 years, but we refer not to that big item but to the sequel to it, namely the interest charges on the unused part of the plant after operating begins. Now, under the bill, both these expenses must ultimately be paid by the power companies, cities, etc., that contract to use the plant, for the entire cost of the project must be amortized in 50 years from income received. The interest during construction will probably not be much less than 20 per cent of the cost of the project, and we would not dare advise a power company or city to estimate less than 30 per cent more to cover the "development cost" or sequel to interest during construction, for it is not probable that a full use of the plant would be reached short of 10 years after its completion. A conservative estimate for interest during construction and for subsequent interest on the unused part of the plant would be 50 per cent of its construction cost.

Should it be argued that the growth of southern California would suffice to create a demand for all the power from Boulder Dam during its construction period, the answer is that the power companies would have had to meet that growing demand every year during construction, by enlargments of their existing plants. Hence, when Boulder Dam power becomes available, either the then existing steam plants would have to be scrapped or lie idle; and, in either case, who is going to foot that bill?

As is usual when politicians "engineer" such public projects, the public finds itself in a mess. This project is a problem in engineering and business economics that should never have been made a political issue until it had been completely solved by competent experts. That it had not been completely solved was very plainly stated by the last board of engineers that reported on it. But that report was either brushed aside or misinterpreted by congressmen who were eager to be seen doing something big for their constituents before the next election. They have done something big but not exactly the big something that they thought they were doing.

The editors of "Engineering and Contracting" are of the opinion that the Boulder Dam project should be shelved until at least four entirely separate engineering boards shall have investigated the wisdom of building any such dam on the Colorado River. Where hundreds of millions of dollars are involved, it would not be extravagant to employ every eminent consulting hydraulic and power engineer in America to aid in reporting upon it. Let the "doctors disagree" as much as they may and there will be disagreement enough we may be sure—the first important thing to decide is the economic merit of this project. By securing adequate data, by threshing out the different interpretations of the data by many experts, an important board of engineers appointed by President Hoover can probably reach a correct decision.

It has been urged by the State Engineer of Arizona that Los Angeles can secure an adequate water supply from the Sierra Nevada Mountains. It has been urged by other able engineers that a gravity supply can be secured from the Colorado River by going farther north. It has been calculated that the silting up of the Boulder Dam would so rapidly reduce its storage capacity as to prevent the production of power on a large scale after a few years. It has even been suggested by engineers that a cheaper source of water for southern California is the Sacramento River.

This whole economic problem is by no means a simple one. Indeed, it is so complex that there are grave doubts whether its correct solution has yet been found.

H. P. Gillette

DISTRIBUTOR NEWS

The Distributor's Department in the Gillette Construction Group

Greetings to the Dean of U.S. Traveling Meter Salesmen, Geo. H. Carr

Forty-three years of continuous service in the meter business, as a record not of an organization but that of an individual, is a record deserving of comment.

Dean of the U. S. traveling meter salesmen is a title justly earned by long and continuous service in this field by Mr. George H. Carr, for forty-three years in the meter industry, the past twenty-six being with one company, the Worthington Pump and Machinery Corporation.

Geo. H. Carr in Charge of the Meter Department for the Worthington Pump & Machinery Corporation at Chicago

In August, 1886, Mr. Carr entered the employ of the Union Water Meter Company of Worcester, Mass., as a shipping clerk and by 1890 had advanced to that of traveling salesman. In 1898, after twelve years with this company, he severed his connection with them to travel for two years through the south for the National Meter Company. At the end of this time he entered the Chicago office of the Hersey Manufacturing Company.

In September, 1903, he was placed in charge of the central states meter business for the Worthington Pump and Machinery Corporation, where the first of September he will round out twenty-six years in the service of this company and end his forty-three years in the meter industry.

The picture presented with this story is evidence that Mr. Carr is to break this record by many more years. The Chicago office of the Worthington Pump and Machinery Corporation, where Mr. Carr is located, is at 37 West Van Buren St.

O. B. Avery Company of St. Louis to Handle Monarch Tractors

The O. B. Avery Company of St. Louis, distributors of construction equipment, have recently taken on the Allis-Chalmers Monarch Tractor line. This company has become a factor in the construction industry in the St. Louis territory, through their long established policy of cooperation with the contractor in every phase of his work. The addition of the Monarch Tractor to their already complete line of equipment is in keeping with this plan of cooperation.

In commenting on the new arrangement, one of the officials of the company said: "Allis-Chalmers Monarch Tractors are fast becoming known as outstanding tractors in power and performance due to the advanced design and development made since the Allis-Chalmers Manufacturing Company purchased the Monarch Tractors Corporation a year ago. One of the biggest points of the Monarch is its remarkable ability to keep all feet on the ground and pull—no matter how heavy the load, even under the most unfavorable conditions."

The O. B. Avery Company has a service department well equipped for handling repair work quickly and economically, under the direction of skilled tractor mechanics, and the possibility of loss of time to the contractor due to breakdowns, is cut to the minimum by carrying in St. Louis a complete stock of repair parts.

In addition to the Allis-Chalmers Monarch tractors, the Avery Company represent Northwest Engineering Company, Chicago; Chain Belt Company, Milwaukee, Wis.; Sullivan Machinery Company, Chicago; Buckeye Traction Ditcher Company, Findlay, Ohio; Butler Bin Company, Waukesha, Wis.; National Hoisting Engine Company, Harrison, New Jersey; G. H. Williams Company, Erie, Pa., and other well known lines. The St. Louis offices and

Headquarters of O. B. Avery Company, St. Louis, Mo.

warehouse is located at 1325 Macklind Avenue, where the visitor is always welcome if seeking information concerning any of the products handled by this company.

LaBour Increases Distribution Points in New York Territory

Eastern purchasers of LaBour pumps may now place their orders direct with the New York office of The LaBour Company, or with other distributors representing them.

LaBour products have previously been handled in the New York territory exclusively through Mott and McElrath Engineering Corporation. But, with a view to broadening the distribution service the exclusive feature of the arrangement with this company has been discontinued, although they continue to represent The LaBour Company.

In Mexico

The Pennsylvania Pump and Compressor Company of Easton, Pa., makers of vacuum, centrifugal and air lift pumps and compressors have appointed Wells, Fargo & Company, Express, S. A., Apartado Postal, 361, Mexico City, as distributing agents for the Republic of Mexico.

Distributor Note

Yeomans Brothers Company, Chicago, manufacturers of sewage ejectors, pumping machinery and rotary air compressors, announces the appointment of the Capitol Equipment Company, Bank of Commerce Building, Charleston, W. Va., to represent them in the Southwestern part of that state.

Capitol Equipment will handle a complete Yeomans line, which includes sewage ejectors, bilge or sump pumps, water supply pumps, general service pumps, condensation return pumps and rotary air compressors.

Frank T. Fay

Frank T. Fay, sales manager of the Asphalt Department of the Standard Oil Company of New York, Boston Division, died suddenly in his apartment at the Parker House, Boston, Sunday, May 5th.

Mr. Fay was 70 years old. He graduated from the Worcester Polytechnic Institute in 1878, and had been with Socony ever since, making a notable record of fifty years in the service of the company. He was a pioneer in the road oil and asphalt business in New England. He had been in charge of the department which he headed since its beginning.

United Tractor & Equipment Adds to Membership

The total membership of the new United Tractor & Equipment Company of Chicago has now reached forty, according to a recent announcement of its president, Mr. Milton W. Anderson. Mr. Anderson announces as new members of the organization, the Maine Steel Products Company of South Portland, Maine; the I. B. Rowell Company of Waukesha, Wisconsin, and the Northwestern Manufacturing Company of Milwaukee.

Mr. Anderson states that the announcement of the formation of the United Company for the co-operative manufacturing and marketing of a full line of machinery centering about the United Tractor, built by the Allis-Chalmers Manufacturing Company brought many requests for membership and assignment of territory.

The tractor is being sent out in carlot shipments throughout the country, and Mr. Anderson reports wide interest shown by manufacturers, distributors, dealers and customers in this product which is offered, for the 1929 season, with a full line of implements and industrial equipment, by a group of non-competitive manufacturers, to be sold through similarly functioning distributors.

A Distributor Note from Florida

Some of our readers may not know that the old firm of McDonald and Burgman, formerly located at Jacksonville, Fla., is now operating in different sections of the state as two separate companies. These two companies are now known as the McDonald Tractor-Equipment Company of Orlando and the Burgman Tractor-Equipment Company of Jacksonville.

The McDonald Tractor-Equipment Company covers the southern half of the State of Florida and Burgman Tractor-Equipment Company covers the northern half. They continue to represent the same lines as those carried by McDonald & Burgman, which include: "Caterpillar" tractors. Russel graders, Athey wheels, P&H excavating machines, Killefer equipment, Plymouth locomotives and other lines.

Burgman Tractor-Equipment Company continues to occupy the headquarters of the old company at 8 Riverside Viaduct, Jacksonville.

Two Iowa Firms Combine to Make Armco Ingot Iron Culverts

The Independence Corrugated Culvert Company of Mason City and the Iowa Pure Iron Company of Des Moines are now installing machinery and equipment for the manufacture of Armco Ingot Iron corrugated culverts and accessories at Cedar Rapids, Iowa. The plant will be operated jointly by the two companies.

It is announced that the addition of the Cedar Rapids plant, together with the plants at Des Moines and Mason City, will enable them to give prompt and efficient service to all Iowa points. The address of the Cedar Rapids plant is Box 67.

Flox Company of Minneapolis Takes On New Line of Water Level Control Equipment

Mr. C. S. Childs, general manager of The Flox Company, 430 Oak Grove, Minneapolis, Minnesota reports that they have recently taken on a new line of water level control for elevated tanks. It employs the barometric principle through use of a mercury column, exerting the pressure from the mains through needle valves, which irons out the surges and line pulsations and, accordingly, raises and lowers the mercury level, so that water levels can be maintained within a 1 foot range, if necessary.

The Flox Company have been distributors and service engineers for several years for the National Aluminate Corporation and the International Filter Company, both of Chicago.

Highway Trailer Is Going Strong in Cincinnati

A report published in the City Bulletin of the City of Cincinnati states that Highway Trailers have tremendously increased the efficiency, lowered the cost and improved the service of the department.

In 1927 the City of Cincinnati ordered eight trailers from the Highway Trailer Company of Edgerton, Wis. In 1928 an order was placed for ten, and so satisfactorily have they been working out, the 1929 order is reported to be for forty-four. The accompanying picture shows a train of trailers at work gathering refuse for the City of Cincinnati.

Train of Highway Trailers, One of Many Now Operating in City of Cincinnati

Central Iron & Steel Company's District Offices Announce Change of Address

Central Iron & Steel Company of Harrisburg, Pa., has recently announced changes in the location of its New York and Pittsburgh offices. The New York office formerly located in the Evening Post Building, is now in the new Cunard Building at 25 Broadway, Suite 516. The address of the Pittsburgh office, which was formerly 1606 Commonwealth Building, is now 1721 Oliver Building.

Central "Knobby" non-skid floor plates identifies the products of this company, which also manufactures steel plates of various kinds for the trade.

Change of Address

American Hoist and Derrick Company announces the removal of their Chicago office from the Fisher Building to 1000 Engineering Building, 205 W. Wacker Drive, and of the Pittsburgh office from 604 Chamber of Commerce Building to 901 Farmers Bank Building.

Night View of Plant Showing It Illuminated with Monticello Search Light. The Secondary Aerators are in the Foreground

Slow Sand Filtration at Charlottesville, Va.

The Development and Results of Operation

By LEE H. WILLIAMSON
Consulting Engineer, Charlottesville, Va.

AN historical summary of the development of the Charlottesville Water System is essential to complete understanding of the treatment problem as is a description of the physical elements of the system.

Prior to 1925, Charlottesville's water supply was from two impounding reservoirs, located in the "Ragged" mountains about three miles southwest of the town. In elevation the reservoirs are deficient for adequate pressures in the western part of the city and at the University of Virginia.

This supply demonstrated its inadequacy as early as 1918. During the late spring, summer and early fall the water had an intensely disagreeable odor, taste and color, resulting principally from algae. Copper sulphate treatment was resorted to, but with little success.

In 1922 a pumping station was constructed on Maury Creek, a small stream flowing from the drainage area below the reservoirs, pumping back into the reservoirs for storage, a means of augmentation which not only did not improve the stored water but which was expensive due to high heads.

During the summer of 1921 the situation, both as regards inadequacy of the supply and the repellant physical characteristics of the water, became unbearable and the city officials began investigations of additional sources simultaneously with studies of treatment requirements. Surveys were made of all available sources including the Rivanna River, with the result that a gravity supply from Moorman's River was clearly demonstrated as the logical addition to the supply.

On Nov. 11, 1921, George W. Fuller of New York, Dr. M. G. Perrow of Lynchburg, Major R. Messer, Chief Engineer of the Virginia Board of Health, and myself reported unanimously in favor of a slow sand filter with preaeration, located on the Observatory Mountain, as sufficient and most economical treatment of both existing and proposed supplies. Construction was immediately begun and operation commenced in the Fall of 1922.

In 1922 and 1923, there were again acute shortages which were temporarily relieved by the installation of modern pumping equipment at Maury's Creek, so connected as to pump direct to the

new filter plant. Early in 1924 the development of the Moorman's River source was begun and the water turned into the mains on March 30, 1925.

The Completed System.—The completed system at Charlottesville, therefore, may be briefly described as follows:

The intake, consisting of simply a diversion weir, is situated in Jarman's Gap developing a total drainage area of approximately 23 sq. mi. of rough, mountainous, heavily forested land. Just below the intake is situated the grit chamber and from this an 18 in. cast iron conduit leads to the storage reservoirs near the city. This conduit is designed for pressure on the hydraulic gradient so that the only cut off is at the intake. Topography, however, allows short lengths to be drained in case of emergency repairs. The 18 in. line connects into the old 18 in. and 10 in. mains from the storage reservoirs to the filter plant, so cross connected that water may be drawn from either the reservoirs or direct from Moorman's River through either the 18 in. or 10 in. main.

With this system of connection it was necessary to prevent static pressure on the pipe line by closing valves at the filter plant or at the cross connection. Moreover, the Moorman's River conduit has a far greater capacity than present requirements and it as desired to store Moorman's River water in the reservoirs whenever possible. An open control chamber was, therefore, constructed on the hydraulic gradient so that in case of a shut down below this point all water flowed to storage in the reservoirs through the control chamber or under normal conditions the excess supply from Moorman's River, over the demand at the filter plant, flows through the control chamber to storage.

A booster station for use when drawing from the reservoirs is located near the filter plant with suitable connections to allow combined use of Moorman's River water by gravity and boosted water from the reservoir. Eighteen, 10 and 6 in. mains lead from the clear-water reservoir to the distributing system in the city.

Basic Elements in Selecting Treatment Plant.—The 1921 survey of purification requirements discovered the following elements as basic in selecting the location, type size and extent of treatment plant.

1. Two sites were available, (a) at the Impounding reservoirs and (b) on the Observatory Mountain near the University.

2. The location in elevation should be such that delivery by gravity to all parts of the city then developed or or likely to be developed in the future could be accomplished. This required the correction of notable pressure deficiencies in the western part of the city and at the university. The location was further qualified by the requirement that a supply from Moorman's River could be economically brought in by gravity, without seriously curtailing its drainage area.

3. The situation demanded a location lending its self to economical and speedy construction, with due regard for facility of operation.

1. Treatment of the existing supply required:

(a) Removal of some pollution though the water shed was municipally owned.

(b) The removal of color, taste and odor of a marked degree.

(c) The reduction of iron.

(d) The removal of very slight turbidity.

2. Treatment of the proposed new supply from Moorman's required:

(a) Removal of possible pollution. No part of the shed being owned by the city, the drainage area being 25 sq. mi., impossible of acquisition and difficult to patrol if acquired.

(b) The removal of fairly large suspended matter during the periods of flood flows.

(c) The reduction of iron.

Water from both supplies was very soft, moderately high in iron and it was evident that large volumes of fresh, clear water from Moorman's River added to the impounded supply, would vitalize the latter and greatly improve its quality.

Capacity.—1. A Pitometer survey in 1920 showed the average daily consumption as approximately 1 Mg. with the per capita consumption about normal.

2. Provision for a service supply, situated by physical necessity well away from the points of demand and the desirability of a uniform rate of filter operation dictated a large clear water reservoir. Peak rates were then secondary in the determination of the total plant capacity though they further influenced selection of a large clear well capacity as an investment economy over increased plant capacity.

Consideration of these principal, and numerous other secondary, elements, together with careful study as to the ultimate economy to be gained, led to unanimous recommendation of the slow sand type of filter with aeration, with the following thoughts uppermost as regards location, type and size.

The location at the old reservoirs was very inaccessible, served by no improved roads, and requiring a 5-mile haul for construction materials. Conversely, the observatory location was close, easily accessible, and provided many advantages and economies, both of construction and operation.

The turbidity to be removed was well within the proven ability of slow sand filters without coagulation or pre-treatment. The taste and odor being principally due to various forms of algae, were capable of adequate treatment by aeration, as was reasonable reduction of iron. The color, though high, was not beyond the capacity of the slow sand type, whose high bacterial efficiency has been undeniably demonstrated.

Simplicity of operation and consequent lower labor costs, the elimination of chemicals, lower wash water requirements, and the small size of the plant presented marked economies, in this particular case, even in the face of greater investment per unit of capacity for the slow sand filters over that for mechanical. In short, the situation was ideal for the slow sand filter with no single feature demanding mechanical filter treatment. Selection of the slow sand filter, in this instance, is as obviously correct as is the selection of the mechanical filters for the city of Richmond, for instance.

With an average demand of 1 Mgd. and clear well capacity of 1 Mg., this capacity being selected primarily in

General View of Plant, Showing Secondary Aerators in Foreground

Primary Aerators at Rear of Plant

deference to its distance from the point of demand, the desirability of a uniform operating rate and economy of Filter Construction, it seemed amply sufficient to provide 2 Mg. of Filter capacity.

Basic Data for Design.—Accordingly, the design was developed from the following basic data:

Capacity 2 Mgd.

Rate: 5 Mg. per acre per day.

115 gal. per sq. ft. per day.

08 gal. per sq. ft. per minute.

This determined the total area as .4 of an acre which was divided into 4 beds of .1 acre each.

Gravel was 12 in. deep as below.

7 in. retained by 1 in. mesh, none over 2 in.

2½ in. passing 1 in. mesh retained by ⅜ in. mesh.

2½ in. passing ⅜ in. mesh with effective size of 2 to 3 MM.

Sand was 36 in. deep as follows:

Maximum turbidity 200 p.p.m. Silica sbd.

Effection size .36 MM.

Uniformity coefficient 2.00.

The under drains were 12 in. split tile with joints laid ¾ in. open.

The area drained by each line of tile was 1,089 sq. ft. as against 1,200 sq. ft. maximum area for efficient velocity.

Friction in drainage system .09 ft.

All piping was amply large with the express purpose of conserving friction resulting in the following velocities:

Under drains, .55 ft. per sec.

Main Collector Lines, .90 ft. per sec.

Effluent Lines, .99 ft. per sec.

Troubles Operating and Their Correction.—During the first few weeks of operation the effluent had a milky color due probably, to silacious material in the sand bed. This cleared nicely, however, and at about the same time the bacterial efficiency began to pick up.

During the first summer the water from the reservoirs was at its worst due to drought and stagnation. The beds clogged rapidly and for several weeks had to be cleaned once a week. Then a red slime appeared in the clear water reservoir, having the appearance of red mud, in which small red worms bred. Experiments were at once started to determine the cause and it was found that the water was abnormally high in iron in the ferrous state which thus passed the filters in solution, was oxidized by aeration and precipitated as ferric iron in the clear well.

The remedy was the installation of aerators ahead of the filters with sufficient detention for the floc to form. The installation of this equipment relieved the clogging of the filters so that a minimum period of two weeks was maintained between scrapings when bad weather prevailed.

Enlargement.—After this correction, the effluent was excellent and in spite of the rapid installation of meters the consumption increased perceptibly. Moreover, certain industries who had previously maintained private supplies asked to be supplied from the municipal system. Since their demands totalled several hundred thousand gallons daily it became necessary to study means of increasing the filter capacity.

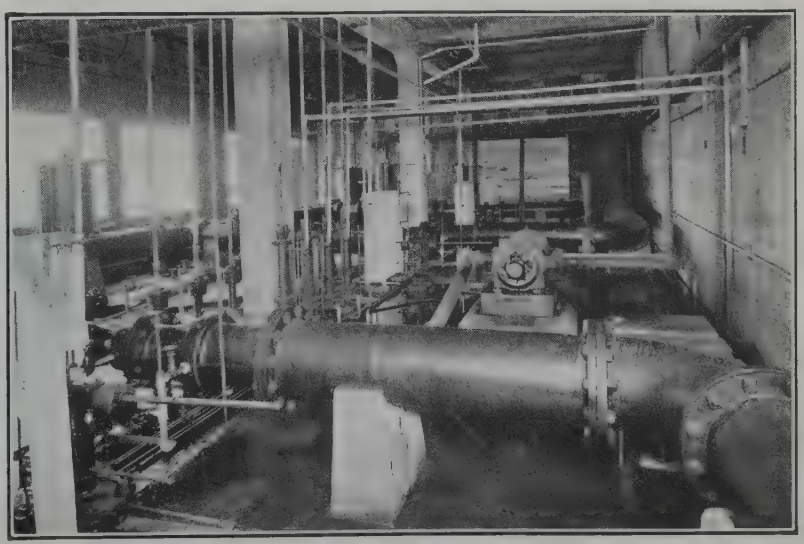
Studies were made on the basis of additional 3 Mgd. per acre rate filters with estimates of cost and found to be beyond the then financial ability of the city.

In studying the troubles encountered during early operation, an experimental filter was constructed and the results obtained indicated the possibility of using a higher rate of filtration, especially since the Moorman's River supply was assured and improvement of the raw water, even during the summer months was confidently expected. With completion of the new supply, better water was an accomplished fact, therefore the city council subsidized a series of experiments during the summer of 1925. These covered operation of a small experimental plant at various rates with studies of the water during all stages of the processes, together with studies of the water in its passage through the slow sand plant.

These experiments were made under conditions which were as adverse as can be expected, that is, when most of the water was being furnished from the storage reservoirs during an exceedingly dry season and before the Moorman's River supply had time to reach its maximum effectiveness in the improvement of the impounded supply.

The results may be summarized briefly as follows:

This water had no characteristics which would preclude an increase of rate to 10 Mg. per acre per day. Both color and turbidity ranged between 20 and 27 parts per million. In was found, however, that the water was very high



Controller Room and Pipe Gallery

in iron and the importance of preliminary aeration was clearly demonstrated. That is, it was necessary to remove as much of the iron carried in solution as possible, as otherwise it so passed the filters and was precipitated by the secondary aeration. Since preliminary aeration causes the formation of a floc the question of providing settling basins ahead of the filters was studied carefully with the idea that the load on the filters might be materially reduced by allowing the floc formed to precipitate out before the water was applied to the filters. It was found, however, that due to the nature of the floc, a period of about 15 minutes was all that was justified, since over a six hour period, only 17 per cent settled out and 65 per cent of this was settled out during the first 15 minutes.

Operating Gallery and Nichols Sand Washing Machine

The experimental filter was rigged with a pre-aerator and 15 minutes sedimentation ahead of the filter, with a secondary aerator after filtration. Operating at a 10 million gallon rate the effluent was excellent, the following tabulation showing the condition of the water at various stages of the process:

	Raw Water	First Aeration	After Filtration	Secondary Aeration
Temperature OC	23.5	23.5	23.5	23.5
Turbidity	27.0	25	5.0	5.0
Taste	Faint, Earthy	Faint, Earthy	0	0
Color (apparent)	21	20	3	3
Alkalinity	0	0	0	0
Hydroxide (OH)				
Carbonate (CO_3)	0	0	0	0
Bicarbonate (HCO_3)	18.5	17.9	18.1	17.5
(In terms of $CaCO_3$)				
Iron	0.76	0.70	.04	.04
Free Carbon Dioxide	9.30	3.7	6.1	1.6
Dissolved Oxygen	1.54	6.01	2.04	8.07
Per Cent of Saturation	17.9	69.8	23.7	93.8

Practically rates as high as 10 Mg. per day had been used only in an experimental way in this country, the most noteworthy experiment having been carried out at the Washington filter plant during 1908 to 1910, inclusive, covering a period of approximately 1½ years. These experiments were made with Potomac River water at best infinitely more turbid than the Charlottesville supply at its worst. They demonstrated that up to a rate of 10 Mg. the loss in bacterial efficiency was very small and that the cost of filtration was approximately 33 per cent lower than with a rate of 5 Mg.; also experiments at the Lawrence filters showed practically the same results, that is, that bacterial efficiency was very slightly decreased between rates of 5 and 10 Mg. per acre.

Both experiments, however, demonstrated the importance of the cleaning method used, as uniformly better results were obtained when the filters were cleaned by scraping, as is the usual method for cleaning this type of bed, than was the case when they were cleaned by the reverse flow method.

As a result, one filter was revamped to operate at the new rate of 10 Mg. per acre per day by increasing the aerator capacity ahead of the filter and providing 15 minutes sedimentation; reconstructing the drainage system by installing two 10-in. by 12-in main collectors and 6-in. split tile laterals; and installing new controller equipment of increased capacity. Thus a filter which previously had 5 Mgd. capacity new has been doubled.

The results obtained were in every respect excellent and the period between scrapings was not perceptibly shortened. The three other beds were, therefore, similarly revamped at a total cost, including the absorption of the experimental cost of $16,936.84 or $8,468.42 per Mg. of increased capacity. These figures also included the replacement of some sand and gravel lost during the change. Also the new sand was carefully selected and carefully mixed with the old sand so as to reduce the effective size to .34 mm. and to somewhat improve the uniformity coefficient. The mixing was accomplished by repeated washings with the Nichols machine.

The cost of $8,468 per 1,000,000 gal. of increase may be compared with $51,000, the estimated cost per 1,000,000 gal. of capacity of additional filters operating on a 5,000,000 gal. per acre rate.

No major troubles, either of operation or sufficiency of treatment, have been encountered since the revamped plant was put into operation in the summer of 1926 but, as will be later shown, the cost of operation has been steadily lowered. The average time between scrapings for 2½ years' operation on the 10 Mg. rate approximates 50 days, or only 10 per cent less than the period obtained when the lower rate was used. The sanitary and physical characteristics of the water have equaled in every respect the effluent obtained with the 5 Mg. per acre rate.

During summer months when the iron precipitate was heavy it was found that the installation of a coke screen over the outlet from the preliminary aeration basins relieved the filters of considerable load. These were so arranged as to be readily cleaned and cost only a few dollars each.

Cost of Operation.—In determining the cost of operation only the actual cost of treatment and purification functions are included. Similarly the fixed charges represent only actual investment in treatment and purification works. This method of cost determination is based on the theory that booster pumping and service water storage should have been provided whether or not treatment was necessary.

Thusly, the average yearly cost of water treatment, exclusive of fixed charges, has been as shown in Table I.

The high costs of 1922 and to 1924 are caused by treatment of Maury's Creek water in part and to the generally poor condition of the impounded water during the period immediately preceding completion of the Moorman's River supply. The principal element of cost being labor for scraping and washing during the summer and early fall months.

The plant has been in operation since November, 1922, and this time is log-

Table I

	'22-'23	'23-'24	'24-'25	'25-'26	'26-'27	'27-'28	'28-'29*
Aver. cost of treatment per 1,000,000 gal.	$14.28	$16.78	$7.23	$7.42	$7.90	$5.95	$5.99

*Seven months only.

ically divided into three periods: First, November, 1922 to April, 1925, during which all water came from the impounding reservoirs and Maury's Creek. This water represents the most adverse conditions and covers the starting up and shake down period. The average cost for the period was $8.94 per Mg. Rate of filtration was 5 Mg. per acre per day. Second, April, 1925, to June, 1926, during which Moorman's River water was available, causing a constant improvement of the raw water operation at the 5 Mg. per acre rate, during which water was as under the second phase, but the rate of filtration was 10 Mg. per acre per day, average cost $6.65, or 10 per cent lower than under the same conditions with a 5 Mg. rate.

The average cost over the entire period of operation is $8.94 per Mg. Over the period covering the 5 Mg. rate $11.68 per Mg. and over the 10 Mg. rate period $6.61 per Mg.

These costs include all labor, supplies, maintenance and repairs, together with light and power for washing sand.

The fixed charges over the entire period of operation average $13.53 per 1,000,000 gal., and include a sinking fund for retirement of the outstanding bonds, making a total cost at present of $20.18 per Mg. or .02018 ct. per 1,000 gal.

Acknowledgment.—The foregoing is a paper presented at the First Virginia Conference on Water Purification and Sewage Treatment, held April 25 and 26 at Richmond, Va.

Laying a Reinforced Concrete Outfall Sewer

Steps in the laying of the new San Rafael, Calif., outfall sewer are shown in the accompanying photographs. Sewage is pumped through this line from San Rafael to an outlet in San Francisco Bay. The sewer is built of centrifugally-spun reinforced-concrete pipe of 21-in. internal diameter. Pressures in the line are relatively high, sections of the pipe being reinforced to withstand a 100-ft. head. The design was based upon the estimated population in 1948.

At the End of the Pipe in Place. The Horse Moves Along on Rollers to Handle the Next Section

The pipe, which was supplied by the Bent Concrete Pipe Co., was transported from the Oakland plant of that company to San Rafael on barges. At San Rafael it was loaded on trucks and carried to various points along the line where it was unloaded. One of the illustrations shows a derrick unloading pipe from a barge to the pier. A chain hoist, suspended from a heavy steel horse, was used to lower the sections of pipe into the trench. Planks were placed across the trench beneath the hoist, and the sections were rolled over the trench. They were then picked up by the hoist and the planks were removed, allowing the pipe to be lowered into the trench. Redwood cradles were installed in the bottom of the trench to carry the pipe. The horse is provided with small wheels so that it may be moved along the trench on planks laid at the sides. For a wider trench, the wheels may be changed and the horse turned the other way.

City's Powers Defined

Authority of a city to delegate administrative powers and authority for the enforcement of health regulations was sustained in a recent decision of the Ohio Supreme Court in the case of the State ex rel. George Moock, et al, vs. the City of Cincinnati, et al, on appeal from the Court of Appeals of Hamilton County, according to Ohio Health News of June 1. This was a case growing out of denial of a permit to Moock to collect garbage after a contract had been entered into with another contractor for garbage collection and disposal. The opinion was by Judge Jones. The syllabus follows:

The city of Cincinnati advertised for and received bids and entered into a contract with a single contractor who for a consideration paid by the city, engaged to collect and remove garbage therefrom in accordance with the city's specifications. A permit was thereupon issued to the city's contractor but denied to the relator who had contracts for garbage removal with various hospitals and restaurants in the city. This garbage, consisting of animal, vegetable and other products, had a commercial value, much of which being adaptable for the feeding of swine.

Held: Neither the city ordinance nor the refusal of the city manager to issue relator a permit for the collection and removal of garbage contravened any provision of the state or federal constitution.

The Cobble Mountain Dam of Springfield, Massachusetts

Design Features of a $6,143,000 Development

By ALLEN HAZEN
Hazen, Everett & Pirnie, Civil Engineers, New York City

THE Cobble Mountain Dam is being built by the city of Springfield, Mass., as part of a development of its water supply; E. E. Lochridge as chief engineer is in charge of the entire work. H. H. Hatch is resident engineer for the construction of the dam and tunnels. Hazen & Whipple (now Hazen, Everett & Pirnie) the writer's firm has prepared the plans and has acted as consulting engineer, checking the general plans and estimates, and George A. Orrok has aided in connection with the water power and electrical development.

There have been four principal contracts:

(1) The Diversion Tunnel, let in July, 1927, to Coleman Bros., of Boston, and completed about a year later.
(2) The Main Dam, Spillway and Reservoir was let to Winston & Company of Kingston, N. Y., in July, 1928, and
(3) The Cobble Mountain Tunnel to Frazier-Davis Construction Co., of St. Louis, at the same time.
(4) The surge tank, penstock, power house, and electrical equipment to Turner Falls Power and Electric Co.

Some road and other work has been carried out by force account. The buildings over the shafts and some small parts of the work are not yet under contract. It is the intention that the whole works shall be completed by Oct. 1, 1930.

The Cobble Mountain Dam is larger and will cost more than could have been built at this time from water funds at present water rates and with a balanced budget. It is the auxiliary power that makes it financially possible now. The reservoir is very high in elevation and there was an opportunity (recognized when this source was first proposed in 1905) of developing water power when full storage became available.

After extended study in the last years, a contract was entered into with the Turners Falls Electric & Power Co., under which the company joined with the city in carrying out the development and will pay an annual rental for 30 years for the privilege of generating power.

Hydraulic Fill Type Dam.—The dam is of the hydraulic fill type, with a top width of 50 ft. a freeboard of 20 ft. above spillway level, and 13 ft. above the top of the proposed 7 ft. flashboards. The slopes are moderate and become flatter toward the bottom of the dam.

Rock fill will be a feature of the dam, a large block of this material being placed in each of the toes, rising to a total height of about 110 ft. above stream bed. Part of this rockfill was required by the original design, but after the contract was let the amount was increased by arrangement with the contractor as permitted by the specifications under the unit prices of the contract.

As a finish to the downstream toe there will be a concrete arch with a radius of 100 ft. cut securely into solid rock on each side, and resting without being cut into the rock on the bottom, with spaces for drainage underneath. This arch is 35 ft. high and from 14 to 20 ft. thick and cuts off what would otherwise have been an extreme extension of the downstream toe.

The shape of the dam is unusual. The gorge is narrow and curved. The side slopes are approximately 37° or one on 1.33. The bottom width is something like 70 ft. Under these conditions the dam has a length along its crest of only 700 ft., but is 1,505 ft. wide on the bottom measured along the thread of the stream. It is therefore more than twice as wide as long.

The height of the dam measured from the stream bed to the spillway level is 215 ft. with 7 ft. additional to the top of the proposed flashboards. To the roadway level on the top of the dam it is 235 ft. The cutoff trench in rock will extend 10 ft. or more below stream bed and is not included in these heights.

At the proposed flashboard level, elevation 952, the Cobble Mountain reservoir will have an area of 1,120 acres and will contain 22,287 million gallons of water. Of this amount 2,021 million gallons below elevation 840 are not available for power but may be drawn in case of need for water supply.

In addition to the storage in the Cobble Mountain Reservoir the Borden Brook Reservoir, constructed in the year 1909, on a tributary stream, has a capacity 2,500 million gal. Of this, under the arrangement with the Power Company, 1,500 million gal. may be drawn for power and 1,000 million gal. are held as an emergency reserve for water supply.

The volume of Cobble Mountain Dam is approximately 1,800,000 cu. yd. of which something like 400,000 cu. yd. will be rock fill and the remainder earth. All but a small part of the latter will be placed hydraulically.

Because the stream was not straight, the lower parts of the toes are turned on a regularly graduated arrangement so that the contours of the finished dam, in a general way, will be perpendicular to the sides of the valley. The total curvature of the valley is some 90° from one toe to the other and of the dam 60°, leaving 30° at a sharp bend in the stream near the upper toe. The stream bends to the left and this procedure leads to steeper slopes on the faces of the dam along the left bank of the stream and flatter slopes near the right bank.

The procedure in general was to make the desired standard slope, selected in advance, apply approximately on the side where the slope was steepest and to leave a flatter slope, or, in one case, a berm near the right bank of the stream.

The material in the damsite is mica schist rock covered to an average depth of about 4 ft., with soil.

Cut Off Trench.—To prevent seepage through seams in the rock where the core of the dam is to join the rock, a cutoff trench will be cut across the bottom and sides of the valley to a depth to be determined as the work proceeds. In the bottom of this trench will be dug narrower trenches in which concrete walls will be built extending 3 ft. above the bottom of the sider trench. One of the walls will be carried to the top on each side of the valley.

The rock below the bottom of the trench is to be drilled and grouted to cut off seams and make the rock watertight. The clay core will fill the rock trench and cover the concrete cutoff walls and make a watertight seal.

Material for Rock Fill.—The material for the rock fill is obtained from the mica schist in the immediate neighborhood of the dam. The rock rises on each side of the damsite to about 470 ft. above the stream bed or 230 ft. above the top of the dam, affording opportunities for convenient and ample quarries on both sides. The rock excavated in the course of the work, including that from the spillway, is placed in the dam as rock fill.

The mica schist, although suitable

for rock fill, will not crush to make concrete stock and there is no rock in the neighborhood of the work fit for masonry of any class. Williamsburgh granite found in some of the neighboring hills is not suitable for quarrying. There are quarries of excellent granite within 20 miles of the site but the use of this material for masonry was not seriously considered. All material for both the concrete work and the hydraulic fill must be brought from pits about a mile away.

At the dam site that soil will be sluiced into the dam and there are some limited deposits of fine grained material not far away that may be useful in construction.

The Hydraulic Fill.—The borrow pits for the hydraulic fill are glacial deposits of sand and gravel. There are fine grained layers running down, in places, to rock flour. The deposits are extensive and contain many times the required volume of material. Selection will be necessary to secure the required grain sizes. Pits carrying different grades of material will probably require to be operated simultaneously.

The contractor proposes to excavate the material in the pits with steam shovels and to carry it on standard gauge railway track to the dam where it will be dumped from tracks on the top of the rock fills, or from trestles above them, to the toes of the dam. The material will then be sluiced into the dam.

Water for sluicing is to be provided by floating pumps on the pool in the center so that the water used for building the dam will be circulated and kept separate from the water of the running stream, so as to avoid pollution of the water supply.

As the material from which the dam is to be built is sandy and gravelly in character, the problem of control of grain size is quite different from that in several other hydraulic dams recently constructed in which the percentage of clay has been high.

The specifications provide that the material in the central core shall have an effective size of about 0.01 mm., the intention being to secure a material fine enough to be, for practical purposes, watertight, but, on the other hand, coarse enough and pervious enough to permit the core material to drain sufficiently for its own consolidation.

It will be remembered that in some hydraulic dams built in the past (Hydraulic Fill Dams. Am. Soc. C. E., Vol. 83, p. 1713, 1920) the core material has been so fine that it was incapable of drainage within any reasonable length of time! and has remained permanently fluid in the center of the dam. In some cases the pressure of this fluid core has exceeded the resistance of the toes and has ruptured them during construction.

An absolute requirement of stability is therefore that the material should be sufficiently coarse grained as to drain and become solid and stable.

On the other hand, some hydraulic fill rams of sandy material have been so coarse grained and free from fine material that there has been an appreciable amount of leakage through them.

In the case of Cobble Mountain Dam approximate watertightness is desirable and necessary; to this end the core size must be regulated to insure that the completed work will be nearly watertight with only so much seepage as is necessary to insure drainage and stability.

In connection with this important subject a method of elutriation and microscopical examination has been devised to determine the character of the material being placed in the core as the work proceeds.

Diversion Tunnel.—Before beginning construction of the dam itself, it was necessary to divert the water of Little River. Work on a diversion tunnel 1,620 ft. long was started a year in advance. This tunnel is horse-shoe shaped equal to a circle 12 ft. in diameter and has a slope of 18 per 1,000. Its invert is a few feet above ordinary water level at both ends.

In connection with this tunnel there was built a cofferdam of rock fill, as a preliminary operation, so placed that it would form part of the permanent upstream toe of the dam. This was faced with enough soil to secure approximate watertightness. This cofferdam had a height of 70 ft. and was required to hold the water at a level that would produce a velocity in the tunnel to develop its capacity.

The tunnel was designed to have a capacity of 4,000 cu. ft. per second, and amount comfortable in excess of any flood that had been recorded during the 20 years that the stream had been gauged. On Nov. 3, 1927, four months after the contract had been let, there was a great flood. This was at the time of the Vermont flood. The maximum rate of discharge at the intake dam three miles below was 6,100 cu. ft. per second; and the average for 24 hours almost reached 4,000 cu. ft. per second. This was before the diversion of the stream.

The mean flow at the intake dam is about 62 mgd. It will be proportionately less at Cobble Mountain Dam or about 58 mgd.

The diversion tunnel was lined with concrete and the space back of the concrete grouted. At a convenient place a shaft 218 ft. deep was cut from the surface and a place selected upstream from it for the permanent closure and control works. In this place, after the dam is built, a concrete plug will be placed and grouted. Through this two 42 in. pipes will pass, leading to gates and guard gates in duplicate with discharging capacity of more than 1,000 cu. ft. per second, from which water may be drawn for water supply purposes or to lower the water in the dam in any emergency. Otherwise these gates will not be used.

The capacity of the outlets is such that using both tunnels water can be lowered about 3 ft. per 24 hours, the rate of drop increasing as the water falls. The reservoir could be emptied in about 30 days.

The Outlet Tunnel.—The Cobble Mountain tunnel which will be the ordinary outlet and will supply water to the power house, is 7,100 ft. long and is equivalent in area and capacity to a circle 10 ft. in diameter. It is to be concrete lined throughout and grouted. The entrance to this tunnel is 76 ft. in elevation above that of the diversion tunnel. The sill at its entrance is at elevation 830,122 ft below the top of the proposed flashboards.

This tunnel is driven through mica schist rock, similar in character to that penetrated by the diversion tunnel, and, for the most part, completely dry. A small amount of Williamsburg granite, a coarse grained local variety, was encountered. The tunnel location was selected to give ample rock cover to resist pressure, except in the lower 500 ft. which are to be steel line.

The control of water through this tunnel will be, ordinarily, by gates at the power house and otherwise by a gate at the inlet which can be used to hold the water back while the tunnel and penstocks are unwatered for inspection or repair. This gate is a Broome gate 12 ft. wide and 13 ft. high covering a carefully formed bellmouth.

A short section of tunnel upstream from this entrance is so arranged that when the water is drawn down to elevation 900 or lower, it will be possible to sink an emergency gate to cover the outer entrance and to permit the Broome gate and its seat and everything connected with it to be unwatered. The outer gate will not be provided at present, but the seat will be built so that this remedy may be applied at a future time if it should prove necessary.

Power Development.—At the lower end of the tunnel a steel pipe lining will be used extending to a point where the rock above is approximately at the elevation of high water in the reservoir. At its lower end this pipe is connected to a surge tank and then to three penstocks. These go down a steep declivity to the power house which is built at the end of the small reservoir formed by the intake dam. From the intake dam water is drawn to the filters as needed and the rest of the flow spills down the stream.

The flow line of the Cobble Mountain Reservoir, at the flashboard level, will be 456 ft. above the present flow line of the intake reservoir. This possible head on the wheels will be reduced by drawdown in Cobble Mountain Reservoir and by friction in the tunnel and penstocks. The working head will vary from about 450 ft. down to about 350 ft, with a possible extreme minimum of 330 ft.

It will probably average in the neighborhood of 400 ft.

The power house is provided with a capacity to use water at a rate equal to ten times the mean flow of the stream. It will thus operate on a 10 per cent load factor. This relatively large development is provided with reference to using this plant to meet peak loads.

Daily power peaks will be met by drawing the water required for water supply during those hours of the day when the power will be most useful and the city has storage to carry through the day from water so drawn.

The city at present uses a little less than 15 mgd. and the mean flow of the stream is 62 mgd. The difference, 47 mgd., may be stored and drawn on any days or hours when it will be most valuable during the whole course of the year. This condition will permit a large part of the power to be drawn when water power stations, operated by the company on other streams, are short of water and to meet emergency and peak loads of any kind.

The Spillway.—The spillway of a dam of this character is most important. When the work was started the largest flood on record measured at the intake dam was 4,410 cu. ft. per second. After the work was started there was a larger flood as noted above, with a maximum of 6,100 cu. ft. per second.

From a study of the records of flow of this particular stream, the indications are that the greatest average flow for 24 hours to be expected once in a hundred years would be 4,850 cu. ft. per second.

In view of the character of the occupation of the valley below the greatest precautions were warranted against overtopping of the dam, and it was decided to lay out a spillway channel with a capacity of 20,000 cu. ft. per second, equal to more than 436 cu. ft. per second per square mile of tributary area. This is equal to five times the record 24-hour average flood of the record period.

There was an excellent natural site for the spillway through a notch in the mica schist rock on the opposite side of Cobble Mountain from the dam.

Using this notch required a considerable amount of rock excavation but the rock obtained could be placed and is being placed in the dam.

The crest of the spillway was laid out 135 ft. long. The channel from it drops 15 and narrows as a bellmouth to a width of 50 ft. and then extends with a grade of 1 per cent for a total distance of about 700 feet from the entrance, at which point the rock falls off abruptly on a slope of approximately 31° to the river bed. The total vertical drop is about 255 ft. The flow will reach the river about 3,000 ft. downstream from the lower toe of the dam.

With a well-rounded crest and a gradual approach, the spillway should carry 20,000 cu. ft. a second with about thirteen ft. head.

The water level in the reservoir would then be at elevation 958, at which level it would still be 7 ft. below the top of the dam.

The spillway channel was calculated so that at each point, with an assumed water level, which would pass 20,000 cu. ft. per second, the water level, plus the velocity head, plus an estimate for friction from the entrance to that point would equal the assumed reservoir level i. e., 958.

The allowance for friction not being capable of being estimated closely, a liberal and perhaps excessive allowance was made for it, amounting to 1 per cent of the total distance from the entrance to each point of calculation. Water velocities in the neighborhood of 20 ft. per second were estimated.

The estimated cost of the Cobble Mountain dam and reservoir and the power house and of all that goes with it, but not including the Borden Brook Reservoir built in 1909 nor the land, most of which has been previously purchased, nor other parts of the water supply system, is $6,143,000.

Contracts have been let covering the major parts of the work and a substantial part of the work has been done. Some things remain to be arranged. There is every indication at present that the work will be completed for a sum materially less than the estimated cost.

Acknowledgment.—The foregoing is an abstract of a paper presented at the 49th annual convention of the American Water Works Association.

Relation of Direct Bact. Coli and Bact. Aerogenes Counts Obtained with Cyanide-Citrate Agar, to Sources of Pollution

By FRED C. TONNEY AND RALPH E. NOBLE

Bureau of Laboratories and Research Department of Health, Chicago

Recently developed direct plating methods of counting coli-aerogenes organisms have made possible the routine determination of separate Bact. coli and Bact. aerogenes indices in 48 hours by the same process in which the combined Bact. coli-aerogenes index is obtained.

Our experience with such a method, employing cyanide-citrate agar as a different medium, led us to consider the possibility that additional data of primary sanitary significance bearing directly on fecal pollution might be available for practical use, in the individual Bact. coli and individual Bact. aerogenes counts, and also in their numerical relation to each other. It was thought that possibly data derived from separate Bact. coli and Bact. aerogenes determinations might offer a better basis for discriminating sanitary judgment of true fecal pollution than can be arrived at from the combined coli-aerogenes index, which includes a variable number of organisms not strictly of fecal origin.

Confirmation studies of the distinctive type colonies on the medium, designated as "Probable Bact. Coli" and "Probable Bact. Aerogenes," indicated a high degree of agreement between the characteristic appearance of the colonies and the recognized differential tests for these two organisms, viz: the methyl red Vogee-Proskauer reaction, the ferric ammonium citrate and sodium citrate tests and the colony characteristics on eosin-methylene blue plates.

The phase of the investigation here reported was directed toward the primary sources from which these organisms find their way into water supplies. It consisted of a quantitative study of the Bact. coli and Bact. aerogenes content of (1) human and animal feces as the primary source of Bact. coli; (2) soils, decayed vegetation and grains as a primary source of Bact. aerogenes, and (3) sewage as a composite mixture derived from the two primary sources named.

A brief summary of the relationship found is given in Table I.

The data indicate that numerically Bact. coli is the organism primarily characteristic of feces; that Bact. aerogenes, although occurring in feces, is numerically insignificant in the aggregate; that Bact. aerogenes is primarily characteristic of coli and vegetation; that the ratio of Bact. coli to Bact. aerogenes in sewage in the Chicago district points to fecal sources and soil sources as contributing in nearly equal proportions to the total number of coli-aerogenes organisms present.

Acknowledgment.—The above is an abstract of a paper presented at the 49th annual convention of the American Water Works Association.

Table I.—Relationship of Bact. Coli and Bact. Aerogenes Colonies from Fecal and Non-Fecal Sources

The Importance of Regional Planning

The Need for the Regional Planning Association; Its Problems

By J. R. FAIRMAN
Manager Southeastern Offices, Portland Cement Association

NEARLY everyone has in mind some city improvement he thinks would be of great benefit; one man wants the street on which he lives paved, another wants a park established, still another believes a certain street should be widened, this man would like to install a new system of traffic lights, and so on. With all this disunified thinking and planning, I sometimes am forced to wonder how many communities have achieved any semblance of order.

Almost overnight the automobile has changed our mode of living. Through the ability of the individual to get easily about the country, a new standard of living and of education has developed. A city is no longer self-contained; its prosperity and development depend to a large degree upon the prosperity of an entire region.

Importance of Suburban Communities.—Chief among the several problems confronting the modern city is the provision of adequate facilities for motor traffic. Suburban districts have long existed, but never in all history has their relationship to the city been of such importance and concern as at present. Suburban areas are expanding, cities and their suburbs are now growing together; and the automobile is bringing remote communities nearer to the city. Haphazard growth must be halted, in the face of such tendencies, if a full measure of community efficiency, comfort and beauty is to be attained.

Progressive, populous communities in many parts of the country have adopted regional planning as the medium best adapted to handling this perplexing problem. City planning is not broad enough; our communities are bursting out at the sides. There are greater opportunities in adjacent areas than in the city proper. The picture puzzle of community needs must be solved by trained minds, made available through some such agency as a regional planning commission, whose duties include the analysis of all such factors as population increase, suburban growth, vehicle registration, both present and future, expected industrial development, residential trends, zoning, finances available for improvements and many other items. Equipped with facts, this commission will make recomendations and cooperate with other existing agencies to the end that a regional plan of a comprehensive, forward-looking nature will be carried out.

I had realized, of course, that city populations in Florida were increasing, but I must admit I was somewhat startled to learn that since 1925 the population of Jacksonville has increased by 60 per cent; Tampa, by 85 per cent; Miami, by 128 per cent; and St. Augustine, by 80 per cent.

These growths are phenomenal, yet there is every indication that Florida cities are to continue attracting citizens at a high rate. Your cities still have time to convert themselves into communities that are modern in the fullest meaning of the word.

Unfortunately, regional planning did not exist when most of our cities were created. Without knowledge of the changes to be wrought by the automobile, or of the great size to which cities would grow, the early planners neglected to provide for logical and directed growth. Streets, for instance, were rarely of more than the age old four-rod width. Of all the American cities, with the exception of the nation's capital, the only one I can call to mind that made any early attempt at planning for the future was Detroit.

Experience of Detroit.—That city was destroyed by fire nearly one and a quarter centuries ago, as were so many early communities. Afterwards, a prominent Detroit citizen, Judge Woodward, and Governor Hull of Michigan, were responsible for laying out a new Detroit, a Detroit with thoroughfares of three widths. Streets of minor importance were made 60 ft. wide, secondary radial arteries, 120 ft. and major arteries, 200 ft. This was a marvelous thing, but sadly, later generations, unable to visualize the Detroit of the futre, encroached on these wide rights-of-way and today only a few remnants are in service.

Loss of these broad streets, which would so well have served today's traffic, was a costly thing for Detroit. That city is still paying for it through traffic congestion and through time and money consuming condemnation proceedings and other means to gain back a portion of that space once devoted to streets. All of this could have been avoided through adherence to the original far-seeing plan.

View of Roosevelt Road in Cook County, Illinois

But what Detroit lacks today in extra wide downtown streets, she has made up for in suburban development. A master plan has been adopted that serves as an object lesson for Florida municipalities. This master plan embraces a comprehensive system of wide roads, many of which are already completed, thereby permitting fluidity of present traffic. This plan is a continuing plan; each year definite progress is made toward lengthening the mileage of pavements, none of which is less than 40 ft. wide. In the Detroit region they have a battle cry—"Acquire wider rights-of-way today!" To this might well be added the phrase "for tomorrow they will cost more money."

The master plan predetermines the position of the transportation avenues which form the skeleton of the street system in the outer areas. It provides for superhighways, 204 ft. wide, at three-mile intervals, designed to offer local and through roadways for motor

Waukegan Road in Cook County, Illinois, Widened to 40 Ft.

traffic on each side of a center zone reserved for rapid transit service, or future widening or other development. Intermediate roads 120 ft. wide are located at mile intervals on section lines. A supplementary system of major thoroughfares 120 ft. wide is established at intervals of approximately three-fourths of a mile within the area of present development.

That is indeed an ambitious plan; yet it is already well under way. Words can scarcely convey a true picture of what Detroit and Wayne county have done; I would suggest that if any of you have the opportunity, you spend a week-end in and near the Motor City.

The Regional Planning Association.—Many factors enter into city expansion and development. These are of such a serious nature as to require scientific and thorough study of all the principles involved in order that tax payers may be provided with the facilities and conveniences which are their just due. You will grant, I am sure, that little would be accomplished without some central fact-collecting body to study all the proposals, pushing through to completion those best fitted to the community welfare.

Stated in its simplest form, the purpose of the regional planning association is to make an intensive study of all the factors entering into the community's growth and welfare, so the greatest convenience and comfort may be obtained for the tax dollar. The costly experience of a certain Illinois community must be avoided. There, a splendid 40 ft. pavement was built out into the country, but unfortunately it ended abruptly in a corn field and was of no use whatsoever to the community for a couple of years.

Transportation.—Chief among the problems facing all communities is that of transport. Adequate transport service not only means that railroads and street railways must be well connected, but also that highways and streets shall form a perfect network of main arteries and secondary roads. Street layouts marked by dead-ends, jogs, narrow widths, poor pavement and a total lack of coordination, must be avoided. Industrial traffic must be studied so heavy trucks can be accommodated without hindrance to passenger vehicle traffic. On the other hand, high speed thoroughfares must be constructed so passenger cars will not be unnecessarily delayed by trucks. Through traffic should also be taken care of. The idea that motorists whose destinations are far away should be directed through the downtown section of cities is now old fashioned. By-pass routes must be provided so this traffic can continue on its way unhampered, and what is more important, with no inconvenience to the home community.

Water and Sewage.—Water and sewage must be given careful attention in the makeup of the up-to-date community. The automobile has made it possible for the downtown worker to establish his home in the outer precincts of the city or even out in the country. Sanitation must be carried to him. Villages and suburban centers must cooperate, for in this cooperation the citizen is given better service with complete safety and at lower cost. Without planning, it is too easy for much needed projects to be neglected and to become political footballs. In the Passaic Valley of New Jersey, for example, a trunk sewer now serves a thickly populated region embracing quite a number of separate municipalities. It was proposed to establish this sewer more than twenty years ago, but endless litigation and negotiation was necessary before it became a reality. All this delay was at the public's expense.

Utilities.—Even in the matter of public utilities, the way is open for the city to accomplish a great deal through early planning. Electricity and gas reach out everywhere. Electric lines and conduits through town and country possibly may conflict with the highways. Early planning of highway improvements will give the utility firms an opportunity to develop their facilities for the best interests of the public and also it will aid them in preventing a later conflict for rights-of-way.

Political Obstacles.—One of the greatest achievements open to the regional planning association is the overcoming of problems which I shall call political for want of a better term. The boundaries of governmental units in any region are irregular and often without reason—illogical results of haphazard growth. Areas of municipalities are often either so restricted as to hamper growth, or so extended as to impose some undue burden on the well occupied districts. In the case of the region of

Mona Ave. and Hutchinson River Parkway Grade Separation in Westchester County, New York

Chicago, there are almost exactly 1,000 separate taxing bodies within 50 miles of the downtown section of that city. You are of course not bothered to that degree in Florida. Nevertheless, real progress depends upon the complete cooperation of all governmental units involved.

The Chicago Region.—Here are some of the chief aims of the Chicago Regional Planning Association:

Adequate pavements on every main highway in the region of Chicago, continuous across state, county and city, and their boundary lines.

Adequate paved street connections with the paved highways.

All bridges wide enough for future pavement widening or built so that they may be widened.

Grade separations at all dangerous railway crossings.

Grade separations at the most important highway intersections.

Uniform traffic regulations in every county, city and village region.

Every highway marked only with official, legible signs of cautions and direction.

Every main highway adequately lighted at night.

Trees planted and maintained along every highway for the comfort and delight of all highway users.

Attractive public comfort stations properly located along all important highways.

Chicago, large in itself, is the center of a populous territory and the regional planning problems there are intensified. Nevertheless, the smaller city is faced with the same troubles and identical improvements must come sooner or later.

Planning for a Smaller Community.—Let us look for a moment at the program of a small community—Riverside, Calif., with a population of about 25,000. Riverside has already made remarkable progress and the improvements mapped out for that city bid fair to make it one of the most attractive in the country insofar as appearance, comfort and ease of traffic movement are concerned. Climate is, of course, another matter.

Capitol Drive, 60 Ft. Wide, Milwaukee, Wis.

The steps being taken in Riverside are:

1. Regulation to secure maximum capacity of existing space, including elimination of auto parking, prohibition of obstructive turns at particularly busy intersections, ranking of vehicles, use of most effective signaling, curtailment of unnecessary movements and so forth.

2. Improvement of existing street plan, including elimination of jogs and dead-end traffic streets, creation of distributor and by-pass streets for the business district and improvement of radial and inter-district thoroughfares of the major street plan.

3. Extension of a regional major street plan to cover the whole district for several miles in each direction outside the city limits, and completion of a boulevard and parkway system plan supplementing it.

4. Provision for the readjustment and extension of railroad lines, with gradual elimination of grade-crossings.

Florida Cities.—Regional planning is, of course, quite new and I am much pleased that some of your Florida cities are giving serious consideration to this planning movement. If anything, your problems are more intense than they are in any other part of the country. Florida is growing rapidly, you have a marvelous tourist business, you have an established clientele of winter pleasure seekers. Naturally cities in a state so blessed, will grow faster than the average American city.

Jacksonville, I understand, has a city planner, who is not only confronted with traffic and expansion problems within Jacksonville, but is also obliged to consider the whole of Duval county. Obviously, he must take into consideration the principal arteries of travel into Jacksonville, such as State Road No. 1 from the west and No. 4 from the north and to the south, as well as others.

Travel in that city at present across the St. John's River is over one bridge and by one ferry. Clearly, any comprehensive municipal plan must take into consideration the ever increasing need for additional trans-river transportation facilities. New bridges should be located so as to relieve as much of the intra-city traffic as possible, and provide easy crossing of the St. John's River for through traffic as well as local traffic.

Jacksonville's situation definitely indicates why the modern city must extend its city planning to planning in which the whole region is considered. Tampa presents a problem of similar character. Broad thoroughfares leading into the city must be so located and built as to conform to a plan of the

Four Lane, Hudson River Parkway, Westchester County, New York

greatest possible utility to the city itself.

Miami has already made noteworthy progress through the building of wide arteries. Biscayne Boulevard, 220 ft. wide over an eight-block length, is an excellent example of the type of facility that must be installed if there is ever to be room for the prolific automobile. One of the great difficulties of this modern age is finding a place to park. From this standpoint Biscayne Boulevard is something of a motorists' heaven, for 2,000 cars may be parked along it without hampering travel. You can well imagine what impression Biscayne Boulevard will make on the tourist or home seeker. That latter important individual, particularly will feel, "Here is a city that is progressive, a city that is attempting to make things comfortable for its citizens. I will make my home here."

If your city is smaller than Tampa, Miami and Jacksonville, that does not mean you are freed from the responsibility of regional planning. In fact, it is just as important in the small city as in the large, and frequently more important, for the small community must have something to offer in place of large hotels, office buildings and theatres. Here in St. Augustine there is every indication that before long an improved through route will be needed. Because there is so much of historic interest in this community and so much that must be preserved to the nation for all time, it is highly improbable that the widening of thoroughfares through the old section of the city will be contemplated. However, the ever increasing traffic through the city will shortly demand a broad pavement acting in the nature of a by-pass so the present narrow and winding route may be relieved.

Blue Mound Road, 60 Ft. Wide, Milwaukee County, Wisconsin

Separation of Traffic Arteries.—Superhighways, roads of more than the usual width, elevated street intersections, railroad grade separations, and pedestrian tunnels are a few of the modern facilities forcing themselves into the up-to-date traffic picture. These improvements are no longer regarded with doubt, for cities in many parts of the country have through experimentation proved that they are absolutely practical. One great elevated street separation in Lincoln Park, Chicago, has increased the traffic capacity of Lincoln Park thoroughfares by 300 per cent. That is to say, this one structure has given, in effect, three additional roads. These elevated intersections, wherein one street or road passes over the other, permitting traffic to flow in all four directions continuously and safely, must be placed at strategic points.

The benefits of railroad grade separations are obvious. Surveying accident records, it appears that nothing will eliminate accidents at grade crossings except construction of a bridge over or a tunnel under the tracks so motor and train traffic never will meet.

Need for Wide Thoroughfares.—Wide streets and wide rural roads must be included in every adequate transportation scheme. Thirty years ago the average motor vehicle required a lane only 7 or 8 ft. wide in which to move with ease and safety. Since then the average vehicle width has been increased, the maximum generally being 8 ft. Ordinary speed of travel has doubled or tripled and vehicles have grown tremendously in numbers. Street and highway authorities are agreed that, in metropolitan areas at least, the lane of pavement for moving traffic should 10 ft. wide; for parking parallel to the curb it should be 8 ft.; and for diagonal parking, 18 ft. in width, the latter dimension convertible into an added lane for moving traffic with parallel parking. These lane widths are considered minimum for safety and free movement of traffic under all conditions of light, darkness, rain or dry weather. They are also considered maximum, because a slightly wider lane invites the crowding in of another car, which is dangerous.

The superhighway may roughly be defined as a roadway of ample width for the accommodation of four or more lanes of traffic. Of great importance, is the placement of these

superhighways. They should be so located that the largest number of motorists will be benefited. Superhighways should be built first where they are most needed. Naturally the only way to determine where wide arteries should be built, is by means of a traffic survey. Traffic as it seems and as it actually is, often are two different things. For instance, a traffic count taken at Buffalo, N. Y., revealed figures that surprised even those fairly conversant with that city's traffic problem. More than 50,000,000 vehicle movements across the city line took place in 1927, a daily average movement of over 138,000 vehicles! Other surveys conducted by cities and states throughout the country have in many instances revealed that heavier traffic exists on certain roads than was expected.

Here again there is a definite need for the regional planning association. Varying interests in the community, the ability to pay for additional civic improvements and anticipated future community growth must be considered in location of such thoroughfare.

Acquiring Rights-of-Way.—Another paramount issue is the matter of rights-of-way. The procedure followed by the superhighway commission of Macomb and Wayne and Oakland and Wayne counties, surrounding Detroit, indicates what must be done in all communities expecting to grow. This commission, in anticipation of future highway needs, is acquiring rights-of-way of varying widths up to 200 ft. The width of the original road surfaces has been predetermined. In the future when additional road surface is needed, pavements will be laid without any delay whatsoever.

The regulation of the use of private property by a public agency, through zoning has become well established as a function of government. But what is done by zoning bodies and engineers in the way of placing restriction upon the free use of private property must have a lasting effect upon the community whether the work is well or poorly done—whether the ordinance is well or poorly administered. It is desirable, of course, that the results be the best obtainable.

Through the medium of the regional planning association, and the thorough studies which can be made by such an organization, proper city zoning may be accomplished.

After all, the metropolitan community can be regarded as a child; it must be properly nourished and its development must be properly guided. Clearly, there should be some ruling, guiding hand to correlate the manifold activities of government along this line.

Proper Planning Pays Dividends.—There is no governmental agency authorized or qualified to do the work for a city and its environs too. Whatever is to be accomplished must come through the activities of the citezens themselves. The body necessary to do such work must be non-political, for it must carry on a unified plan through year after year of changing governmental officials. The regional planning associations built up by Chicago, Buffalo, St. Louis and many other cities, have demonstrated the need for such progressive scientific bodies. The modern city is growing more complex. Changes in the organization of the city must come about if it is to keep pace with the changes in our living standards. More is expected of the community than ever before; pure water must always be on hand; streets must be smoothly paved; the schools must be excellent; the parks must be spacious and clean; sewage disposal must be never failing; protection from fire must always be at hand.

All these things cost money, and their costs are personified in the taxes collected by the various governing bodies. If the citizen can be made to realize that the conveniences furnished by his government are in reality part of his personal wealth, that actually through many improvements he receives more than he pays for, he will become more willing to support the improvements which modern conditions require.

All taxpayers are naturally interested in economy; they must be assured that their money is being properly expended. They are demanding that the principles of private business be adopted in conduct of the business of government. The business that is permitted to run itself cannot be as profitable as one that is carefully and thoughtfully directed. Through the medium of a regional planning association the community's growth and future are safeguarded, its funds are most effectively invested in dividend-paying improvements and its energy is most efficiently employed.

Acknowledgment.—The foregoing paper was presented on June 27 before the Florida League of Municipalities at St. Augustine, Fla.

25 Cities Plan Airports

Three New York cities are planning airports or contemplating improvements of existing airports, the Commerce Department announces in making public a list of twenty-five cities in the country where airports are planned. The announcement said that improvements of the Watertown airport are contemplated, while new airports are planned at Middletown and Tupper Lake. Other airports are planned in the following cities:

Eureka, Cal.; Pensacola, Fla.; Brunswick and Montezuma, Ga.; Corbin and Hopkinsville, Ky.; Natchitoches, La.; Calais and Camden, Me.; Winchenden, Mass.; Lake Odessa, Mich.; Benson, Minn.; Pinewald, N. J.; Ephraim, Wis.; Bismarck and Finley, N. D.; Cambridge and Highland, Ohio; Redmond, Ore.; Providence, R. I.; Texon, Texas and Culpeper, Va.

Municipal Yacht Harbors

A survey completed recently by Richard R. Blythe of New York as representative of the National Association of Engine and Boat Manufacturers, shows that a public yacht basin has been a profitable investment for cities. The survey included personal investigations in eleven cities from Boston to Corpus Christi, Tex., as well as reports from a number of other cities.

Miami, which netted $12,435 in nine months out of total income of $14,181, is planning to increase its municipal yacht facilities by 200 per cent.

Detroit, one of the first cities to establish motor-boat wells, netted $9,831 in 1927, but its wells were burned last year and are being replaced with steel and concrete structures to house 288 boats. The city expects an annual profit of $30,000 out of a $250,000 investment. Charges range from $75 to $125 a year, depending on the size of the boat.

Chicago, which has done a great deal for boat owners with anchorages in Lincoln and Jackson parks, is planning to do considerably more, building breakwaters and forming canals as part of its lake front development program. A 42-ft. cruiser pays $30 a year for dockage there; a 60-ft. pays $50.

New York has more pleasure boats and fewer facilities than any waterfront city in the country. The only public accommodations are on the Jersey side of the Hudson, in Palisades Interstate Park. Much conversation is being expended in an effort to get something done for the boat owners there.

Boston is in the same fix as to public facilities, although many private clubs have accessible anchorages.

Down in Houston, Tex., a man bought a speed boat for his sons, discovered there were no adequate facilities, bought a piece of property and developed it, and provided stalls for thirty-five boats. His land cost $20,000 and is now worth some $60,000, according to Blythe's report. Houston is planning a municipal development, as are Galveston, and Corpus Christi on the Gulf, Memphis on the Mississippi and Charleston, S. C.

New York City Increases Pay of Its Employees.—Salary increases to 28,000 employees of New York City who are now receiving $3,640 a year or less, were voted June 27 by the Board of Estimate, to become effective on Sept. 1. Though approximately 10,000 members of the Street Cleaning Department will share the benefits of this action, the greater number of its beneficiaries are enrolled in that class commonly known as white collar workers. The aggregate cost to the city of these increases, it is estimated, will be from $4,250,000 to $4,276,000 yearly.

Sewage Plants and Mosquito Propagation

Relation of Plant Operation to Mosquito Breeding

By JOHN P. PETERSON

Superintendent, The Bergen County Mosquito Extermination Commission, Hackensack, N. J.

IN Bergen County we have closely watched the growth of the county from a cluster of small hamlets to a county of some 350,000 population, and during the growth we have noticed considerable changes in the method of sewage disposal, and the changes were all for the best. While these modern changes were being made in respect to sewage treatment plants, we, of the mosquito control forces, were busy draining swamps, ditching and diking the salt marshes and oiling the city dumps, and paying little attention to areas in the vicinity of the Imhoff tanks. During the past few years we reached a point in our drainage program where we felt we should be getting good results from our labors, only to find that the streams and ponds which we thought to be pure and wholesome were actually breeding large numbers of mosquitoes. We not only found the streams and ponds breeding but also the smaller pools and pockets adjacent to the streams. Close inspections in every case brought out the fact that the water was receiving effluent from a disposal plant.

We also found that some streams had an accumulation of from 6 in. to 8 in. of silt deposited on the bed of the water course. This tended to raise the flow line and consequently, after a heavy rain, would flood the banks and leave pools and pockets of sewage charged water in the swamps alongside of the streams, which in turn would become an ideal breeding place for the Culex Pipien.

These facts were reported to the Commissioners, and they suggested that a survey be made to determine the relation of sewage treatment plant operations with the propagation of mosquitoes.

What the Survey Showed.—The survey brought out the fact that of 42 plants in Bergen County 18 were directly responsible for mosquito breeding in waters receiving effluent from disposal plants, that nine were indirectly responsible and that 14 were not causing breeding and in one case no effort was made to clarify the sewage. This last mentioned case consists of the waste of some 200 employees of a railroad shop, plus the run-off of a large laundry. This untreated sewage runs into an open ditch some 8,000 ft. in length and finds its way to the Hackensack River. This case, however, has no bearing on the subject, as it is direct pollution.

In making our survey we covered each plant in the county and made brief notes as to conditions found. I will not attempt to discuss the findings in each case but will mention a few to give you an idea of what we have to contend with in our efforts to control mosquito breeding.

Conditions at Some of the Plants.—First: The sewage treatment plant in town A was built in 1926. It is composed of digestion and sprinkler systems sufficient in size to handle 25,800 people. The present population using the plant is 5,260. The outlet for the plant is a drainage ditch, 2½ miles in length, with no dry season flow.

At present the plant discharges effluent that is cloudy and holds large amounts of solids in suspension. In 12 months, 18 in. of solids were deposited on the bottom of the drainage ditch. This placed the drainage factor of the ditch at a minimum, and large areas, heretofore dry, were flooded with polluted water. A grave mosquito problem presented itself and the burdens of the expense placed on the mosquito commission. The seven acres of flooded meadow, in this case, supplied mosquitoes for five surrounding communities.

Second: In the town of N there is located a small lake of some 10 or 15 acres, and prior to 1925 was considered an ideal swimming pool, a place where one could linger and fish. Our inspectors, however, made weekly inspections of this lake and not until 1926 did they report any mosquito breeding. Breeding was reported throughout the season and an effort to control breeding here with oil was futile due to the width of the lake and the heavy growth of water plants. In 1927, heavy breeding was reported during the months of July and August, and we had the same trouble as the year previous. In 1928, conditions became so bad that it was necessary to open the sluice gate and drain the lake, with the result that the water which furnishes power for the mill at the lower end of the lake was unable to function for a period of three days. Due to this loss it was impracticable to ask the owner to again open the sluice when breeding re-occurred.

The pollution of this lake is caused by a sewage treatment plant located about 1½ miles further upstream.

Third: This plant was constructed in 1916 and we found little to complain of until 1926 when, due to overtaxing, heavy material was discharged from the drying beds direct to the open meadow, and in 1927, this condition became worse. In 1928 some 3 or 4 acres of meadow land was affected and heavy breeding was found throughout this area. This condition is in close proximity to several towns with a population of approximately 16,000.

Fourth: This plant is located some 1,500 ft. from the water and the effluent is run from the tanks to the creek through pipes. Due to leaks in the joints of the pipes considerable sewage is deposited over the surface of the meadow and with each high tide it is spread in all directions through a heavy growth of cat-tails. Heavy breeding is found within a 1,000 ft. of the pipe, while further away little or no breeding is found in the tide water that covers the meadows. This plant is near three large towns and we have received numerous complaints due to the prevalence of mosquitoes.

In bringing this paper to a close, I wish to demonstrate that the effluent from a plant that is overtaxed or improperly operated is a factor in mosquito control, in so far as it not only stimulates the breeding of mosquitoes in the water that receives the effluent but also tends to create new breeding places by clogging the streams with sediments and causing the water to flood adjacent lowlands.

Acknowledgment.—The foregoing is an abstract of a paper presented at the recent meeting of the New Jersey Sewage Works Association.

Treatment of Laundry Wastes

The original subsidence tank at the waste treatment plant of a laundry in Maryland was converted into an agitation and subsidence tank by placing an ordinary wagon wheel at the base of a vertical shaft so that the contents of the tank can be thoroughly stirred as the chemicals are applied to the raw method. From this tank the effluent passes to a secondary subsidence tank, thence to a cinder and gravel oxidizing bed, the overflow from which passes through a sand filter. The laundry operates three days a week and discharges approximately 1,000 gal. per hour. Studies at this plant were begun in 1927 by the Bureau of Sanitary Engineering of the Maryland State Department of Health, and were continued in 1928. According to the recently issued report of Abel Wolman, Chief Engineer of the bureau, experiments were carried on with different coagulants and at the end of the year the most satisfactory results were obtained with 7.2 grains per gallon of chlorinated copperas and 15 grains per gallon of sulphuric acid. This treatment produced a clear effluent, of a slightly greenish color, from the sand filter.

Reduction of Carbonate Hardness by Lime Softening

Results of the Excess Lime Recarbonation Process

By CHARLES P. HOOVER and JAMES M. MONTGOMERY

Chemist in Charge, Water Softening and Purification Works, Columbus, O.; Manager, Water Works, Piqua, O.

THE purpose of this paper is to describe a process by which the carbonate hardness can be reduced to the solubility limit of calcium carbonate and magnesium hydroxide.

Chemical handbooks usually record the solubility of calcium carbonate as being 13 to 20 parts per million and magnesium hydrate as being 1 part per million or, in terms of calcium carbonate, 1.7 parts per million.

These figures represent the limit to which carbonate hardness can be reduced by lime softening. In actual practical use of this process, results as low as 17 parts per million have been obtained.

The Excess Lime Recarbonation Process.—The process to be described has been in continuous use at Piqua since June, 1927, and has since been used at Columbus, Marion, Delaware, Greenville, Newark and other Ohio plants.

If lime is added in sufficient excess it will not only convert the bi-carbonates to normal carbonates, but will precipitate practically all of the magnesium salts as magnesium hydroxide. The excess lime required to precipitate the magnesium compounds to the lowest possible limit has been found at Columbus and Piqua to be that amount necessary to give the water a caustic alkalinity of approximately 40 parts per million. The caustic alkalinity or excess lime is determined on samples of water taken at the outlets of the mixing tanks. Lime softening reactions may not be entirely completed upon leaving the mixing basins and as these reactions depend largely on the temperature, the sufficiency of the dosage is more accurately determined if the samples are heated to 50° C. and filtered through paper filters before the titration for excess lime is made. After heating and filtering the sample a 100 c.c. portion is titrated with N/50 sulphuric acid, using phenolphthalein as an indicator. When the end point is reached, methyl orange indicator is added and the titration continued to the end point. Twice the alkalinity to phenolphthalein should exceed the methyl orange alkalinity by approximately 40.

The following is a typical analysis of water from the mixing tanks at Columbus and Piqua:

Total alkalinity	68
Phenolphthalein alkalinity	51
Caustic alkalinity	36

After the bulk of the precipitate has settled out, the water should be recarbonated. Montgomery* discovered that recarbonation should be continued to the point where the total alkalinity minus two times the phenolphthalein alkalinity equals approximately 5. For example:

Total alkalinity	53
Phenolphthalein alkalinity	24
Caustic alkalinity	0

If water softened and recarbonated as described is allowed a long reaction period as at the Marion, Ohio, plant, or if it is filtered through conventional type sand filters the alkalinity will drop to about the solubility limit. Recarbonated water of the above analysis filtered through the Columbus filters showed the following results:

Total alkalinity	22
Phenol alkalinity	11
Caustic alkalinity	0

The average results at Piqua in May, 1929, are shown in Table I.

The Advantage of the Process.—(1) Carbonate hardness can be reduced to practically the theoretical limit.

(2) Consistent reduction in hardness can be made irrespective of temperature.

(3) Cost of softening is reduced.

(4) Carbon-dioxide content of softened water reduced; and,

(5) Removal of magnesium according to Graf† eliminates much of the scum left in pans and bath tubs by the reaction of the water with soap.

Effect of Temperature on Process.—The reduction in carbonate hardness by this process is much less influenced by the temperature of the water than by the conventional type softening process. The following are typical results obtained at Piqua, while treating cold river water in freezing weather and relatively warm river water in the summer time (see Table II):

Cost of This Process of Removing Hardness as Compared to Removing It with Soda-Ash or by Zeolite Treatment.—During the 19 years of operation of the Columbus plant before recarbonation, the alkalinity of the softened filtered water averaged 55 parts per million with 5 parts per million of caustic alkalinity or excess lime. Very close supervision of operation is required to reduce the carbonate hardness to the theoretical solubility limit. It is not, however, especially difficult to control the process so as to reduce the carbonate hardness to say 30 parts per million. At the Columbus plant the average carbonate hardness of the filtered water during the past three months has been 30 parts per million instead of 55 parts per million as a general average over 19 years. The difference between 55 parts per million and 30 parts per million is 25 parts per million. In other words the hardness removed because of the use of the process amounts to 25 parts per million. To accomplish this 1.7 grains of additional lime are required. 1.7 grains equals 243 lb. per million gallons and at $6.71 per ton, amounts to 81 ct. per million gallons. If this hardness was not removed by the use of this process, then to meet the standard of hardness maintained at the Columbus plant, it would be necessary to remove the equivalent of this hardness with soda-ash or by the use of zeolite. To remove 25 parts per million with soda-ash at $27.62 per ton, the cost per million gallons amounts to $3.14. The saving per day, indicated by these large scale operations at Columbus, is the difference between $3.14 and 81 ct. multiplied by 30 million gallons per day, or $69.90.

To remove 25 parts per million with zeolite 0.35 lb. of salt per 1,000 grains hardness removed and salt at $6.50 per ton, the cost per million gallons amounts to $1.67. In addition to the cost of salt there would also be some extra expense for wash water.

Recarbonation Decreases the CO_2 Content of the Water.—The question is often asked: Will the addition of CO_2 gas required to recarbonate water increase its corrodibility? The answer is

*Ohio Conference on Water Purification, 7th Annual Report.

†Private communication.

Table I

	Raw	Outlet Mixing tanks	Recarbonated*	Settled	Filtered
Methyl alkalinity	145	64	70	54	22
Phenol alkalinity	0	49	30	25	9
Caustic alkalinity	0	35	0	0	0
Total hardness	165	93	98	83	52
Magnesium	20	....	....	....	2

Raw Water		Filtered Water	
Total alkalinity	187	Total alkalinity	20
Total hardness	210	Phenol alkalinity	9
Magnesium	20	Total hardness	48
		Magnesium	2

no, unless not applied as hereinbefore related. There is less carbon-dioxide in the water so softened than in uncarbonated softened water as previously softened at municipal water softening plants. That is of course not true where the excess lime and soda treatment is practiced as by railroads and industrial plants.

To explain why there is less free CO_2 in overtreated recarbonated water than in ordinary softened water without recarbonation, it is necessary to explain that CO_2 may exist in water in three forms. Free, half-bound and bound. For example: The average alkalinities of the filtered water at Columbus, for the past 19 years were as follows:

Total alkalinity	55
Phenolphthalein alkalinity	30
Caustic alkalinity	5

This water contained CO_2 as follows:

Free CO_2	0
Half-bound	0
Bound	22
Total	22

The softened recarbonated water at Columbus on March 24, 1929, using excess lime followed by recarbonation shows CO_2 as follows:

Free Co_2	0
Half-bound	.9
Bound	10.1
Total	11.0

In other words, the second analysis on recarbonated water shows only half as much CO_2 as the first analysis of water which was not recarbonated.

Disadvantages of Process.—Recarbonation was developed for the purpose of stabilizing lime softened water.

Filter sand incrustation, deposits in mains and meters in Columbus has already been described.**

The question now arises: Have the benefits of recarbonation as originally used been lost by using it as herein described?

In so far as the operation of the filters is concerned it has.

Effect of the Process on Sand Filters.—As shown by the results given, from 25 to 30 parts per million of hardness is removed by being deposited on the filtered sand. In time the sand grains will become incrusted just as they did formerly at water softening plant before recarbonation was developed. Judging from the rate of growth of the filter sand at Piqua, unless some means of removing the incrustation is employed, it would probably be necessary to replace the sand after about 10 years of operation. It is estimated, however, that even if the sand has to be renewed in ten years, it is still economical to use the process because the saving in softening chemicals will more than pay the cost of sand replacement.

Although the water incrusts the sand grains, the water leaving the filters is apparently stable. After two years of operation at Piqua, several taps were made in the water mains and no incrustation was visible. A number of meters were removed for examination and no deposits were found.

At Delaware, O., where this process is being used and where there is already incrustation in the distribution system, a second dosage of carbon-dioxide is applied to the water after filtration. The purpose of this additional carbon-dioxide is to make the water sufficiently corrosive to dissolve some of the carbonate already in the mains.

Schemes Being Tried to Throw the Burden Off the Filters.—Various methods of removing this burden from the filters are being tried. At Piqua the incrustation has been removed successfully by taking the filter out of service after two or three months' use and then allowing the highly acid water from the carbonation scrubber to flow up through the sand and out through the wash water troughs. After two or three weeks of this treatment the incrustation has been dissolved and the filter is again ready for service.

The calcium carbonate formed by the recarbonation in this method of treatment will crystallize out and settle if sufficient settling time is provided. Tests to determine the minimum time are now being made.

Experimental results indicate that the reaction will go to completion much more rapidly if the softened water is agitated after being recarbonated.

Return of sludge, the addition of coagulating materials and filtration through coarse filtering materials are some other schemes that are receiving attention.

Acknowledgment.—The above is an abstract of a paper presented June 27 at the 49th annual convention of the American Water Works Association.

Piecemeal City Planning

In spite of the rapid development of city planning one of the shortcomings of American municipalities is found to be the lack of a comprehensive plan, by Gardner S. Rogers, city planning expert, Assistant Manager of the Civic Development Department of the Chamber of Commerce of the United States.

"Proper municipal development," he said in an address to the Southern Commercial Secretaries' Association, "is not a series of unrelated projects developed when demanded by necessity or political expediency, but rather one comprehensive project in which each individual part has a definite relation to the whole.

"The builder of an office building would not complete the structure and later tear down walls and partitions to add the necessary plumbing and lighting fixtures, yet many cities lay concrete pavements to be torn up later for the purpose of extending or enlarging water or sewer mains. A large office building would not be located on a farm two miles from the center of population because farm land was less expensive than city property, but school boards have a habit of choosing inexpensive sites on the outskirts of a town and so far from the children that bus lines must be established to collect them.

"Comprehensive city planning as it is understood today is the foundation of all municipal improvement and when properly executed coordinates all phases of municipal work in one comprehensive whole. Such a plan may be divided into four major divisions; thoroughfares, zoning, recreation and the platting of undeveloped property."

City Building

Cities that are allowed to grow wild without regard to the uses made of them are rapidly diminishing in number, it is asserted by the Civic Development Department of the Chamber of Commerce of the United States.

In a publication on "Zoning," which has just been issued, it points out that although zoning did not begin in this country until 1916, when New York adopted the first zoning ordinances, the practice is now almost universal.

"Today," says the foreword to the Chamber pamphlet, "this conception of zoning is understood in nearly every city and village in the country. In less than 15 years more than 700 municipalities have been zoned.

"The present problem, therefore, is not so much one of education as it is one of procedure. What does a zoning ordinance contain? To what extent does it regulate property, and how are these regulations put into effect? How are safeguards provided for so that injustices to property owners will be eliminated? These and other practical questions are here discussed in outline form."

Micro-organisms in the Lake Michigan Water at Chicago

Their Effect on Filtration and Method for Counting

By JOHN R. BAYLIS and H. H. GERSTEIN
Bureau of Engineering, Chicago, Ill.

A RECORD of the Plankton in the Lake Michigan water at Chicago was thought to be of some value in determining how long each year we may expect short filter runs when the filtration plants are constructed. The Division of Water Safety Control, Bureau of Engineering, has collected samples from the various intake tunnels for microscopical counts during the past several years. The counts have been made at the Chicago Department of Health. At first samples were collected five times each week, but now they are collected only three times weekly. Since starting operation of the experimental filtration plant, microscopical test of the water from the Dunne crib have been made at this plant in addition to those made by the Health Department.

Fairly reliable record of the organisms occurring in the water entering the Chicago intake cribs for the past two years is now available. The prevailing class of organisms is diatoms, the other algae may occur in abundance occasionally. The monthly average of the volume of all organisms is shown in Fig. 1. It will be noted that the peak for 1927 was in May and for 1928 it was in September. It is interesting to note that in 1928 the minimum monthly average was nearly one-half the maximum. It probably is unusual for water in the northern part of the United States to have a January and December volume of organisms of about 500 cubic standard units per cc. (a cubic standard unit is a cube 20x20x 20 micra). The temperature of the water is shown in Fig. 2, and the hours of sunshine are shown in Fig. 3.

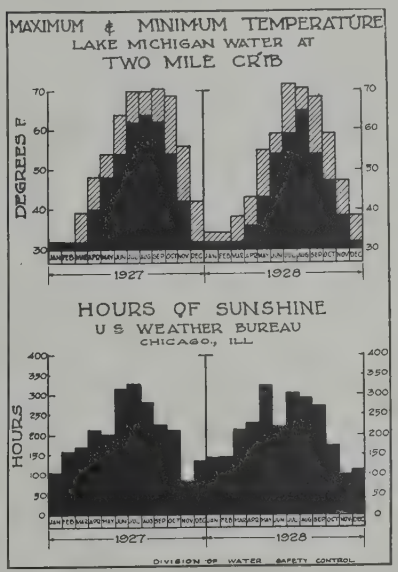

Fig. 2 Upper, Fig. 3 Lower

Figures 4, 5, 6, 7, 8 and 9 show the monthly averages of the 6 organisms occurring in fairly large numbers. It will be noted that Tabellaria may grow abundantly at most any season of the year. It was high from April, 1927, to February, 1928; also high again in October, November and December, 1928. Asterionella usually has its peak in the spring. The peak for Fragillaria seems to occur at most any time of the year. Nitzchia and Melorira usually have their peaks in the spring. Dinobryan, and perhaps most animal organisms, usually have their peaks in the summer or fall. It will be noted from Table I that no animal organism occurring in fairly large number had its peak in the espring. It also will be noted from Table I that the day of highest volume usually occurred in the spring or summer for the diatoms and in the latter part of the year, from August to December, for the green algae. The counts at the experimental plant correspond fairly well with the counts made by the Health Department.

Tastes and Odors. — Objectionable tastes and odors have not occurred in the Chicago water as often as might be expected from the large number of organisms present. There seems to be no reliable information as to how many organisms of the taste-producing kind are necessary to impart a taste to water. If there are 200 or 300 cubic units of a certain organism present we have little information as to whether this is near the taste-producing point or whether the water may contain many more without danger of taste or odor. The writers therefore can give very little information along this line.

There have been several periods during the past few years in which there were tastes readily noticeable in the Chicago water. The following is taken from the 1926 report of the Division of Water Safety Control:

"Beginning about the first of July, 1926, and continuing for over three weeks there was a marked grassy to objectionable fishy taste in the public water supply throughout the city. The cooperation of the U. S. Public Health Service was enlisted in studying the cause of this condition. Assistant Limnologist Milton S. Foreman, attached to the Stream Pollution Office of that service at Cincinnati, O., was detailed by the Surgeon General on July 15 to assist in the investigation. The most offensive condition existed between July 7 and 10, during which time hundreds of complaints were received from citizens in all sections of the city. Continuing throughout the summer, and even as late as the first week in Sep-

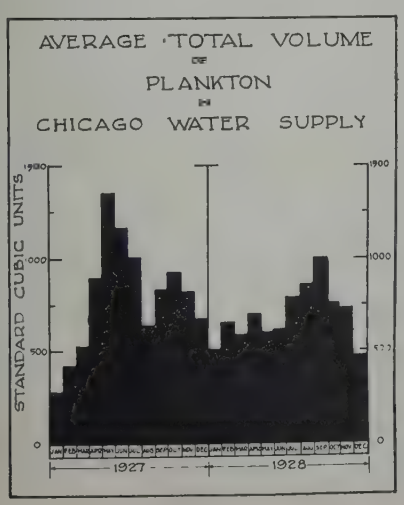

Fig. 1

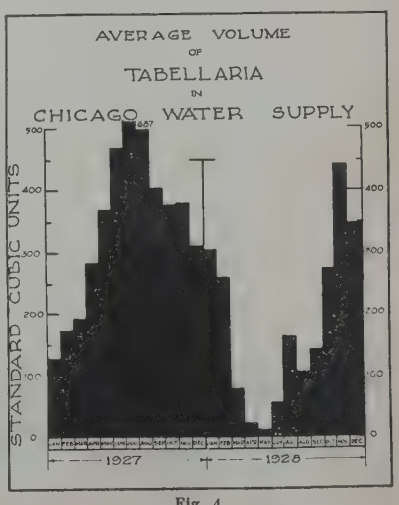

Fig. 4

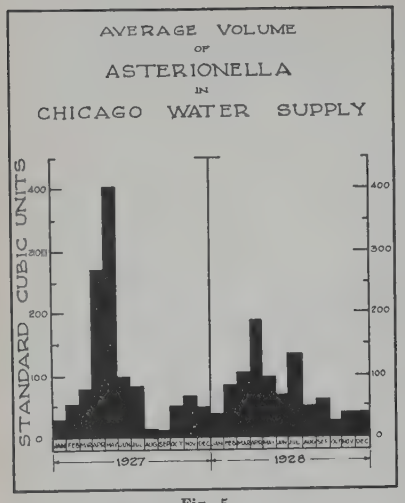

Fig. 5

tember, a noticeable grassy to fishy taste persisted in the water supply."

The microscopical counts during the days of excessive taste showed the presence of about 250 cubic units of Dinobryan per cc. At this time the entire volume of the cluster of organisms was measured, consequently the volume given was greater than the true volume.

The 1927 and 1928 reports each record a period of taste. "There was a noticeable fishy taste in the water in July, 1927, and in the early part of August, which was attributed to the presence of large numbers of Tabellaria." From the 1928 report there is the following: "During the first few days in July a taste was noticed in the water supply which was probably caused by the marked increase in Dinobryan."

Effect of Micro-organisms on Filtration.—It is not necessary to tell most filter operators that microörganisms cause a shortening of the filter runs, for this is the most serious operating trouble in many plants. Many perhaps are already familiar with how the organisms actually cause short filter runs, but there is little specific information in the water works literature on the subject. One of the writers (Baylis) has made observations for a number of years on the things that affect filter runs, which, it is hoped, will throw a little more light on the subject.

First we should consider how a sand filter actually removes the suspended matter from water. In this paper the discussion will be limited to water that has been coagulated as is customary practice in rapid sand filtration. It is evident that the voids in the sand bed of a rapid sand filter are much larger than many of the particles of coagulated matter, yet all the particles are filtered out without difficulty. This is due largely to a lodgement of the particles in the wedge of the void where two sand grains touch. Ordinarily there is considerable penetration of the coagulated matter into the sand beds when sand of about 0.3 mm. diameter or larger is used. This is what we hope to accomplish, for when the filtration is largely on the surface of the sand bed the loss of head increases very much more rapidly than if the coagulated matter penetrated into the bed. Figure 10 shows typical loss of head curves where there is penetration into the bed and where the filtration is largely in the surface of the bed. It will be noted that the curve when there is penetration is nearly straight whereas the one where the filtration is largely in the surface layer the curve keeps increasing at an accelerated rate.

Certain microörganisms add toughness to the coagulated matter. It is somewhat like adding steel reinforcing to concrete. As the coagulated matter filters out it forms a mat on top of the sand bed so tough that the increasing pressure to keep the filtration rate

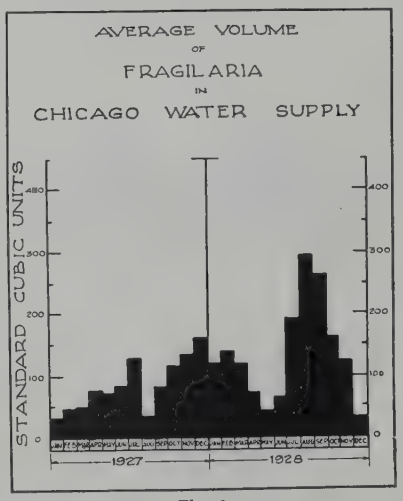

Fig. 6

constant does not force it through the voids in the sand at the surface as is the case where no organisms are present. Figure 12 shows camera lucida drawing of coagulation containing entrapped microörganism, and Fig. 13 shows the more compact mat formed on the filter surface. It is evident that the mat actually formed at the filter surface is much thicker than that shown by Fig. 13, but a thin section that would allow light to pass through had to be used for making the drawing. The mat will vary in toughness with the kind of organism present. Long filamentous organisms are more effective in adding toughness to the coagulated matter than the short or spherical organisms. In most instances when extremely short filter runs occur filamentous organisms are the main cause, however an enormous increase of certain organisms like Asterionella or Tabellaria may cause very short runs.

There are instances where spherical or nearly spherical organisms have been thought to be the cause of the short runs. Some organisms of this kind appear to break up and form a gelatinous substance in the water that is much tougher than the gelatinous precipitate of alumina or iron. There are also instances where a comparatively small volume of the organisms reach the filter beds, yet the runs are short. This is believed to be due largely to the presence of gelatinous matter that results from the decay or breaking up of the organisms back in the reservoir before the water reaches the filtration plant.

There are two ways in which filter runs may be lengthened when microörganism are the cause of the short runs. The organisms must be removed before the water reaches the filter beds, or the water must be filtered through a bed of coarse material before going to the main sand filters. It might be possible to add a few inches of light coarse material on top of the sand and produce somewhat the same results as double filtration. The coarse material should contain voids large enough that a mat cannot form on the surface, yet it must be capable of removing a large percentage of the coagulated matter.

It is believed that sedimentation offers the most practical means of removing microörganisms in most instances. Where the water goes through storage reservoirs of several days capacity prior to chemical treatment and filtration, chlorine or copper sulphate may be used to kill the organisms. Then many of them will gradually settle to the bottom. When it is not possible to do this and it is necessary to take the water as it comes to the plant a quick settling flocculation must be produced. This may be done by adding suspended matter to the

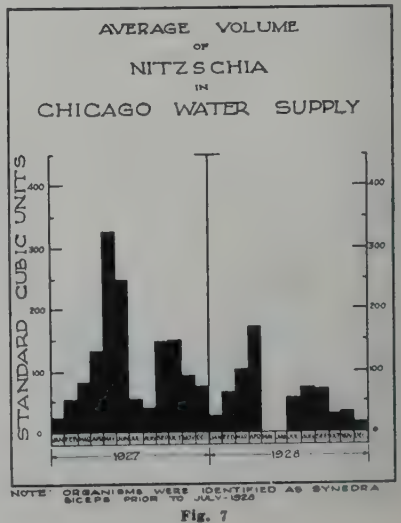

Fig. 7

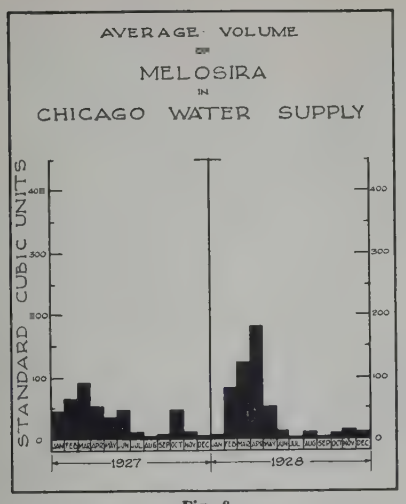

Fig. 8

water as Lovejoy[1] has done at Louisville by the addition of an excess of coagulant, or the production of an artificial turbidity by softening with lime. Local conditions will largely determine the most effective means of handling the situation. The point that should be stressed is that all plants subject to short filter runs should be prepared to handle the situation in some manner and not let the filtration plant operate at decreased efficiency part of the time.

Most of the plants handling the Great Lakes waters are troubled with microörganisms producing short filter runs part of the time. Usually a storage reservoir of a few days capacity separate from the lake is not provided. The organisms probably can be handled best by precipitating them with the coagulated matter. The organisms themselves have very little tendency to settle, or they would not be in the water. Aluminum hydroxide coagulation also is very light and does not settle rapidly even though an excess is used. To produce a rapidly settling coagulation there must be an increase in the turbidity. This may be done by adding mud to the water, or by forming a crystalline precipitate in the water. The fact that the Great Lakes water is fairly hard and is already saturated or nearly saturated with calcium carbonate, it seems that the most economical thing to do is to add lime to the extent of producing a calcium carbonate precipitate that will increase the turbidity to 50 or more.

Method for Counting.—The Chicago Health Department laboratory uses the procedure as outlined in Standard Methods of Water Analysis, except that coarser sand is used for filtering the water. This is due to the difficulty in filtering through the desired amount of the sample within a reasonable time. To avoid this trouble and to eliminate the error in concentrating, the experimental filtration plant makes a direct count without concentrating unless the counts are very low. This procedure will be outlined.

* Prior to May, 1928, Nitzchia was identified as Synedra biceps.

For counting the small organisms, 1 cc. of the water is placed in a Rafter's counting cell and allowed to stand about 10 minutes before starting the count. Practically all the organisms settle to the bottom of the cell within this time. There are a few species that float and will come to the top of the cell, but such organisms are rarely present in most waters. The count is made by focusing the microscope on the bottom of the cell and starting at one end. The cell is moved gradually towards the other end with the mechanical stage and the organisms are counted and measured as they are passed over by the ruled portion covered by the eyepiece micrometer. This should be repeated across the cell until a sufficient number of organisms have been counted to give fairly good indication of the number present. In addition to this it is desirable to go across the cell a few times with the focus at the top so that floating organisms will not be missed. If the magnification is such that the ruled

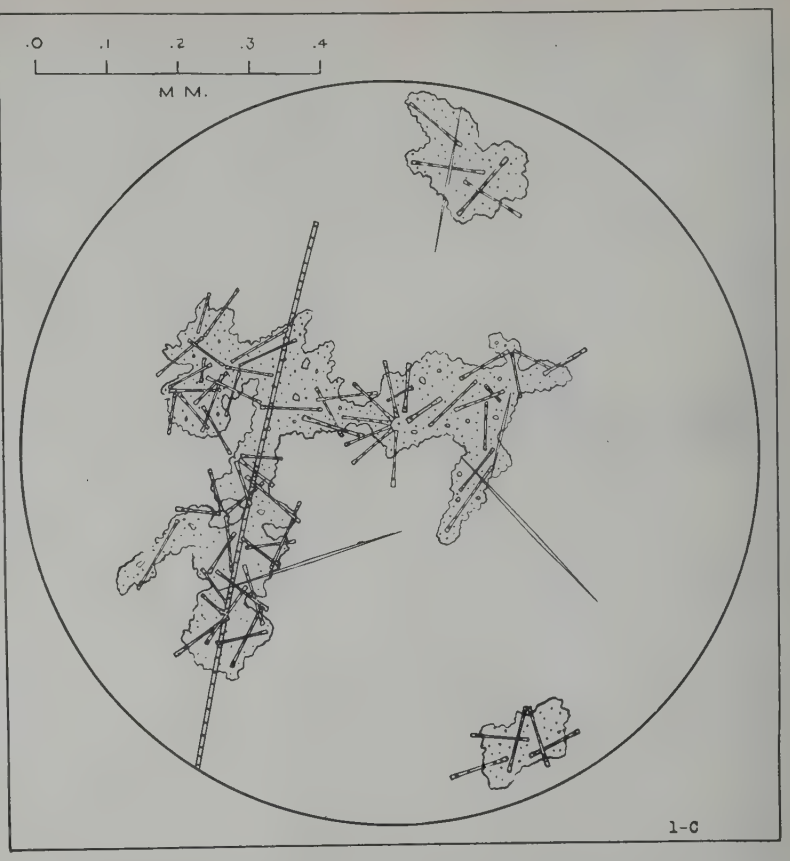
portion covers one square millimeter, passing from one end of the cell to the other (the cell is 20 mm. wide and 50 mm. long) is one-twentieth of a cc. When the counts are high, passing across the cell once may be sufficient, but when only a few are present it may be necessary to examine the entire cc. of water. In fact when there are less than 25 organisms present the samples should be concentrated.



MICROÖRGANISMS ENTANGLED IN ALUMINUM HYDROXIDE COAGULATION
Fig. 12

The examination for large organisms is made by concentrating and examining in a 10 cc. cell. This cell is 50 millimeters long, 40 millimeters wide, and 5 millimeters deep, inside dimensions. It is constructed in the same manner as the Rafter's cell. Instead of filtering the water through sand No. 20 silk bolting is used, being made in the form of a cylinder about 4 in. long and ½ in. in diameter. This is attached to the bottom of the filtering funnel and the desired amount of water filtered through. The water passes through the cloth quite rapidly and most any amount desired may be filtered within a very short time. When a large number of large organisms are present 2 to 5 liters are filtered.

After the water has filtered through, the plug on the bottom of the cloth cylinder is removed and the catch washed through with slightly less than 10 cc. of water. It is then diluted to 10 cc. and placed in the large counting cell. The 48 mm. objective is used and the procedure for counting and estimating the volume is the same as for the small cell, except there is a different factor for the area covered by the ruled portion. It may be necessary to kill the organism to prevent them from moving about while the count is being made. As a rule only such organisms as measure about 150

100	65.449	98.17

To obtain the volume of organisms with diameters larger than is shown by the table, look for the volume one-tenth the diameter and move the decimal point three places to the right for spherical organisms and two places for cylindrical organisms.

micra or more in diameter are counted. This will include Daphnia, Cyclops, Hydra, Bryozoa, large protozoa and rotifiers, worms, etc. Daphnia and Cyclop frequently occur in numbers that cause a shortening of the filter runs, yet the procedure as outlined in Standard Methods of Water Analysis does not insure an accurate estimate of the number and volume of such organisms. The method of concentrating by filtering through cloth was developed by John H. Mills, bacteriologist at the experimental plant.

One of the writers (Baylis) has used the direct method of counting for a number of years and prefers it to concentrating the samples. It is more accurate and usually involves less labor than the concentration method. Table II shows comparison of the direct count with the concentration method as outlined in Standard Methods. It is seen that the direct count gives a slightly larger number of organisms.

It is believed desirable to state how the measurements of the organisms are made, especially as there seems to be no uniform procedure for such measurements and different workers may vary greatly in the volume measurement for certain species of organism. Some workers will take the entire area within the circle of a characteristic spoke-wheel cluster of Asterionella cells, whereas the actual volume is the sum of the volumes of the individual cells. A cluster of Dinobryon is sometimes measured as the outside dimension of the cluster, yet it is evident that the true volume is that of the cells only. With the various procedures now used it is difficult to compare the results from two laboratories. The procedure as used by Baylis will be given.

The volume in cubic standard units for various size organisms is given in Table III. It provides for measuring the organism as a sphere or cylinder. If the organism is nearer a sphere than a cylinder its spherical diameter is estimated and the volume obtained directly from the table. If its length is considerably greater than the diameter it is measured as a cylinder. The length and diameter are determined and the column for cylindrical organism used. The figures are based on a cylinder 100 micra (0.1 mm.) in length. The volume is quickly computed from the table but is not given unless the length happens to be 100 micra. Assume that an organism is 150 micra in length and the average diameter is 12 micra. The table gives 1.41 cubic standard units for the volume of an organism this diameter 100 micra in length, consequently the total is 2.17 units.

Such organisms as occur in clusters that are easily broken apart are counted one organism for each cell. This includes Asterionella, Dinobryon, Fragellaria, Synedra, Bryozoa, and others. Organisms that occur in filaments such as Melosira, Oscillatoria, Anabaena, Aphanizomenon, Ulothrix, and many others are called one organism per 100 micra of length. A melosira 800 micra in length is recorded as 8 organisms.

A record sheet as shown in Fig. 14 is used. The advantage of this kind of a record becomes apparent. Assume that there are 8 attached cells to a cluster of Asterionella. Eight is recorded as a numerator, and the total volume of the eight cells is recorded as the denominator. One can tell from the sheet just how the Asterionella occurred, for when there is an individual cell it is recorded as one and when there are two or more attached the number is recorded. Such a system of recording is advantageous for recording Asterionella, Fragillaria, Tabellaria, Dinobryon, and in fact all organisms that may occur either single or in clusters. It is particularly advantageous for filamentous organisms, for the length of the filament may be obtained from the record. Assume a filamentous organism is recorded 7.5 organisms and 15 cubic standard units. The organism is 750 micra in length and 15 micra in diameter. The length of the filament has considerable bearing on its effectiveness in causing filter clogging. In studying operating records one may refer to the original sheets and determine the size of all organisms counted.

an abstract of a paper presented at the 49th annual convention of the American Water Works Association, held June 24-28 at Toronto, Ont.

Snow Melted in Cooling Pond of Power Plant

The city of Westmount, Que., melts the snow gathered from the city streets and walks in the cooling pond of the municipal power plant. The pond was built for the purpose of cooling hot water from the condensers of the steam plant. To facilitate the melting of the snow, which is dumped from the trucks in which it is collected, steam lines are carried directly from the boilers to the pond where they discharge below the dumping space provided for the trucks. About 40 per cent of this steam is derived from the destruction of garbage and if the heat units so obtained be disregarded, the average cost of melting snow is less than 20 ct. per load of about 9 cu. yd.

Training Schools for New York State Municipal Employees

A comprehensive program for the training of all groups of municipal officials and employees was adopted at a recent meeting of the Advisory Committee of the Conference of Mayors and Other Municipal Officials of the State of New York.
